The specimen is now ready to embed in its macroscopic cup. The cups (see cut) in use in this institution are 1⅞ inches in diameter by 15/16 inch deep, made of crown glass, upper surface highly polished and edge ground true.

Remove the surplus glycerin and water from the specimen and deposit it in the cup, cut surface up. Fill the cup with warm (not hot) jelly, tease out with warm needles all the air bubbles that have become imprisoned, turn the specimen over, press it firmly on the bottom of the cup, examine over a mirror, center and retain it in position by means of a small piece of cigar box (⅝ by 2 inches), through the center of which an ordinary pin has been driven. It is not necessary that the pin should penetrate the specimen, but it should be long enough to permit the greater part of the weight of the piece of wood to be transferred to the specimen at the point of the pin. If the mount is satisfactory place it under a bell-jar to exclude dust, and with it a piece of absorbent cotten saturated with about a dram of formalin.

The statement has been made several times that the exposure of nutrient jelly to the vapor of formalin renders it insoluble by heat. Formalin vapor, free under a bell-jar, will render the surface of glycerin jelly in macroscopic cups denser to a very slight depth, but not wholly insoluble. A cup of jelly so exposed for five days could still be completely melted in an Arnold sterilizer, with the exception of a very small ring at the margin of the cup.

Although formalin vapor acting on glycerin jelly under a bell-jar does not render the entire mass insoluble, no mean advantage is gained by its use, as a greater degree of heat is required to cause it to "run" and displace the specimen. In fact, I have frequently noted liquefaction of old mounts during the summer months when the thermometer stood at 98 or 99 F., although the usual melting-point of normal glycerin jelly is about 105 F.

It would seem hardly necessary to call attention to the fact that pathologic specimens should not be exposed to a greater degree of heat than is absolutely necessary; but this should particularly be borne in mind with reference to the eye, as immediately the limit of heat is reached (and the degree is comparatively low), the globe, or hemisphere, will suddenly collapse and be damaged beyond hope of repair. Therefore, if there is any likelihood of necessity arising for redissolving the glycerin jelly surrounding a specimen, we would advise against the use of formalin for "setting" the jelly.

After standing for two or three days, the cup should be sealed to prevent further evaporation. We have found the most satisfactory material for this purpose to be porcelainized glass. It is pure white, and greatly improves the appearance of the specimen. It is attached to the bottom of the cup with Stratena or Major's cement, applied hot. A celluloid disc answers the same purpose, but it is not pure white, and we have been unable to find a satisfactory cement for it.

The mount has now been completed and can be filed away, but we prefer to still further protect it by cementing it into a square wooden base. These blocks are made of mahogany, and are countersunk in the middle about a quarter of an inch.

It is occasionally an advantage to cement a lens to the upper surface of the cup to show a foreign body, or anything of especial interest located below the surface. For ordinary specimens, however, we consider a permanent lens a useless expense, and, in the majority of cases, a disadvantage. When applied, for which Canada balsam should be used, the lens should be warm, and, of course, the surface absolutely clean.

The accompanying full-size outline cut shows all the parts referred to, and their relations.

Specimens prepared in this manner, if properly sealed, should remain in perfect condition indefinitely; but it will occasionally happen that the cement may not have perfectly attached the disc to the cup, and slow evaporation will occur. This will sooner or later be manifested by fissure of the gelatin, necessitating remounting if the fissures can not be filled with fresh jelly without imprisoning air. A good result can be obtained by cutting away the jelly about the specimen with a sharp knife, leaving smooth surfaces and the specimen *in situ;* then refill the cup with warm jelly. In case air has found its way under the specimen, cut off the upper surface of the jelly and melt with very gentle heat (not over 112 F.) and remount as before.

The well-known fact that exposure to light tends to darken gelatin suggests the advisability of shielding the mounted specimens from strong light especially.

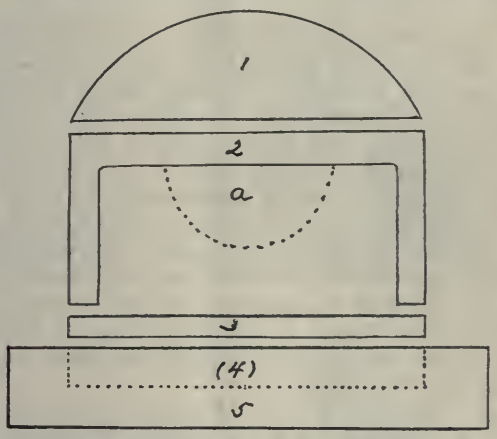

Fig. 2.—Full-size outline figure of macroscopic cup and accessories (Dixon). 1, Lens; 2, macroscopic cup; 3, porcelainized glass disc; 5, mahogany base showing (4) portion countersunk for reception of 2 and 3; (*a*) specimen.

July 1, 1903.—About the only modifications made in the foregoing methods since its publication consists in the more thorough drying of the specimen with calcium chlorid under a bell-jar, and a change in the manner of cementing the bottom on.

For this purpose we use Bell's cement, sometimes Major's cement, and sometimes Stratena. After the cement has thoroughly set we give the joint two or three coats of zinc white, allowing each to dry thoroughly, and then for a finish apply a ring of asphalt. The latter is, however, not necessary.

Care should be taken not to expose the specimen too long to formaldehyd, as a reaction is likely to occur rendering the jelly opalescent. This causes no special damage, but the jelly ceases to be sparkling.

The disadvantage of the method is that in very hot weather the jelly may become liquid in a few specimens, but this has been largely obviated by turning the specimens upside down.

The advantages are that the natural colors can be in the main preserved, all the parts are held in their normal

positions by the density of the medium, they are readily photographed, and they can be transported with safety; beside a globe damaged during laboratory manipulation can be restored with a little patience and a hot needle.

Dr. Harold G. Goldberg (Wills Eye Hospital, Philadelphia) prefers the formalin-glycerin-jelly method modified as follows: Gelatin (best French) oz. i. Cut in small strips and soak in water for twelve hours, pour off water and dissolve in solution (x).—Glycerin, fl. oz. viii; water, fl. oz. viii.

Egg albumin, fl. oz. vi; thoroughly break up in graduate with spoon and mix with fl. oz. iii of sol. marked x, which should be hot when mixed. Filter through flannel into remaining sol. marked x, and mix thoroughly; place on water bath and after coming to boiling point, allow solution to simmer without stirring for five minutes until all the albumin is coagulated. Filter through hot water funnel, or anything that will serve the same purpose, and add 30 m. of pure formalin, a drop at a time, stirring after each drop to prevent lumps forming; then cool.

This jelly is almost colorless, transparent and very firm, and is not melted by summer heat; in fact, after the jelly is several months old it is very difficult to melt it, even by prolonged exposure to the heat of a water bath.

In cases where the tissues are thoroughly impregnated with about 10 per cent. formalin solution before mounting, the additional formalin causes the jelly to contract, as it grows older (possibly over a period of several months), squeezing the water contained in it from its substance. This collects on the surface in drops; therefore, I do not permanently seal the lid of the cell until this complete contraction has taken place, nor do I quite fill the cell with jelly, allowing sufficient space for the water to collect. After this contraction has taken place, it is impossible to melt the jelly with even the actual flame; it will burn, but not melt, and if it becomes necessary to remove the tissue the jelly must be dissolved away.

Tissues hardened in 5 or 10 per cent. formalin solution having remained in the solution several days, may be frozen, cut and mounted without any further preparation.

If tissues hardened by the other methods, after having passed through the alcohols, are placed in a 5 or 10 per cent. solution of formalin for twelve hours, their preservation in the jelly will be more complete and permanent.

When the tissues are impregnated with the formalin solution, a capsule 5 or 6 mm. in thickness is formed around the eye, due to the hardening action of the formalin on the jelly. If the vitreous chamber is not already filled it will be occupied by a mass of tough jelly which preserves the form of the globe.

In any event, all alcohol must be removed from the tissues before mounting in the jelly or air bubbles will form around the tissues and spoil the appearance of the mount. I have mounted a number of eyes that had remained in 10 per cent. formalin solution only twelve hours. These were frozen, cut and mounted in the jelly immediately, thus practically preserving the first changes noticed. I believe it is possible (although I have never had an opportunity to try it) to preserve a perfectly fresh specimen in the jelly without any preparation whatever.

I obtain my mounts (the ordinary cut glass dishes, with white covers) from Wall & Ochs, opticians, Philadelphia. The jars are sealed with common white photographic paste (which is easily removed) until contraction has completely taken place. Then the water, which I have described as collecting for months, is removed and the jars permanently sealed with xylol-balsam.

The advantages of this jelly, beside those I have already mentioned, are that it is a preservative for the tissues, which can be removed from it within several months, or possibly longer, and cut and stained for microscopic study. It also fixes the natural color of the tissues and is easily prepared. I have some specimens that I placed three years ago in this jelly that are quite as good to-day as when first preserved.

Dr. Allen Greenwood, Boston, does not claim originality for the method he prefers.

In order to preserve the colors he hardens the enucleated eye by the Kaiserling method as follows:

1. Fixation for 1 to 4 days in

Formaldehyd	200
Water	1,000
Nitrate of potassium	15
Acetate of potassium	30

2. Drain and place in 80 per cent. alcohol for 1 to 6 hours, then in 95 per cent. alcohol for 1 to 2 hours to restore the color.

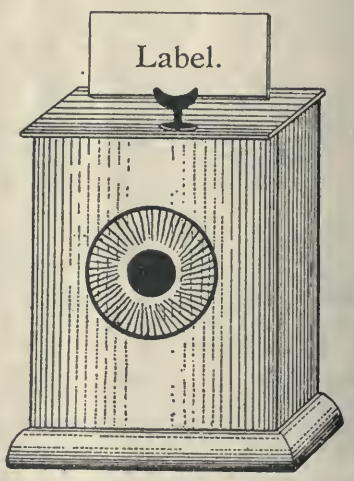

Fig. 3.—Jar for museum specimens (Greeff).

3. Preserve in

Acetate of potassium	200
Glycerin	400
Water	2,000

Fixation should be performed in the dark and the specimen kept in a dark place.

To section the eye it is first frozen by packing in pounded ice and salt.

The half eye to be mounted is then placed in the glass dish with the cut surface down and the melted glycerin jelly poured in. If the glass dish is put on ice the layer of jelly next to the specimen will harden and the eye be held in place until the whole mass is hard enough to prevent the eye from floating. The dish should be filled full enough to exclude all air bubbles when the lid is applied. After the jelly becomes hard the lid is sealed on with Canada balsam.

The jelly is made as follows from a formula given by Dr. Verhoef.

Best French gelatin (Coignet's gold label)	30 grms.
Cold saturated boric acid sol.	240 c.c.

Add 80 c.c. of glycerin and the white and shell of an egg, heat in a water bath, add 1 c.c. of glacial acetic acid

to precipitate the albumin, boil thoroughly for some minutes and then filter three or four times. Put the filtering apparatus in a steam sterilizer to prevent hardening of the jelly.

PERMANENT PREPARATIONS IN FLUID PRESERVATIVES.

Once surrounded by and impregnated with jelly, it is with great difficulty and small satisfaction that the bulbar hemisphere is utilized for microscopic purposes. This drawback can be obviated by its preservation in suitable fluids. The best known method is that of Greeff, a cut of whose jar for museum specimens is here given. A description of this form of preparation will be found in this author's small primer,[3] *Anleitung zur*

Fig. 4.—Jar for mounting gross eye specimens (Thomson).

mikroskopischen Untersuchung des Auges, 1898, pp. 67, 69.

A number of modifications of the original method have been proposed by various pathologists, both as regard the form of the glass receptacle and the preserving fluid.

Dr. Edgar S. Thomson (Manhattan Eye and Ear Infirmary) advises that the specimen, after a thorough

Fig. 5.—The Specimen held in position by a glass rod (Thomson).

washing, be hardened for 24 hours in formalin, 4 per cent. The globe is then bisected, and the piece intended for mounting is wrapped in absorbent cotton, to prevent shrinkage, and immersed for three days in the following solution:

Acetate of soda	3
Kali chlorid	5
Formalin	10
Water	100

The specimen is then wrapped in a fresh piece of cotton and immersed in alcohol varying between 80 and 95 per cent., depending on the strength and resistance of the specimen to shrinkage. The alcohol should be as strong as possible. It is immersed in this for twenty-four years, and finally is soaked for two or three days in the following solution:

Acetate of potash	90
Glycerin	180
Water	300

After which it is mounted in a fresh solution of the last formula.

The jars (see cuts) are from E. B. Meyrowitz of New York city. Dr. Thomson has not been in the habit of sealing the jars, finding that with glycerin preparation air bubbles are not apt to appear. The advantages of the method are as follows: It preserves the color and gives proper transparency to the cornea and lens and the specimen can be removed from the jar at any time and a section made, although these are not as satisfactory as fresh sections, on account of the shrinkage which the glycerin causes; it is nevertheless possible to make them,

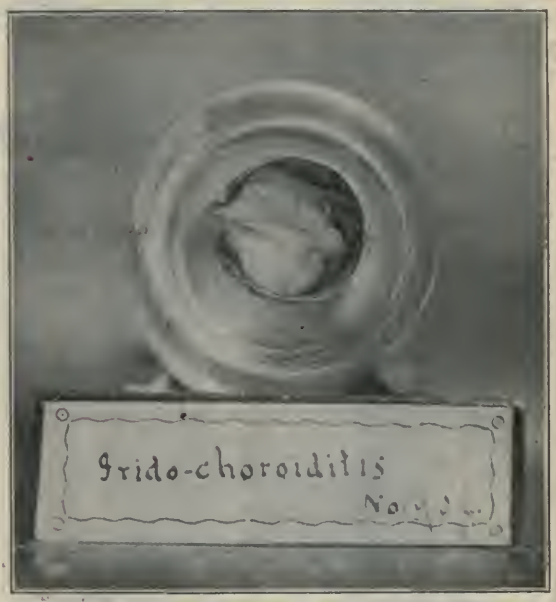

Fig. 6.—The specimen on the block for exhibition (Thomson).

which can not always be said of the glycerin-jelly specimens. The method is simple, and specimens prepared three years ago have kept very well.

Dr. E. V. L. Brown (Illinois Eye and Ear Infirmary) describes "The Technic and Advantages of the Greeff Method of Mounting Macroscopic Eye Preparations" as follows. One needs, in addition to the glass jar shown in the accompanying cut, the following:

1. A 3 per cent. formalin or Kaiserling solution.

2. Some gelatin glue. Dissolve three or four strips of ordinary cooking gelatin in an equal bulk of water and boil until the mass is thick and tenacious. It is then ready for use. On cooling, the solidified mass may be preserved for future use by adding a little alcohol; heat will promptly liquefy it.

3. Some shellac or japanner's gold size; "liquid glass" to seal the cover. The gelatin glue will answer this purpose very well unless the mount is to be sent through the mails.

The technic is not difficult. Carefully dry the half or one-third section of the eye, lay the jar on its side, put a drop of the gelatin glue inside, and place the

3. English readers will find a good translation of this little book by Hugh Walker, published by Blakiston, 1902, entitled "A Guide to the Microscopic Examination of the Eye."

specimen in position. Allow the glue to harden for fifteen minutes; place the jar upright, fill it with the solution and seal the cover. A small clasp may now be glued to the cover to carry a label or photograph.

The advantages of this method, especially over the Priestley Smith method so generally used in past years, are obvious, namely:

1. The Greeff method is quicker. It takes several days to prepare the gelatin, mount the eye and allow the jelly to harden according to the Priestley Smith method. The writer has mounted as many as twenty eyes by the Greeff method in a single morning.

2. The method is simpler and the mount more permanent. A good clear gelatin of the right consistency which will retain its solidity in hot weather is difficult to obtain.

3. It is cheaper by two-thirds. The Greeff jars may be had of E. Leitz, 34 S. Clark street, Chicago, for 10 cents each. The Priestley Smith jar costs 30 cents,

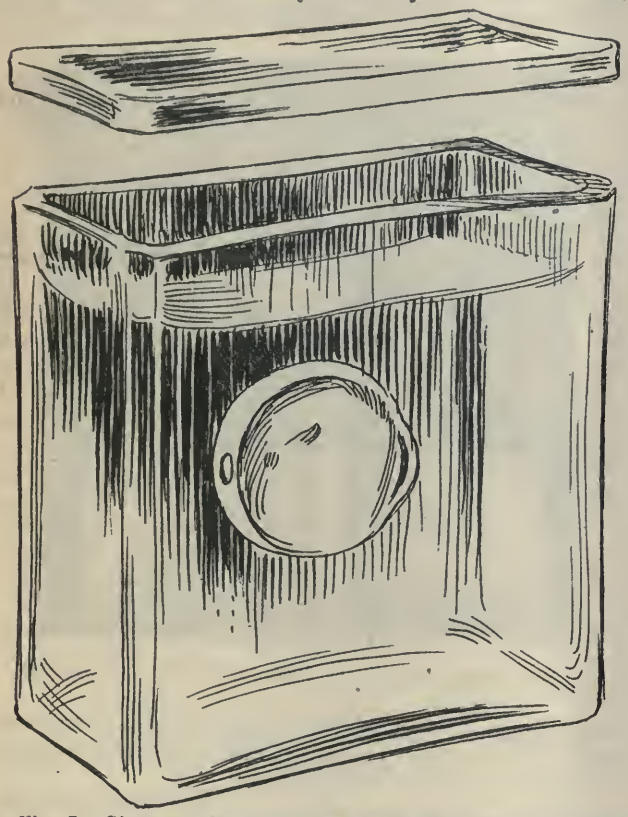

Fig. 7.—Glass jar for mounting macroscopic eye preparations after the Greeff method (E. V. L. Brown).

while good gelatin costs a dollar a package; on the other hand, formalin or Kaiserling solutions are always on hand and inexpensive.

4. The Greeff mount may be kept on a shelf exposed to the light indefinitely, while any gelatin mass will discolor in time.

5. Eyes preserved in formalin or Kaiserling are easier to embed and section for subsequent microscopic study, should this be at any time desired.

Dr. Edward A. Shumway (William Pepper Laboratory, University of Pennsylvania) uses the gelatin mount, as a rule, when it is desirable to make a macroscopic preparation. The gelatin is made in a rather stronger solution than is usually advised—40 grams of gelatin (Coignet et Cie, France, or Conte Fils, Magdeburg, Germany) to 250 c.c. of water. After solution of the gelatin by careful warming, the white of one egg, beaten up in a small quantity of water, is added to the solution, and the whole poured into an agateware pail. This is then placed in an Arnold sterilizer, and boiled vigorously. In this manner the coagulation of the albumin and the clearing of the gelatin are accomplished without danger of burning the gelatin, a very important point, as the least scorching of the vessel around the top of the gelatin will give a brownish discoloration to the mounting medium. It is then filtered through a good quality of filter paper, preferably in a hot water filter, as the percentage of gelatin is very high, and the solution filters slowly. If it stiffens before fil-

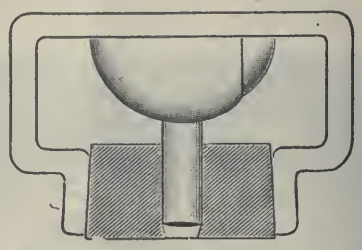

Fig. 8.—Cup, with rounded bases of ebonized wood, for macroscopic specimens.

tration is complete, it may be put back into the sterilizer again, in the agate vessel, and reheated. To the filtrate an equal quantity of glycerin (C. P.) is added, and 1 c.c. of a 2 per cent. solution of commercial formalin (making a dilution of about 1/20,000, which is strong enough to prevent the growth of molds, etc.). The cups are furnished by Wall & Ochs, 1716 Chestnut street, Philadelphia. (See Fig. 8.)

After the gelatin has hardened over the surface of the specimen in the cup it is exposed to the fumes of strong formalin in a covered glass jar, by means of which the surface is hardened to a depth of one-quarter inch.

Fig. 9.—A convenient arrangement for exhibition of macroscopic specimens in the class room, or society meeting. It is composed of a round tray of ebonized wood, to which seven of the wooden bases, used for holding the individual specimens, are screwed. It is made by Wall & Ochs, Philadelphia.

This prevents melting of the surface gelatin, and if, in addition, the cups are inverted, in warm weather, the specimens will rarely be affected. After 24 hours the specimen is removed and allowed to stand under a covered dish several days, and the water which is squeezed out of the shrinking gelatin in the form of drops, over the surface, is removed by filter paper. The cup is then sealed. For this purpose opal glass is used, as it is much cheaper than the "flashed glass," and affords a

better background than transparent glass. The most satisfactory cement I have used is the Imperial Rubber Cement, made by S. C. Moffett, New York, which must be melted in a flame before it is applied, and renders the removal of the disc impossible, unless it is again heated. The danger of evaporation may be further prevented by covering the edge with a ring of asphalt.

Drs. H. V. Würdemann and Nelson M. Black of Mil-

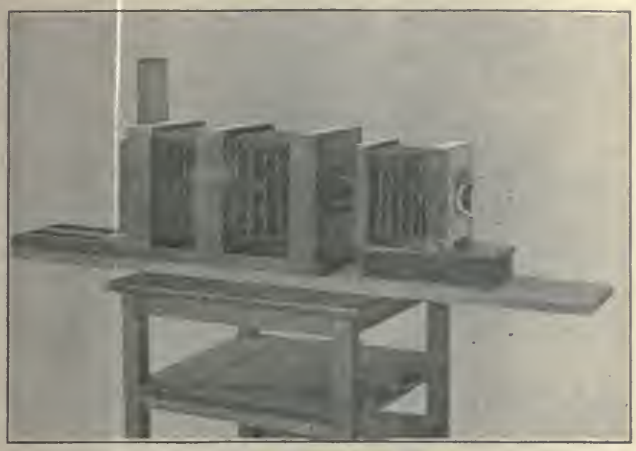

Fig. 10.—The Dixon camera for photographing gelatin-mounted eye specimens.

waukee report that, in their opinion, the two methods of mounting macroscopic eye specimens which seem to give best satisfaction are the glycerin-jelly and the formalin mounting of Greeff. The former has the advantage of being easier to transport without displacing the specimen, but the gelatin has a tendency to become discolored and the preparation of the mount consumes a great deal of time. The Greeff mounting is

Fig 11.—Secondary hemorrhagic glaucoma (Bull). Photograph.

much more effective in appearance, is easier to prepare, can be photographed with much better result, and microscopic specimens can be removed from them at any time, but it has the disadvantage of not standing transportation well.

The following method was first described by Würdemann:[4]

The specimens are first placed in formalin solution (1/10) for 48 hours, then washed with water and hardened in alcohol, beginning with a 33 per cent. solution,

4. Annals of Ophthalmology, p. 674, October, 1897.

remaining a day each in 33, 50, 70 and 80 per cent. solution, respectively, and are kept in the last strength until ready to divide. The eye is then frozen, cut and mounted in glycerin jelly or preserved in a 4 per cent. formalin solution after Greeff's method; or Kaiserling's

Fig. 12.—Anterior staphyloma following ulcer of the cornea (Derby). Photograph of mount.

solution may be used to preserve them in the jar devised by Brown.

Glycerin jelly is prepared by taking 30 gm. of best gelatin (Gold Label, American; Coignet et Cie, France; or Conte Fils, Germany), adding 240 c.c. of distilled water and heating over a water bath. The whites and shells of two white-shelled eggs, or a small amount of Merck's egg albumin, is added and con-

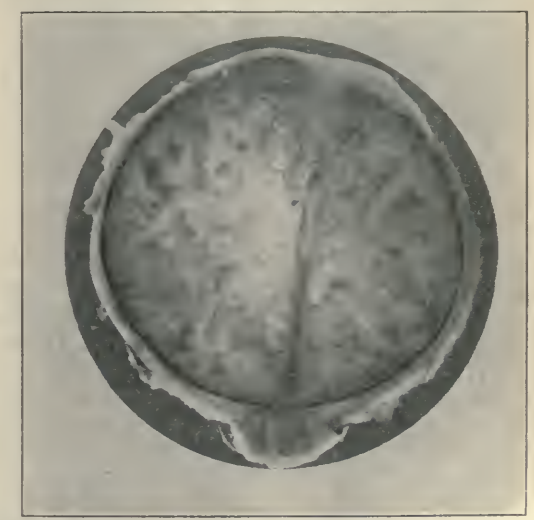

Fig. 13.—Chronic iridochoroiditis following injury twenty years previously (Bull). Photograph of mount.

stantly stirred until the coagulated albumin rises to the top, leaving a clear liquid underneath. Filter through two thicknesses of good filter paper, add an equal volume of C. P. glycerin, 10 c.c. of a 10 per cent. solution of carbolic acid being added to each liter of the jelly to preserve it. The jelly itself is melted by placing the container in hot water, when ready for mounting. The specimens are mounted in small glass jars obtained from Chambers, Inskeep & Co., Chicago. After mounting, the jelly is exposed to the fumes of formalin under a

bell-jar for 48 hours. The glass covers are cemented in place with Freese's cementine, Royal or Le Page's liquid glue.

PHOTOGRAPHING MACROSCOPIC EYE PREPARATIONS.

After an eyeball section has been so successfully preserved and mounted that gross alterations in its tissues are readily distinguished, the question of drawing, photographing or otherwise picturing it naturally arises. Reproduction by photography is, on the whole, the most desirable and most satisfactory method. Dr. George S. Dixon[5] has, among others, discussed its merits as well as its principal difficulties, and, at the request of the committee, has kindly forwarded a number of photographs of gelatin mounts exhibited by him at the New Orleans meeting. Several of these are pictured in the text.

A few trials convinced Dixon that photography of the gelatin-mounted specimens was not as simple as it appeared. The chief obstacle to be overcome was the light reflections from the surface of the glass cup. These produced a good picture of the glass cup, but a very poor one of the mounted specimen. After many experiments it was found that when an ordinary 3½-inch focusing glass, mounted in a metal tube, was placed

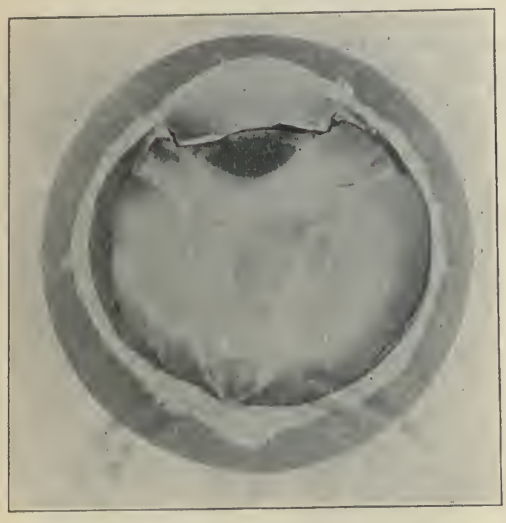

Fig. 14.—Plastic choroiditis (Weeks). Photograph of mount.

over the mount, all direct rays from the surface were excluded, while the eye specimen itself was sufficiently illuminated by light entering the glass sides of the cup. Finally an apparatus was devised which Dr. Dixon regards as the best means of obtaining plates of gelatin mounts. As seen in the figure, it consists of a pair of bellows, the anterior, a single one, being smaller than the posterior. The latter is double and carries the lens and plateholder.

This posterior bellows is securely fastened to a baseboard long enough to project considerably beyond the anterior bellows. The baseboard of the anterior bellows is fastened to a couple of cleats sufficiently high to bring the diaphragm at the back and the object in front, in the optical axis of the lens. Two smaller cleats are screwed to the long baseboard in such a manner as to allow the smaller bellows to be moved backward and forward without lateral motion, independent extension of the bellows on its own baseboard being retained.

The anterior bellows is fitted with a sliding front, in the center of which is a diaphragm sufficiently large for all specimens, varying sizes being supplied with changeable diaphragms of diameters slightly less than the interior of the macroscopic cup, for the purpose of cutting off the direct rays which would otherwise pass through the rim of the cup. This point is essential. A spring is employed to hold the cup in position. As the front slides, it can be removed from the bellows, the object adjusted as desired, and the whole returned to

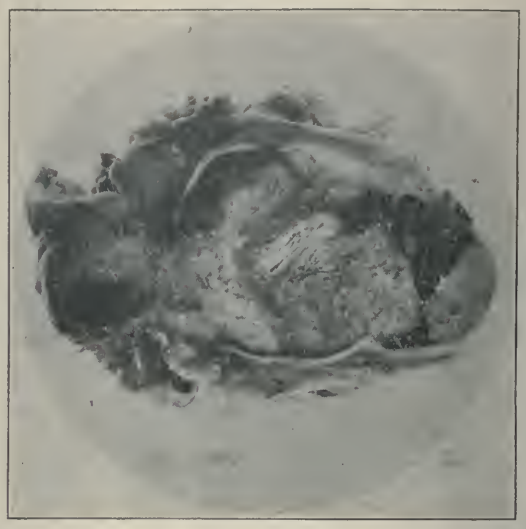

Fig. 15.—Melanosarcoma of the choroid (Noyes). Photograph of mount.

position, when the specimen will be in the optical axis of the apparatus.

The posterior bellows is fitted with a 3¾-inch Gundlach wide-angle lens intended to cover a lantern slide plate, and capable of enlarging an image the size of an eye two diameters with satisfactory detail; an F 32 stop should be employed during exposure.

A wide-angle short-focus Morrison lens, giving an extreme amplification of 2.6 without "breaking," is a

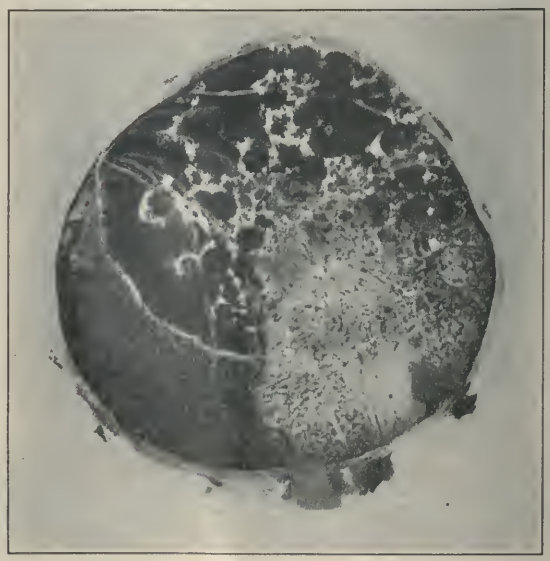

Fig. 16.—Melanosarcoma of the eviscerated globe (Hunter). Photograph of mount.

trifle more satisfactory, but the Gundlach lens answers the purpose fairly well, as over two diameters is seldom desirable.

In the early work with this camera, diffused daylight, preferably in the open air, was employed. The camera as it stands in the cut is in position for exposure. It was soon learned, however, that this method would only

5. New York Eye and Ear Infirmary Reports, 1889.

answer for a limited number of specimens, namely, those presenting a white or a very light substance in the interior of the hemisphere.

Specimens filled with dark tumors, or those in which nothing remained in the interior but retina and choroid, yielded negatives with no detail whatever in the center until the cornea and sclerotic, transparent and white, respectively, were hopelessly over-exposed. To obviate this a white bristol-board truncated cone, with an angle sufficient to throw the rays under the specimen near the center, was placed around the cup, as shown by the dotted lines in the cut. In this instance, instead of diffused daylight, sunlight was reflected into the cone by means of a mirror. Some specimens gave good plates with this method of illumination, but the danger of over-exposing the cornea and sclerotic still remained, and an old difficulty reappeared, namely, the imperfections of the surface of the cup. But the increase in the obliquity of light brought out all the scratches on the surface of the cup, especially if a trifle over-exposed. This in turn was reduced to a minimum by cementing a perfect glass disc to the anterior surface of the cup by means of Canada balsam.

In working with direct sunlight, or the electric arc, it is important to remember that glycerin jelly becomes liquid at a temperature of 105 F.

In many instances the cornea is so transparent, and the sclerotic so white, as to require more contrast than is afforded by the porcelainized glass disc with which our mounts are sealed. This is met by supplying backgrounds made of colored papers such as black, pea-green, a rather dull canary, and neutral gray. Of these, the latter color was most useful. The canary-colored background works well in some cases where it is desirable to "hold back" the sclera, but it is liable to interfere with a transparent cornea.

Color screens have not given any useful results in Dr. Dixon's hands.

On the whole, the most satisfactory plates used were Corbutt's A and B, which require exposures varying from three to twenty-five minutes, depending on the quality of the light, size of stop and character of specimen, as in all other photography.

The method is still imperfect, as will be seen. No single method of illumination yet tried has answered for all specimens, and the color of some is such as to defy all efforts with or without color screens, with different colored backgrounds, with diffused daylight, direct sunlight, or the electric arc.

Other methods are in process of application, the most promising of which is an annular prism at the base of the cup with or without the use of the truncated cone.

TUMORS OF THE CONJUNCTIVA.

ILLUSTRATED BY THE PRESENT EXHIBIT OF MORBID GROWTHS.*

EDWARD ADAMS SHUMWAY, B.S., M.D.
PHILADELPHIA.

In response to the request of the Chairman of your Committee on Exhibit of Pathologic Preparations for a paper on some points in the pathology of the eye, as illustrated by our exhibit of the present year, it occurred to me that it would be well to confine myself within the limits of a comparatively narrow subject, and I have therefore attempted to make a résumé of our knowledge of tumors of the conjunctiva. With this aim in view I have obtained a number of preparations showing the various growths which are found on this membrane, and I desire at this time to express my thanks to the gentlemen who have assisted me by loaning sections and mounted specimens from their collections, especially to Drs. G. E. de Schweinitz, Clarence A. Veasey, William Campbell Posey and L. Webster Fox, of Philadelphia; John E. Weeks, Peter A. Callan, Wilbur Marple, Emil Gruening and Edgar S. Thomson, of New York; Dr. Flemming Carrow, of Ann Arbor, and Dr. Brown Pusey, of Chicago. Many of the cases have already been reported, and others will be published in detail at a later time.

The growths of the conjunctiva are of considerable interest, pathologically, because of their great variety, although they are, relatively speaking, infrequent, and constitute only a small proportion of the cases which we see clinically. The conjunctiva may be the primary seat of the growth, or it may be secondarily involved by extension from the neighboring tissues. I shall limit myself to those tumors which originate primarily in the conjunctiva. They may be divided into two main classes: (*a*) Malignant; (*b*) benign.

The malignant growths are represented by carcinoma and sarcoma. They appear clinically in very much the same forms and in patients usually beyond the fortieth year of life. Their point of predilection is at the corneo-scleral limbus, and it is often impossible to distinguish them, except by microscopic examination. The growth of carcinoma at the limbus has been said to correspond with its occurrence elsewhere in the body at the junction of epithelial surfaces of dissimilar structure. The difference at this point between the conjunctival and corneal epithelium is not marked, however, and the etiologic factor is rather the occurrence of true papillæ in the conjunctiva surrounding the limbus, varying from four to thirteen in number, which, as Nakagawa[1] has recently shown, become deeper in old people, and take on a sudden and enormous growth in beginning carcinoma. The carcinomatous growths appear first as small, pale reddish masses, which have but little tendency to spread inward, both cornea and sclera acting as very resistant checks; so they grow superficially, although rare cases have been described in which there was an inclination to extend inward from the start. In contrast to some of the benign epithelial growths, especially papillomas, they have no tendency to the formation of a pedicle, but possess a broad base, and are closely united to the underlying tissues.

The tumors consist of proliferating masses of epithelial cells, which develop directly from the surface epithelium and are separated into alveoli by a connective tissue stroma which is an extension of the connective tissue of the sclera and cornea. The behavior of the surface epithelium is at once a characteristic difference between carcinoma and sarcoma. In the former it is directly involved, while in the latter it passes smoothly over the surface of the growth, which raises it from the structures beneath as it extends. As a rule, carcinoma grows very slowly, but in some cases it forms large, fungous masses on the surface of the eyeball, the microscopic structure of which resembles papilloma very closely, and the examination of superficial portions of the tumor may lead to a very erroneous diagnosis. If allowed to remain, all of the carcinomas will ultimately perforate the eyeball, usually along the vessels and nerves at their point of penetration through the sclera. In

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks.

1. Nakagawa: Archiv f. Augenheilk., March, 1903.

some cases there is a distinct pigmentation of the stroma, so that a number of cases of melanocarcinoma of the corneoscleral limbus have been reported. Panas,[2] in fact, considered melanosarcoma to be the exception and melanocarcinoma to be the rule.

The question of malignancy is difficult to determine. The rapidity of growth may vary greatly; likewise the involvement of the cornea and sclera. Even superficial growths tend to recur, and while the extension by metastasis is rare, they should be thoroughly removed and the eyeball sacrificed, if it is evidently involved. Our collection shows a number of very good examples of carcinoma—some small and superficial, some showing tall fungous masses, and others extensive infiltration of the cornea and sclera.

SARCOMA.

Sarcoma, like carcinoma, occurs in individuals usually beyond middle life, and most frequently at the corneoscleral limbus. As a rule, the growths are pigmented, the pigment occurring both in the tumor cells, and in the connective tissue stroma, in which the cells are imbedded. As in the case of melanosarcomas of the skin, the conjunctival sarcomas develop chiefly from the pigmented nevi—the so-called pigment spots—on the conjunctiva, and, as Wintersteiner has shown, usually in the area corresponding to the palpebral opening, probably as the result of repeated slight traumatisms. The study of these pigmented nevi, or melanomas, is of importance, therefore, for the correct interpretation of some of the facts concerning sarcomas. Their structure corresponds closely to that of the skin nevi: circumscribed collections of large polygonal cells which are imbedded in a groundwork of subconjunctival tissue. The question as to the origin of these cells has been, and still is, a matter of dispute. On the skin Unna,[3] Kromayer[4] and others have held that they are derived from the surface epithelium, although the direct connection can not always be shown, while Ziegler[5] believes that they are due to the proliferation of the endothelial cells of the lymph vessels. Wintersteiner[6] was unable to find any confirmation of Unna's theory in so far as it related to the conjunctival nevi; on the other hand, as has been mentioned in speaking of carcinoma, Panas[7] long considered that these epibulbar growths were practically all carcinomas, although in a subsequent article he modified his claims and admitted that many were probably alveolar sarcomas, or endotheliomas, and thought that epitheliomas and sarcomas occurred together. In all of the nevi the epithelium is changed, often thinned, but many times it sends processes of cells downward into the tissue. These processes may be replaced by hollow, gland-like tubes, which may be so numerous as to give the growth a glandular or adenomatous appearance—nevus pigmentosus glandulosus. Cysts may often develop from the glandular formations, and may reach a large size and cause the nevus to atrophy by pressure—nevus pigmentosus cysticus. I have been able to secure several good cases of nevus of the conjunctiva, two of them cases studied by Wintersteiner and one loaned by Dr L Webster Fox, in which the overgrowth of the epithelium and the cyst formation are so marked as to overshadow the original growth of nevus.

From these pigment spots the sarcomas develop slowly into soft, vascular growths, which are usually more prominent than the carcinomas, and occasionally possess a pedicle. When they project over the surface of the cornea they are not ordinarily attached to it, but may be lifted away by means of a probe. Laterally, they are more firmly attached to the bulbar conjunctiva, but can usually be moved freely over the surface of the sclera. If they are not removed they continue to grow, and may reach a large size. In the majority of cases the cornea and sclera offer a remarkable resistance to invasion, and very few cases have been reported in which the tumor had invaded the interior of the eye. At times several nodules may appear at the limbus, or secondary nodules may spring up on the lids (Wadsworth and Verhoeff[8]). Recurrence after removal is very frequent, and may take place in the same position, or at a different portion of the limbus. They are commonly said to be less malignant than sarcomas occurring elsewhere, and Panas[7] makes a sharp distinction in this respect between the corneoscleral growths, which he terms "epibulbar," and those occurring at a distance from the limbus, which he calls "peribulbar." Verhoeff and Loring,[9] however, have shown that while the direct involvement of the eyeball is rare, there is a history of recurrence in 81.8 per cent. of the cases in which the patients were subsequently observed, local metastasis in 23 per cent., and general metastasis in 11 per cent. They therefore consider that epibulbar sarcomas are highly malignant, and believe the eyeball should be at once removed, if the patient's consent can be obtained.

Microscopically, the tumor consists of closely packed, spindle-shaped cells, running in definite bundles, or, more frequently, the cells are arranged in distinct alveoli, separated by a connective tissue stroma, and constitute the so-called alveolar sarcoma. In the latter case the cells may be spindle-shaped, but in many they show large, flat forms, which are epithelioid or endothelial in type. The growths are, however, to be distinguished from carcinomas by the absence of any involvement of the surface epithelium. These growths are well represented in the collection of this year. Some possess spindle-shaped cells; others show the epithelioid type.

Primary sarcoma of the conjunctiva of the lids is very rare, although the lid conjunctiva may be involved by implantation or recurrence of an epibulbar growth. Cases of lymphosarcoma of the plica semilunaris and of the fornix have been described as rarities. Lymphoma of the conjunctiva has been found in malignant lymphoma, with general involvement of the lymph glands of the body, and apparently as the first symptom in some instances. Very marked hypertrophy of the adenoid tissue of the conjunctiva, in the transition folds, with the formation of large tumor masses, which may cover the eye and make the opening of the lids difficult, occurs in the condition known as amyloid degeneration of the conjunctiva. Microscopic examination shows, in the beginning stages, great increase of the adenoid cells and the subsequent formation of amorphous masses, which in some instances give the reaction for amyloid, in others for hyaline. Dr. Weeks has loaned a slide which shows amyloid reaction on the surface of such a conjunctival growth, and I am able to exhibit a lymphosarcoma of the transition fold.

Carcinoma and sarcoma occur occasionally as primary growths on the caruncle, and show here much the same

characteristics as on the skin surface. Carcinoma has much greater tendency to form "pearly bodies" in this position than on the conjunctiva. A good case of primary carcinoma of the caruncle has been loaned by Dr. de Schweinitz,[10] and one of primary sarcoma by Dr. Veasey.[11]

The benign growths of the conjunctiva are either congenital or acquired. The congenital forms are sessile, while the acquired forms are usually polypoid in shape, and possess a pedicle. By far the most frequent of the congenital growths are the

DERMOID TUMORS.

Dermoid tumors form flat, dull white growths of firm consistency, usually situated at the corneoscleral junction, on the temporal side, and quite firmly attached to the cornea and sclera. The surface is often dry and may be covered with fine hairs, or, more rarely, with a few long hairs which irritate the eye by their presence. Microscopically, they represent small islands of skin. The epithelium is thickened, cutaneous in character, and covers a mass composed of dense connective tissue, in which hair bulbs, sebaceous glands and sweat glands may be imbedded. Frequently associated with other congenital anomalies, such as coloboma of the lid, they may take on a sudden, rapid growth in later life, and should be carefully removed. Most of the later writers assume a temporary attachment of the amnion to the eyeball during fetal life as the explanation of their origin. A number of such growths are included in the collection.

LIPOMA.

More rarely, subconjunctival lipomas occur beneath the bulbar conjunctiva. They appear as yellowish masses, situated generally in the outer angle of the eye, between the insertions of the external and superior rectus. Microscopically, they consist of lobules of fat, sometimes associated with considerable fibrous tissue. They frequently contain gland tissue, and as they are congenital, may be more properly termed dermolipomas. Some authors have contended that teratoid elements are always present, although they are easily overlooked. A number of cases, however, have been carefully studied in serial sections, and have proved to be pure lipomas. Occasionally they grow to a considerable size at puberty. They can be removed without difficulty, and show no tendency to recur. Two of these growths have been secured.

OSTEOMA.

As rare congenital tumors, about twelve cases of subconjunctival osteoma have been reported. These have been situated usually in the supero-external portion of the eyeball, which is also the position in which the lipomas are most frequently found. They represent small pieces of true osseous tissue, with lacunæ, bone corpuscles, etc., and are best explained as the result of a temporary adhesion of the amnion to the eyeball, and the subsequent development of bone in the tissue thus formed. They are illustrated by one specimen.

Lymphangiomas and telangiectasias have also been described as very rare congenital growths.

The acquired forms of benign growths are, in the majority of cases, polypoid in form. In the older textbooks all tumors of the conjunctiva which had a distinct pedicle were called polyps. Under this term, however, many different forms were included, and we now know that both soft and hard fibroma, adenoma, papilloma, granuloma, angiosarcoma, and even tubercular conditions, may assume a polypoid appearance, as a result, probably, of the constant movements of the eyelids. As Elschnig[12] states, true polyps, in the strict anatomic sense of the term, i. e., hyperplastic growths of circumscribed portions of the conjunctiva, which include all of its elements, such as are found in the nose, esophagus, intestines, etc., have never been described on the conjunctiva. The term polyp, however, is used by many writers to describe also the soft, edematous fibromas or fibromyxomas which occur in the nose, and although it would seem best, as Axenfeld[13] says, to drop the term altogether, if we are to use an anatomic classification, such good authorities as Fuchs[14] and Panas[2] make a separate class of polyps, and the name may be retained and used to designate the fibromas of the conjunctiva.

FIBROMA.

Fibromas are represented by two forms, soft and hard. The soft fibromas occur chiefly in the fornix, or in the palpebral conjunctiva, grow quite rapidly and possess long pedicles. They are composed of parallel bundles of spindle cells in a finely fibrillar tissue, and often contain many blood vessels. The presence of these vessels is the cause of a characteristic symptom that is often observed in connection with the soft fibromas, viz., severe bleeding on the slightest traumatism. Removal and cauterization of the base with nitrate of silver, or with the actual cautery, usually prevent any recurrence. Less frequent are the hard fibromas, which arise chiefly from the palpebral conjunctiva and from the caruncle. Their surface is smooth and covered with a thin layer of epithelium. The histologic structure is that of fibrous connective tissue, with comparatively few cells and blood vessels. They cause no inconvenience unless large, and when removed have no tendency to recur.

GRANULOMA.

Quite closely related to the soft fibromas are the granulomas which develop in places where a superficial loss of conjunctival tissue has existed, most frequently after tenotomies and enucleations, and also after rupture of chalazia on the internal surface of the lid. They are composed of naked masses of pure granulation tissue: closely packed polynuclear cells in a fine reticulum, which contain numerous capillary blood vessels. There is no epithelial covering, and the little growths may be snipped off, or, if left alone, will finally be constricted off by the contraction of the conjunctival tissue surrounding their base.

The fibromas must also be distinguished from the small growths on the tarsal conjunctiva and about the limbus in spring catarrh. These present themselves in the form of broad, flattened papillæ, which have been likened to paving stones, and while they can not strictly be included among tumors of the conjunctiva, as they occur in the course of an inflammatory process and disappear without leaving any trace, they nevertheless resemble the fibromas very closely in their histologic structure. They consist of dense fibrous connective tissue, the fibers of which may show a peculiar glassy degeneration, and are covered with a thickened layer of epithelium, which, especially in the circumcorneal growths, shows a marked tendency to send invaginating processes of cells into the depth of the tissue, so that the appearance is very similar to that found in cancroid.

Fibromas are represented by sections loaned by Drs. Weeks and Thomson. There are a number of sections of granuloma, and Drs. Posey and de Schweinitz have sent sections of tarsal growths in spring catarrh.

PAPILLOMA.

Another form of polypoid tumor of still greater importance is papilloma, or papillary fibroma. Elschnig,[12] in his very excellent article, stated that this was comparatively infrequent, but the subsequent papers by S. Fuchs,[15] Wagenmann,[16] Lagrange,[17] Zimmermann,[18] Grunert,[19] Kopetzky von Rechtperg[20] and others have shown that they are among the most common tumors of the conjunctiva. They form small growths, which may be distinguished clinically from the fibromas by the fact that their surface is not smooth, but is covered with tiny papillæ, like the surface of a raspberry. Frequently multiple, they occur chiefly in the neighborhood of the caruncle and semilunar fold, but also on the tarsal and bulbar conjunctiva, and unless removed very thoroughly show a decided tendency to recur. They are composed of branching papillæ of connective tissue, surrounded by thick mantles of epithelial cells, the preponderance of the epithelial cells showing that it is essentially an epithelial proliferation with which we have to deal. The connective tissue may be so little developed that the epithelial cells are found almost in contact with the walls of the capillary vessels. At times they are low and wart-like, at others they show long, villous processes and have a structure resembling a cluster of feathers. The latter appearance is well shown in two cases in the collection—one a case reported by Ayres of Cincinnati, and one obtained from Mr. Treacher Collins in London. When the papilloma originates on the caruncle, the surface epithelium partakes more of the character of skin epithelium, while on the conjunctiva it frequently contains numerous goblet cells. A number of very excellent specimens in the collection testify to the comparative frequency of the growth. The question as to their malignancy is often difficult to determine. When situated on the conjunctiva near the limbus they may be mistaken for an early stage of carcinoma, but on the other hand, while usually benign, they do unquestionably show at times a tendency to undergo carcinomatous degeneration and involve the tissues of the eyeball and lid, as cases by Horner,[21] Lagrange and Mazet,[22] Kopetzky von Rechtperg[20] and Risley and Shumway[23] have shown. Their removal should therefore be complete.

ADENOMA.

Adenomas occur occasionally on the eyeball, in the neighborhood of the caruncle, as pale red, isolated tumors, which may possess a pedicle or have a broad attachment. Only five cases have been reported, four of which have had their origin on the caruncle itself, arising from the tubular gland in this position, as in Veasey's[24] case, sections of which he has loaned, while Schirmer's[25] case on the semilunar fold probably developed from a misplaced gland, as there is normally no glandular tissue in this position. On the conjunctival surface of the lids, adenomas have been found originating in Krause's glands, at the border of the tarsal cartilage in the meibomian glands, and in the modified sweat glands of Moll. At times they show by their rapid growth and involvement of the surrounding structures that they are essentially malignant, or adenocarcinomas. The greater number of such cases originate in the meibomian glands, and show alveoli of large epithelial cells, which degenerate quickly and form large, poorly-staining masses in the center of the alveoli, as illustrated by two cases in the exhibit, one of which was loaned by Dr. Thomson of New York. Of course, these growths are not really conjunctival tumors, but since they may appear as tumors on the conjunctival surface of the lid, they must be mentioned for the purpose of differential diagnosis.

HEMANGIOMA.

Fifty-two cases of hemangioma have been collected by Pergens.[26] They consist of newly-formed capillary vessels, and should be sharply distinguished from varices and aneurisms. If they contain much fibrous tissue they may be termed angiofibromas, and are then closely related to the vascular fibromas. They may be congenital or develop in later life, and occur as primary growths on the palpebral conjunctiva, in the fornix, on the bulbar conjunctiva and plica semilunaris, as round, polypoid and occasionally sausage-shaped growths, the surface of which is sometimes smooth and sometimes nodular. They may remain stationary; at times they grow slowly, at others rapidly, without any apparent cause. When combined with sarcoma, the angiomatous formation is of secondary importance, and their course depends on the sarcomatous character of the tumor. Their histologic structure consists of twisted capillary vessels, which may also be dilated. If large blood cavities are present, we have cavernous angiomas, which are more rare. In their treatment the best results have been obtained by excision.

CYSTS.

Finally, as comparatively rare forms of new growths, we have the cysts of the conjunctiva. These develop in three chief places: on the bulbar conjunctiva, in the fornix and on the palpebral conjunctiva, in the form of transparent vesicles filled with a clear, serous fluid. Those of the bulbar conjunctiva represent usually small dilatations of the lymph vessels, and are hence lymphangiectasias or lymphangiomas. They occur in the neighborhood of the cornea, and are generally multiple, like strings of small, transparent pearls. Sometimes they communicate with each other, and more rarely they form isolated, yellowish cysts, which, however, remain comparatively small, and are thus to be differentiated from the cysts which originate in the conjunctival glands. Very rarely cysts on the bulbar conjunctiva develop from invaginated processes of epithelial cells. These processes, first described by Henle[27] and later by Iwanoff[28] as true glands of the conjunctiva, and known as Henle's glands, are now considered to be, as a rule, folds of the conjunctiva which are lined with epithelium. They are very frequent in chronic catarrh, and especially in trachoma. If the opening of these minute gland-like depressions becomes closed, there may be retention of the secretion from the cells and the formation of cysts. Cysts also originate in the head of the pterygia, by the same process of invagination of the surface epithelium, and subsequent isolation of the cells from the surface. A few cases have been reported of the introduction by

traumatism of epithelial portions of the skin, cilia, etc., beneath the conjunctiva and the formation of cysts from these included particles.

Cysts of the fornix may arise from the so-called Henle glands, and less frequently from the accessory lachrymal glands, or glands of Krause, in this position. The excretory ducts of these glands, forty-two or more in number, in the upper lid, and from two to six in the lower lid, may be closed by chronic inflammatory processes, and the retained secretion then widens out the ducts into cysts, which may reach considerable size, in contrast to the lymphatic cysts of the bulbar conjunctiva. When the cysts originate in Krause's glands some of the acini of the gland will usually be found in the neighborhood of the cyst, but this is not always the case, and as their size, position and contents are not diagnostic, the determination of their origin may be very difficult.

From these glandular cysts must be distinguished those due to the presence of the cysticercus. These occur in early life, and constitute, according to Ballaban's statistics, one-sixth of the number of cases of ocular cysticercus. They occur frequently as quite large, pale red, or more often whitish or yellowish vesicles, which are usually movable, but are occasionally attached firmly to the sclera, or to an eye muscle. If the wall of the cyst is thin, the embryo may be seen as a white spot within. Histologically, the wall of the cyst is composed of a thick connective tissue capsule lined with several layers of young cells, and the surrounding conjunctiva shows evidences of reaction due to the presence of the foreign body. Within the cyst wall is the characteristic cysticercus bladder projecting from one side. In the glandular cysts, on the other hand, the wall of the cyst is composed of a single, or at most, a double, layer of epithelial cells.

The cysts from the glands of Henle are quite frequent, both in the transition folds and in the palpebral conjunctiva in chronic catarrh, and in trachoma. They have been studied of late, especially by Fuchs[29] and Wintersteiner,[30] who have described concretions within the cysts, which arise either from the altered secretions of the cells lining the cyst walls, or from conglomerated masses of the dead cells themselves. Fuchs believes that in some cases the concrements are masses of actinomycetic threads. The collection contains the section of a large epithelial cyst of the upper fornix, one of subconjunctival cysticercus, and a very good example of cyst formation in old trachoma, with concrements within the cyst cavity.

Good Lay Advice to Young Physicians.—If your patients were all reasonable men and women, your task would be easy; but they are not. Even in their best estate they are not all reasonable men and women, and you will have to deal with them when they are not in their best estate, but are morbid. You will have to deal with patients who throw your medicine out of the window, and still expect you to cure them; in one house with a mother busy with other things and careless of the sick child; in another house with a mother whose weak and tearful sympathy does much to negative the influence of your presence and the effect of your medicines. It is not enough for you to know physiology and anatomy and therapeutics; not enough for you to know what your medical school has told you; you must know men and women—their physical constitutions, their mental and moral constitutions. You must understand them—their life, their narrownesses, their prejudices, their unreasonablenesses. You must see into them, that you may minister to them.—*The Outlook.*

PARAFFIN INJECTED SUBCUTANEOUSLY FOR THE CORRECTION OF NASAL AND OTHER DEFORMITIES.*

HARMON SMITH, M.D.
ASSISTANT SURGEON, MANHATTAN EYE AND EAR HOSPITAL.
NEW YORK.

HISTORY.

"To Dr. J. Leonard Corning of New York belongs the credit of first experimenting along the lines of subcutaneous injection of oils"; and, although applied to an entirely different purpose to that which paraffin is now devoted, yet of much import, since it was demonstrated that sterilized oils could be used subcutaneously, without resultant inflammation. Following this same idea, directed in a different channel, Gersuny of Vienna, in 1900, published an article stating that melted vaselin, when injected into a yielding tissue, forms a small tumor which remains *in situ,* causing no appreciable reaction. He used this method to overcome the deformity resulting from castration, blemishes due to cavities, depressed scars, and also for narrowing orifices.

Drs. Lynch and Heath appear to be the pioneers in America in the use of subcutaneous injection of paraffin for the correction of nasal deformities.

In 1901, I began a series of investigations on the cadaver to ascertain the action of paraffin beneath the skin. Before injecting the paraffin the temperature of the tissues was raised to 99 F., by hot applications, then I injected beneath the skin, on the dorsum of the nose, an amount of paraffin varying from a half to two drams, without exerting any restraining pressure on adjacent tissues. I found that small injections of the paraffin would remain *in situ,* and assume the conformity of the solid parts over which it was injected; but when the larger quantities were used, a portion would force its way into the soft tissues at the inner canthus of the eyes and along the course of the angular veins. This could be prevented by pressure over these areas. It was also demonstrated that an intimate adherence exists between the skin and the lateral cartilages at the tip of the nose, and hence was noted the importance of liberating the tissues between the skin and cartilages at this point before injecting the paraffin in the living subject. Later I injected melted paraffin into the back, ears and nose of a rabbit, without anesthesia, and with slight apparent pain to the animal. Ten days later, the examination of the tissues around the injected paraffin gave no evidence of acute inflammation. There had been some attempt on the part of the tissues to encapsulate the injected mass, but the paraffin itself had undergone no obvious change. Later another injection was made into the peritoneal cavity of a rabbit, and after a 22 days' period the animal was killed. Here no evidence of inflammation was present—not even the formation of adhesions. The mass had moved about the peritoneal cavity and become rounded in shape, and had finally lodged between the liver and diaphragm. From this I concluded that paraffin must be inert if injected into the tissues under proper surgical precautions. The paraffin used in these cases melted at 110 F.

Dr. A. E. Comstock[1] of St. Paul, Minn., has described the results of his experiments with rabbits along the pathologic line of injected paraffin. He demonstrated the changes in the tissue after injections varying from

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. George L. Richards, O. Joachim and G. V. Woollen.

1. On Paraffin, New York Medical Record, Nov. 1, 1902.

2 to 16 weeks, having used paraffin with melting points from 102 to 112 F. In all cases where paraffin was used with a melting point of 102 F., the animal died within 2 weeks from thrombosis. The best results were obtained with paraffin with the higher melting points. From his very careful investigations, he finds that the harder paraffins are not truly encapsulated in the tissues, but become a part of the new tissue. This theory is further borne out by Walker Downie, who injected paraffin into a carcinomatous breast which was subsequently removed, and microscopic sections made and examined.

DEFORMITIES MOST FREQUENTLY PRESENTED FOR CORRECTION BY INJECTION OF PARAFFIN.

1. Saddleback noses.
2. Depressed scars from mastoid operations.
3. Depressed scars from frontal sinus operations.
4. Depressed scars from traumatic injuries.
5. Smallpox pits.

The saddleback nose occupies the most prominent place in this category, and is the one toward which our attention, as specialists, is most generally directed. The causes of saddleback noses may be mentioned in the following order of frequency, according to my experience: 1, Traumatism; 2, syphilis; 3, heredity; 4, abscess; 5, lupus; 6, scrofula.

At least 50 per cent. of my cases have been caused by traumatism.

ADVANTAGES AND DANGERS.

The advantages to be gained by subcutaneous injection of paraffin over any surgical procedure are:

1. The deformity is corrected without a resulting scar, provided no slough or abscess follows, which is a sequence of surgical uncleanliness or hyperinjection.

2. A 2 to 4 per cent. solution of cocain is all the anesthetic necessary, and completely overcomes the pain of inserting the needle, which is all that attends the operation.

3. The slight reaction following the injection is temporary, and the patient may resume his daily pursuits in 12 hours.

4. The results, when proper care has been exercised, are pleasing alike to patient and operator.

The possible dangers that may result are:

1. Abscess or slough, due to either infection or hyperinjection.

2. Embolism.

3. Deformity from hyperinjection.

The first may be obviated by surgical care, and proper attention to the quantity of paraffin injected, so as not to cut off the blood supply to that area.

Embolism is avoided by injecting the paraffin in a semisolid form, and deformity from hyperinjection is entirely under the control of the operator when using a syringe operated by screw force. This last danger is the only one ever coming under my personal observation, and it resulted then from using a piston syringe.

INSTRUMENTS DEVISED FOR INJECTION.

When the injections of paraffin were begun, it was a far more difficult matter to accomplish the desired result than at present. The most potent difficulty was in the syringe. An ordinary serum syringe or an aspirating syringe was all the armamentarium at hand, and the rapidity of action necessary before the hardening of the paraffin in the needle took place, was sometimes detrimental to a good result. This objection was soon obvious, and experiments were made on a syringe which would relieve the necessity for haste. As the dangers of emboli had been harped on by many, I undertook to devise a syringe by which paraffin could be injected in a semisolid form, and to put at rest all the accusations against the advisability of injecting liquid paraffin into the tissues. After a time I succeeded in designing one that would eject paraffin from its needle in a semisolid form, and without the necessity for haste. The syringe which I have devised and here present is thus described: It consists of a metal barrel of 90 minims capacity, and is constructed with a large diameter and short axis, so that dexterity in its manipulation will not be lost by the distance of the hand introducing the needle from the point of introduction. The needle is also short for the same reason, and is just larger than a hypodermic needle. The piston and all other parts being of metal, obviates the necessity of washers, and thereby renders it more capable of sterilization, lessening the danger of sepsis. The piston rod is graduated in minims, and is surrounded by a course screw worm. Fitted on this rod is a metal thumb screw, which runs up and down, and is made to screw into the upper end of the cylinder at the volition of the operator. When this thumb screw is not fitted into the cylinder the piston works up and down as in any other syringe, and any liquid can be drawn up and expelled readily by manipulation of the piston; but when the thumb screw is put into place, it becomes necessary then to screw the piston down, and by so doing the paraffin is slowly ejected from the needle. When the paraffin is semisolid, it winds out

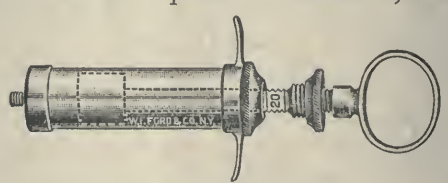

Fig. 1.—The author's syringe.

from the needle in a thin cylindrical thread, but with sufficient force to uplift any tissues not held down by fibrous adhesions. In performing the injection slowly, in this way, ample time is allowed for molding and smoothing the injected paraffin, and the danger of hyperinjection is minimized. The simple mechanical devise which renders the syringe so effective places it at the disposal of any operator, and renders it both portable and free from arrangement other than sterilization.

PARAFFIN EMPLOYED AND ITS METHOD OF PREPARATION.

In my experience, the best results follow the use of a paraffin with a melting point of 110 F. This is not a pure paraffin, but is a mechanical mixture of commercial paraffin, melting at about 120 F., and the addition of petroleum jelly sufficient to bring the melting point down to 110 F. This quantity has to be estimated somewhat carefully, and can not be stated in definite proportions. I have found that while one corner of a plate of paraffin will melt at 120 F., the other will melt at 140 F., so that in having it prepared for use, the chemist makes up a large quantity each time. The melting point must be accurately determined. Test tubes of one-half ounce capacity are filled with the liquid substance, sealed with wax and placed on a sand bath where the temperature is raised to 300 F., thus insuring sterilization.

PREPARATION OF FIELD OF OPERATION AND INSTRUMENTS.

Ordinary surgical technic is all that is to be observed; my routine at the Manhattan Eye and Ear Hospital,

where I have performed most of the operations, and at the office, has been as follows:

1. Scrub the field of operation with green soap and water.
2. Apply alcohol freely.
3. Wipe off with bichlorid solution of 1 to 5000.
4. Pour on a little ether.

The syringe and needle are boiled and then allowed to cool sufficiently for easy manipulation, and the hands are surgically cleansed. At the point of entrance of the needle I usually inject into the epithelial layer of the skin only three to four minims of a 4 per cent. solution of cocain. I believe this does no harm to the tissues, nor is it misleading as to the quantity of paraffin necessary to overcome the deformity, if the solution is just at the point of the needle's entrance into the skin and not beneath it. Some operators prefer a weaker solution. I have in several instances injected the paraffin without any anesthetic, and with but slight pain to the patient, and that only on entrance of the needle. Paget and Walker Downie both use a general anesthetic; but, to my mind, this adds an unnecessary element of danger far greater than the operation itself. To insure still further the sterilization of the paraffin, I have devised a tin receptacle supported on an attached tripod, which raises the bottom an inch from any plane surface on which placed, and closed with a detachable lid. This

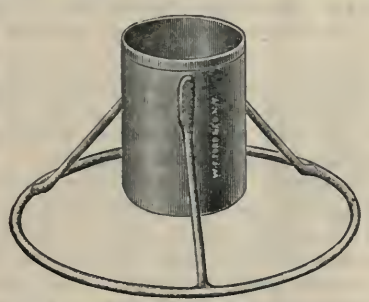

Fig. 2.—The paraffin sterilizer.

arrangement prevents the paraffin from burning and browning. Into this I pour the paraffin, from the test tube, after melting, and place this receptacle into a sterilizer, or any ordinary boiler—surround it almost entirely with water and boil. After I have boiled it for a few minutes, I remove the receptacle and permit it to cool until the paraffin therein is about 120 F. I then draw it up into the syringe which has been sterilized in the same boiler with the paraffin. When sufficient is withdrawn, I evacuate the air bubbles from the syringe by pressing the piston upward, and run my set screw into place. Some two or three minutes are now allowed for the paraffin to assume equal consistency throughout and to cool down to a semisolid state. This may be expedited by placing the syringe in a bowl of sterilized water at 80 F.

Before beginning my injection, I warm the needle of the syringe in some hot sterilized, or even boiling, water, to soften the paraffin which has formed a hard plug in it. This prevents the paraffin from running back of the metal piston, or, as happened in one instance brought to my notice, bursting the needle, when too great force is exerted by means of the screw attachment. Should the paraffin come out in little interrupted spurts of a too liquid nature when the piston rod is revolved, I again cool, warm the needle as before, and continue this routine until the paraffin is ejected in a thin cylindrical thread, easily moldable, and quite impossible of forming an embolus. When the paraffin reaches this consistency it may be kept many hours ready for use, at the temperature of the room, if only the precaution to warm the needle is taken each time before attempting the injection. When this condition is reached, I insert the needle beneath the skin, but above the periosteum, carrying its point slightly beyond the deformity and begin to inject; having the assistant exercise pressure on the soft tissues at inner canthi and on the region of soft tissue at the junction of the nose and forehead. Supporting the syringe with one hand, I mold and smooth the injected paraffin to the requirements of the case, only injecting small quantities at a time, and exercising the greatest care to prevent injecting too much.

In most cases I overcome the deformity at the first injection, but it is by no means advocated, as a rule, and some of the best results have followed three injections. After the first few minims have been injected, I gradually withdraw the needle, making slight additions to the original quantity, and taking every care to mold and smooth the surface, so as to leave the overlying tissues perfectly even.

After withdrawing the needle, I spray the part with ether, which almost immediately hardens the paraffin and insures a better result. The point of entrance of the needle is sealed with collodion and the patient instructed to apply ice cloths for twelve to twenty-four hours. A slight redness generally ensues, somewhat commensurate—in inverse ratio—with the faithfulness with which ice cloths have been kept on. This redness has lasted for a week or ten days in some of my cases, but eventually all disappeared under the application of a 25 per cent. solution of ichthyol.

When the second injection is necessary, I have the patient return in one week, but where circumstances make earlier attention desirable I have not hesitated to make it in three days after the first. The quantity requisite for correcting even a most marked deformity is very small. A dram of paraffin under the skin produces a most astonishing effect, and I believe that, in most instances, a small fraction of a dram is all that is requisite for overcoming ordinary deformities. Since using my syringe, where it can be accurately ascertained just how much is injected, my computations have materially diminished, and I find fifteen to thirty minims is the average amount of injection. Gersuny once injected two ounces in the correction of a deformity of the chest, which represents the maximum amount yet reported. Jukuff found in animals that unpleasant and fatal results occurred only when one-tenth of the bodily weight was used, and in cases where the melting point was below the bodily temperature. From this we may conclude that at present there is no danger to life in the correction of any known deformity. The results obtained are uniformly good, with here and there an unfortunate necrosis, a hyperinjection, or a misplacement, which complications can all be avoided.

CAUSES OF NECROSIS.

1. Surgical uncleanliness.
2. Too much pressure, cutting off blood supply to the part.
3. Injection into the skin and not beneath it.
4. Constitutional disease of patient, as diabetes or Bright's disease.

The hyperinjection may be avoided by the use of syringe, as described, where absolute control of every minim is under the guidance of the operator, and by a little conservatism in attempting to correct the entire deformity at one sitting. The misplacement or lodge-

ment in neighboring parts not intended for the injection, is again the result of a piston syringe, where the needle becomes plugged with paraffin harder than that in the syringe, and on exerting more force this is violently ejected and followed by a volume of liquid paraffin which shoots everywhere beneath the skin and is beyond the control of the assistant or any mechanical device. The most humiliating result is one from hyperinjection or misplacement. The chemical agent that will dissolve out an overplus of paraffin through the skin is not yet within our ken. I have not only been consulted by many unfortunates from other operators' hands, but had a similar result from the use of an aspirating syringe in one of my own cases. An attempt to curette this overplus away through a subcutaneous opening was far from successful. Since then I have obtained better results by cutting away the loose tissue in which the paraffin was imbedded. In one case sent me for correction this method was entirely satisfactory. Here the paraffin had even extended into the soft tissues of the upper eyelid, and its removal occasioned considerable tumefaction, lasting some days. I have never observed any absorption to have taken place in any of my cases, and it has now been two years since the first were begun. No unusual sensations occur over the injected part, except that of numbness immediately following the injection.

Paraffin has been largely employed abroad in filling in the excess of nasal space resulting from atrophic rhinitis. I can not advocate this until further demonstration proves its utility.

SOME OTHER SURGICAL USES OF PARAFFIN.

1. To overcome incontinence of urine.
2. To diminish size of hernial openings.
3. To replace testicles.
4. To cover stumps of amputated bones, preventing wear through flaps.
5. To prevent adhesions in ankylosed joints after first breaking them up.
6. To form plate in trephined skull, preventing dura from adhering.
7. To fill in malformations around neck and in attenuated mammæ.

CASE 1.—W. J. H. No specific history. Injury due to horse's kick when a boy. The nasal bones fractured, septum crumpled and bridge entirely flattened, so that the area between the eyes was entirely flat. In addition a heavy scar ran transversely across this space, from the distal extremity of the right nasal bone to the inner canthus of the left eye. I hesitated at first to attempt operating, but finally decided to do so—aiding the operation by loosening the scar tissue with a spear-headed paracentesis knife subcutaneously inserted. The entrance was perfected under cocain near the tip of the nose, and then carried beneath the skin to the binding scar tissue which I liberated in small quantities. At the same point of entrance I inserted the paraffin needle and followed the line of incision. I raised the tissues quite perceptibly, and no unfavorable results obtained.

Two weeks later I began the same performance, making entrance over the nasal spine. This likewise resulted favorably. A good part of the deformity was now overcome, but I concluded to perfect the operation by a third injection. This time I went in at a point midway between the inner canthus of the left eye and my second incision. In liberating the scar tissue this time I cut too close to the surface, and when I injected the paraffin I noticed the white fibrous tissue was considerably stretched. A few days later the paraffin had worn through a small opening, and the most of the last injection worked out; but either sufficient remained, or new tissue formed to overcome the deformity to the satisfaction of the patient, so that I have not attempted further interference.

CASE 2.—Injury traumatic, operation Oct. 30, 1902. Cocain anesthesia. One injection only was made. Method pursued same as that advocated in paper. Result entirely satisfactory.

44 West Forty-ninth street.

DISCUSSION.

DR. O. JOACHIM, New Orleans—I can support the statements at the end of the paper. In my experience, which is not as large as the Doctor's, I have met the difficulties cited by him in the use of the plain piston syringe. I have seen a case in which there is an objectionable amount of paraffin lodged in the space the Doctor pointed out above the nasal bones. It was due to the paraffin becoming hard and in injecting with some force to overcome the obstructing mass too much was injected. I shall take it out later surgically. The study of this subject has shown that the paraffin of higher melting point becomes encapsulated and the softer paraffin of lower melting point becomes permeated by fibrous tissue. The paraffin I use melts at 104 to 106 degrees. The procedure is a simple one, and to those with a surgical inclination there should be no difficulty in overcoming any abnormality in the shape of the nose or depressed scar after a mastoid operation or after a frontal sinus operation.

DR. J. F. BARNHILL, Indianapolis—Dr. Smith spoke of instances in which injections over the cartilages need to take place and referred to dissecting the cartilage from the skin. I should like to ask the method of doing this. I should think the same thing would be necessary when injecting under scar tissue.

DR. HARMON SMITH—At the tip of the nose, where the skin is adherent, I simply swing the point of the needle around under the skin. In other cases it may be necessary to use a small tenotomy knife to relieve the adhesions.

DR. ROBERT C. MYLES, New York—Those of us who have used the old syringe have had great difficulty in controlling the injections when the paraffin was in a more or less liquid state. My cases have been troubled more with redness of the nose than his seem to have been. He takes it away with ichthyol, but I have not always been so fortunate. I had one man develop red streaks. The pressure of the paraffin on the veins and arteries seems to obstruct them and they become more or less enlarged.

DR. C. M. COBB, Boston—One point that the essayist simply alluded to is the fact that sometimes the skin turns white during the process of the injection. It has alarmed me to see the skin become markedly pale and I have stopped the injection and massaged the skin and then done nothing more for a few weeks. I had one patient with a very satisfactory result, except that the nose was somewhat red. That was more than a year ago and it is somewhat red yet. Peroxid of hydrogen relieves the redness temporarily. Alcohol did him no good. The mixture of clay, bismuth, etc., put on the market under various names, put on at night, did some good.

DR. E. FLETCHER INGALS, Chicago—Would it not be possible to melt the paraffin after injection without injury to the skin? I do not know the highest temperature the skin will tolerate, but I do know it will tolerate at least 113 F., possibly more. I should like to know what temperature could be safely borne. If this could be done we might melt the paraffin and withdraw any excess by an aspirating syringe.

DR. HARMON SMITH, New York—As to what Dr. Myles has said regarding the photographs, there are mistakes made both ways. You never get a picture that looks as bad as the patient before, nor one that looks as good as the patient when it is done. When you ask for an absolute profile, frequently the photographer will give you a three-quarters. The same thing is largely true of the size of the picture. Redness is present in a good many cases. I have seen a case in which the redness lasted over a year, but it gradually disappeared. There seems to be a tendency on the part of Nature to take care of a foreign body, and I think the reinforcement of connective tissue that grows into this mass requires an increased

blood supply, and later, when the blood supply is no longer necessary, the redness will disappear. As to the furnace worker, I think if the man would remain away from his work for, say a week or two, he could then go back without danger of shifting the paraffin. Although it might be made soft and doughy by excessive heat, it would not shift. I do not think the heat would extend far down into the subcutaneous tissue, as body temperature remains the same regardless of external temperatures. Dr. Cobb has spoken of the white appearance that results from getting too much paraffin in. I invariably stop when I see the tissues becoming white, for I think then I am near the danger line. There is then considerable pressure, which is often due to not liberating the adhesions sufficiently. Beware of hyperinjection. Take time and you will have little trouble.

Dr. Ingals has spoken of the possibility of aspirating the paraffin, when for any reason it is desirable to remove it, after first melting it while in the tissues. I have tried almost every method for removal. In one case the patient had tried to iron it out and had failed. In another case, which had been injected by another physician, numerous injections had been made in an attempt to relieve the deformity resulting from atrophy of the muscles of the face, with the result that a number of little balls of paraffin remained under the skin. I tried to iron it out, but without marked success. In this same case, where there was some paraffin escaping from a small opening in the skin, I tried to iron it out, but was only partially successful. However, in this case some time had elapsed since injections were made. I did succeed in smoothing the surface somewhat.

THE SUBCUTANEOUS INJECTION OF PARAFFIN FOR THE CORRECTION OF DEFORMITIES OF THE NOSE.

F. GREGORY CONNELL, M.D.
SURGEON TO ST. VINCENT'S HOSPITAL.
LEADVILLE, COLO.

(*Concluded from page 703.*)

INSTRUMENTS.

The instruments necessary for the proper performance of this operation are very simple and very few.

A special receptacle for the paraffin, as described by Smith, while convenient, is not essential.

The syringe is the all-important consideration; an all-metal syringe is to be preferred because of the ease with which it may be absolutely sterilized by boiling. One with the screw worm on the piston rod, and on this the thumb screw that can be attached to the barrel of the syringe, is almost invaluable. The size of the syringe is not so very important; that it be not ungainly in the handling is about the only practical limitation. Smith and many others use one with a capacity of about 90 minims, while Downie employs one that will hold 10 c.c. (2.5 3).

The needle should be short and but a little larger in diameter and lumen than is the ordinary hypodermic needle.

TECHNIC.

As regards the technic, that of Gersuny has not been modified to any considerable extent. With the exception of the special syringes, the instruments are practically the same. The operation may usually be carried out in the following order: 1, preparation; 2, anesthetic; 3, introduction of the paraffin, and 4, after-treatment.

1. *Preparation.*—The most careful and painstaking antiseptic precautions must be observed. The skin of the nose, cheeks, forehead and chin must be given a thorough scrubbing with soap and water twenty-four hours before the time set for the operation, or better, once forty-eight hours, and then again twenty-four hours before the time set for the injection. The night before a moist dressing should be applied over the proposed site of injection, over this oiled silk, and then a bandage to keep it in place.

Immediately before the operation, with the patient on the table, the skin of the nose and face should be once more cleansed. The patient's head and hair should be covered with a sterile cap and the remainder of the body with a sterile sheet. The operator's and assistant's hands are being rendered surgically clean while the instruments are being boiled and the paraffin is being again sterilized.

2. *Anesthetic.*—A general anesthetic is never absolutely necessary. A local anesthetization of the skin, at the site of the entrance of the needle, is all that is necessary in the great majority of cases. There is a diversity of opinion regarding the use of a general or a local anesthetic in this class of cases. Downie says:

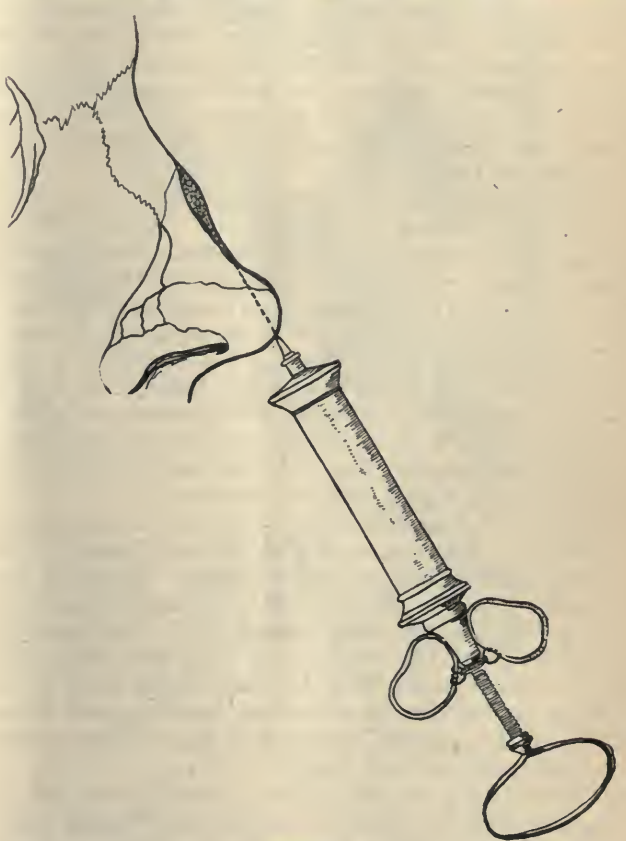

Figure 1.

"The patient may or may not be anesthetized. In many cases there is a distinct advantage in having the patient under an anesthetic. A local anesthetic is, in my opinion, inadvisable."

On the other hand, there is certainly a distinct advantage in having the patient not under general anesthesia, and in certain cases the use of a local anesthetic is the only way that this is possible. While the dangers of general anesthesia are very small, they are, nevertheless, constantly with us and must be considered. The location of the intended insertion of the needle for the injection of the paraffin can be easily anesthetized with a solution of cocain or eucain B., the strength of the solution varying from 1 to 4 per cent., according to different authorities. A 1 per cent. solution was used in all cases by the writer.

Freezing with ethyl chlorid of the site of the future needle puncture may be employed as a preliminary step

before the injection of the cocain or as the only local anesthetic, dispensing with the cocain entirely.

In some cases, the injection of the paraffin has been made without any preliminary anesthesia of any kind, either general or local. But the anesthetization of the skin, at the site of the puncture, is advisable, in order to prevent any sudden movement or jerking of the head at the time of the needle prick, which might be the cause of more or less serious damage or inconvenience.

3. *Introduction of the Paraffin.*—The paraffin, having been boiled with the instruments, is now in the fluid state, and is drawn into the syringe—the barrel of the syringe had best be about three-quarters filled. With the ordinary syringe considerable haste is now required in order to make the injection before the paraffin will solidify in the needle of the syringe, so causing great difficulty and force in its removal, and with the probability of irregularities in the mass because of the unevenness of the force applied during the injection. However, with a syringe such as has been described by Smith and by Freeman, this haste is not necessary, the force being applied by means of the screw arrangement, and the result is always even and satisfactory, no matter how long a time may have elapsed between the filling and the emptying of the syringe.

The air being expelled from the syringe, all is ready for the introduction of the paraffin. The skin of the nose is picked up in a fold, and the needle then inserted under the skin. It has been recommended that the skin be incised with a small scalpel, as a preliminary step, and then followed by the insertion of the needle, in this way hoping to decrease the pain and the resistance to the passage of the needle. The site of entrance of the needle should be away from the region of the greatest deformity. If a saddle-back nose, the needle is usually made to enter the skin at about the junction of the nose with the forehead, about on a level with the eyebrows.

Leonard Freeman, and the writer in his cases, have inserted the needle at the tip of the nose, instead of at the apparently more common situation. The chief advantage of this locality over the one more commonly used is that it allows more freedom in the manipulation of the point of the needle after it is once under the skin. Freeman says: "The thickened tissues at the tip of the nose prevents the paraffin from diffusing itself along the track of the needle, as is apt to occur in the areolar tissue at the base of the nose."

From either point, the needle is carried along subcutaneously until its extremity is at the most distant point of the deformity, and is then gradually withdrawn, leaving its deposit of paraffin as it recedes (Fig. 1). In this way all parts of the deformity may be reached with but the single puncture of the skin. The remote point of entrance is to prevent, in a way, the escape of the paraffin after the withdrawal of the needle. As the paraffin escapes into the cavity of the defect, the needle is slowly withdrawn, and with the finger of the left hand the operator molds and outlines the freshly deposited paraffin, thus preventing the injection of too large an amount, also preventing its extension into regions where it is not desired, and likewise preventing the occurrence of any lumps or irregularities in the artificial body. A little finger inserted into the nostril will prevent an encroachment on the lumen of the nasal canal.

The needle should be well withdrawn by the time the deformity has been fully corrected, after which the needle is removed through normal skin, in which it leaves no paraffin and the puncture sealed with a collodion and cotton dressing.

It has been recommended that the entire defect be not remedied at one injection. This is especially good advice when the tissue to be injected is dense and inelastic. Rather inject too little than too large an amount.

4. *After Treatment.*—If the injection has been made into loose tissue, the paraffin must be kept quiet and free from pressure, otherwise it may migrate into the surrounding structures. Under such circumstances, iced cloths may be applied to the region in an effort to make the paraffin set more rapidly. Sometimes there may be for, perhaps, the first twelve hours after the operation a marked disturbance in the local circulation, as is evidenced by great redness and swelling and, more rarely, pain in the tissues about the eyes and nose. This transitory reaction may also be relieved by the application of cold compresses.

Figure 2.

Paget gives his patients a hand glass as soon as they come out from under the general anesthetic and allows them to mold the nose at that time.

After the first twelve hours the swelling, the redness and the pain rapidly diminish, if they have not already gone, and, as a general rule, no further treatment is required.

REPORT OF CASES.

CASE 1.—Mrs. F., American, widow, aged 42. When a small child was struck in the face with a sharp ax, which resulted in a severe injury to the nose, the nasal bones were broken and followed by a necrosis, which caused a loss of the entire septum, a depression of the nasal bridge and collapse of one nostril.

Examination revealed on a profile view (Fig. 2): 1. A typical saddle-back nose. The extent of this depression, or sinking in of the bridge of the nose, was about one-sixteenth of an inch below the normal line of the nose, the greatest depression being situated at about the junction of the nasal bones with the lateral cartilages of the nose. 2. The tip of the nose was forced upward; this feature was exaggerated by the depression immediately above it. 3. A still more unsightly deformity consisted of a ridge or strip of flesh extending from about the junction of the middle with the superior third of the upper lip to the internal aspect of the tip of the nose. The attachment of this strip at the labial extremity was considerably below the cleavage of the lip and the nose proper, in consequence of this low origin daylight could be seen between the superior margin of this strip and the inferior margin of the nose proper. This artificial column was about half an inch in diameter at the labial insertion, and from that tapered down to about a quarter of an inch at the nasal end.

This objectionable strip of tissue was the result of a previous operation, the object of which was to supply the nose with an

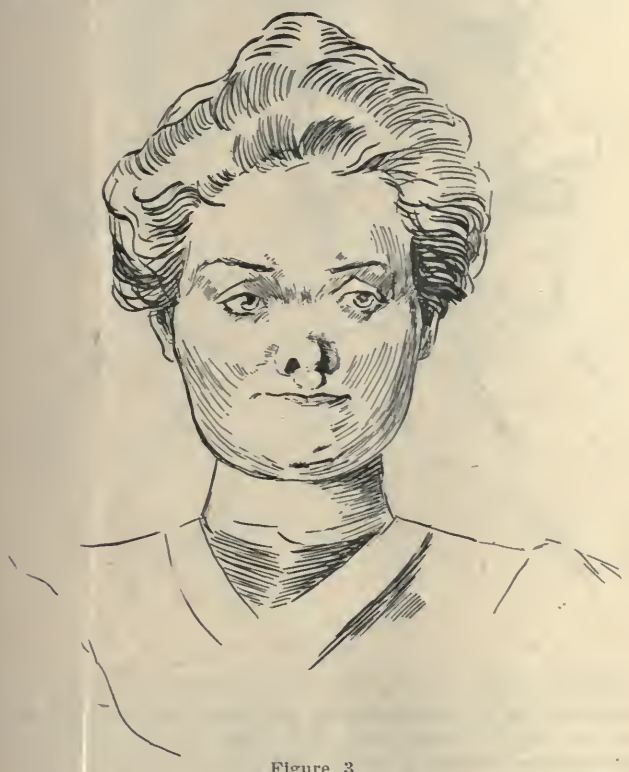

Figure 3.

artificial column, and so to divide the single anterior nares into two, and in this way decrease to some extent, at least, the deformity. In this operation a flap was dissected from the median line of the upper lip, turned on itself and attached to the internal surface of the tip of the nose. This flap healed in place nicely, but it was too large and bulky at the lip, and was attached to the lip at a point too low down, so allowing a space between the new column and the inferior margin of the nose proper.

This operative procedure for the formation of a new columna nasi was first described by John B. Roberts, in the Mutter Lecture of the College of Physicians of Philadelphia, 1900, entitled "The Surgical Treatment of Congenital and Pathologic Disfigurements of the Face." (*Phil. Med. Jour.*, June 23, 1900, p. 1425.) Yet, despite such a prominent publication and as an example of the disregard of American writings by some of the European writers, we find in the *Medizinskoie Obozrenie*, Vol. lviii, No. 15, an article by P. I. Kusmin, entitled "A New Method of Correcting the Destroyed Nasal Septum," which is practically the same method as has been recommended by Roberts and employed in this case.

In this instance the result is unsatisfactory, in that the base of the flap took its origin too far away from the junction of the nose and the lip. This fault was corrected by subsequent operations, but as no paraffin was injected they will not be considered under this title.

On a front view of the face (Fig. 3) the most noticeable departure from the usual was a collapse of the right nostril. That portion of the nose usually held in proper position by the inferior lateral cartilages was flattened and almost in contact with the median line. There being no septum the interference with respiration, especially inspiration, was not marked. The patient usually wore a metal, aluminum, intranasal support, in this way almost correctly remedying the defect. The wearing of this support was irritating, annoying

Figure 4.

and objectionable. The new column was very prominent and bulky at its origin from the upper lip, and appeared as a reddish bunch on the lip. The depression in the bridge of the nose was not so noticeable as in the profile view. The tip of the nose seemed to be tilted upward and the anterior nares seemed to present in an anterior inferior direction, instead of in an inferior direction, as they should normally. On an intranasal examination, there was noted most prominently the absence of a septum. The mucosa lining the cavity appeared to be normal.

The patient came requesting that her nose be improved on; that the artificial septum be raised at its labial extremity so that it might appear continuous with the nose on profile; that the sinking in of the right ala might be remedied so that it would not be necessary for her to wear the intranasal support, and that the depression in the bridge of the nose might be rendered less conspicuous, if not removed.

All these conditions were in time corrected, but, in accordance with the title, this paper will deal only with a consideration of those operations in which paraffin was injected as a prosthetic measure.

Operation 4, Injection 1.—A typical operation for the repair of a saddle-back nose: Cocain, 1 per cent. solution, was employed as the anesthetic. The needle was made to enter the skin at a point near the tip of the nose, and about twenty drops of the paraffin were injected. There was no pain during or soon after the operation; the next day and the day following there was noted a sense of fulness and some uneasiness, but at no time was there any complaint of sensation coming under the heading of pain, in its proper sense.

The second day after the operation there was noticed a slight redness of the skin over the injected paraffin, this increased for about a day and was then pronouncedly red.

This redness remained stationary for about a month, and since then has very gradually decreased, so gradually, in fact, that there is still a distinct reddened area over the bridge of the nose. On pressure this redness will disappear, but returns immediately after the removal of the pressure. A few dilated and tortuous capillaries course their way over this area. The condition is still present fourteen months after the injection. There has been practically no change or decrease

Figure 5.

Figure 6.

in the redness during the last six or seven months, it is not as marked as it was during the first few months, but still requires the profuse application of face powder in order to prevent her nose from being conspicuously red.

There is absolutely no pain, tenderness or abnormal sensation over the injected portion, or any other portion of the nose or face. With the exception of the redness the operation is quite satisfactory in its outcome, both to patient and surgeon; another small injection is needed to make the result perfect (Fig. 4). The obliteration of the dilated blood vessels by means of electricity or by crucial incision of the skin is now under consideration.

Operation 6, Injection 2.—A second injection was made in the same case two months after the first in an attempt to remedy the collapse or flattening of the right wing of the nose. In reviewing the literature on this subject, very meager as it is, no practical method with anything but a remote promise of success seemed to present itself.

Roe advocates in such cases that we incise the lower shield cartilage, and sometimes the upper shield cartilage also, sufficiently to overcome their elasticity, and then to hold the alæ, with their incised cartilages, in the more expanded position, until repair takes place, and the tissues are fixed in their new shape and form. He also recites a case in which the cartilage is dissected subcutaneously and "reset" in its proper, or at least in a better, location.

Such maneuvers in this case were out of the question, as there was no cartilaginous tissue in the ala of the nose on the right side.

The more radical method advocated by Fritz Koenig (*Berl. Klin. Woch.*, Feb. 17, 1902) of replacing the abnormal or diseased ala by a portion of the entire structure of the auricle and suturing this in place on the nose, seemed a trifle too radical for any condition in which there was not an absence of the ala. But no other method of replacing the missing cartilage seemed available. At this time the idea of producing artificial cartilage presented itself and was grasped as a most satisfactory solution to the rather trying problem.

Accordingly the ala was injected with paraffin as follows: After a careful and proper cleansing of the skin and mucous membrane of the nose a preliminary anesthesia, Schleich's solution No. 1, was injected into the site of the proposed par-

Figure 7.

affin injections. After a lapse of about twenty minutes the needle of the syringe containing the paraffin was inserted into the free edge of the ala at a point about half way between the tip of the nose and the cheek. The needle was made to penetrate about three-eighths of an inch, and then about six drops were injected. The needle was withdrawn and the puncture sealed with collodion.

The needle was now introduced at a point three-quarters of an inch above the free border of the ala, in about the center of the lateral aspect of the nose from above downward, for a distance of about a quarter of an inch, and the same amount of paraffin injected.

The intranasal support was now introduced and held the parts in approximately normal relations, iced cloths were applied for twelve hours and the intranasal support allowed to remain in place for ten days.

There was absolutely no pain or inconvenience caused by the injection, and the course of the case was uneventful. There is considerable improvement in the appearance of the nose, but it is not as perfect as it is when the ala is held in proper position by the intranasal support (Fig. 4). The result, while not perfect, was such as to make considerable of an improvement in the countenance and expression of the patient. In a case less complicated, with more substance to act as a foundation, as in congenital deformities, it is probable that a still more satisfactory outcome could be obtained. Unfortunately

the writer has never seen a similar case treated by any other method, and so is unable to draw any comparative conclusions. Parker reports one case treated in this manner, but with no improvement after repeated injections.

CASE 2.—Tim M., miner, Irish, aged 28, in a rough and tumble fight was unfortunate enough to have the tip of his nose bitten off by his opponent. He presented himself, ten hours after the accident, at the St. Vincent's Hospital, with the separated portion of his nose wrapped up in a piece of newspaper, and requested that it be sewed in place. Wet dressings were applied to the abbreviated feature and in due time flaps from the cheek were brought over and the defect covered up. The result was satisfactory in covering the defect with skin, but the configuration of the nose was far from satisfactory, owing to the absence of the tip. The front view was not

Figure 8.

so unusual or remarkable, but the profile presented a marked and conspicuous deformity in the absence of the tip; in fact, the distal third of the appendage was missing (Fig. 5).

This was, in a way, remedied, or rather rendered less noticeable by the introduction of paraffin into the region formerly occupied by the extremity of the nose. After the usual cleansing and the regular preparations, about ten minims of paraffin were injected under the flap and in about the median line, so that it would rest on the remains of the cartilaginous septum.

After a month this procedure was repeated, without any undesirable result after either injection (Fig. 6). The improvement was encouraging and the skin over the injected mass normal in every particular and not at all tense or stretched. Other injections were planned, but the patient disappeared.

The introduction of small amounts, at intervals, is undoubtedly to be preferred to the single injection of larger amounts, in any location and under all circumstances, but it is especially true and important when injecting into a region so notoriously non-vascular and prone to necrosis as the tip of the nose. And of still greater importance is this precaution when the overlying skin of this part has been transplanted from a neighboring region.

CASE 3.—Dick G., laborer, American, aged 37, about eleven years ago fell down a stairway and injured his nose. No physician was called to see him, and he paid little or no attention to the injury; he merely remembers that for about a week or so his nose was tender and his entire face swollen. After the swelling subsided he noted a depression in the bridge of his nose (Fig. 7.), which has remained about the same ever since. It caused him no pain or inconvenience other than the slight deformity. The skin over the depression is normal and moves freely over the cartilage and bone.

A typical operation for "sadle-back" nose was performed, technic as described above; fifteen minims were injected at one sitting. The result was a marked improvement in his appearance and was very satisfactory. No redness of the skin over the injected area or any other objectionable features resulted (Fig. 8).

CASE 4.—Mr. W. E., miner, American, aged 32, three years ago, while in a fist fight, was struck on the nose. He had considerable nose bleed, pain and marked swelling the next morning, at which time he consulted a physician, who told him that his nose was broken, and then proceeded to "set" it. After the swelling had subsided a depression of the bridge was noted, which has remained practically the same ever since (Fig. 9). The greatest depression is at about the junction of the nasal bones with the cartilages and in depth is about one-sixteenth of an inch. The skin and overlying structures

Figure 9.

Figure 10.

are normal and freely movable. Treatment consisted of a subcutaneous injection of paraffin, the same as in the case above, about twenty-five minims were injected at one sitting, and the result was eminently satisfactory in every respect (Fig. 10).

CONCLUSIONS.

1. Corning was the first to use solidifying oils in surgery.

2. Gersuny was the first to recommend and to use paraffin subcutaneously as a prosthetic measure.

3. The use of paraffin as a prosthetic substance is still in an experimental stage.

4. The field of usefulness of paraffin subcutaneously in other than nasal deformities is rapidly increasing.

5. Prosthetic operations, undertaken solely for cosmetic effect, should be absolutely harmless.

6. All cases, regardless of the termination, should be reported, as it is only by a study of a large number of cases that the legitimate place of this method in surgery can be ascertained.

7. The special syringe, with screw pressure, is almost indispensable.

8. A general anesthetic is rarely, if ever, indicated.

9. The needle may be made to enter at either the base or the tip of the nose.

10. Rather inject too little than too large an amount of paraffin.

11. In a series of six cases, but one of the numerous objections was encountered, and that a redness of the skin remaining permanently after the injection.

DISCUSSION.

DR. ANDREW W. MORTON, San Francisco—My experience with paraffin injections has been limited to 25 cases. My method is somewhat different from Dr. Connell's. I bring the melting point of the paraffin to 109 degrees by the use of sperm oil, after which it is sterilized by boiling. I am careful to introduce it just as it is beginning to coagulate. It has been proven thoroughly by Dr. Comstock that we must have the paraffin about the temperature of the blood to prevent embolism; it is also well to have the paraffin a little above the temperature of the blood or it will not support the deformity. For the introduction of the paraffin I have been using the Lures glass syringe. I always introduce the needle at some distance from the deformity beneath the skin, allowing the point of the needle to come just beneath the deformity, then I attach the filled syringe and introduce the paraffin.

It has been used in a great variety of cases, but the principal use, in my opinion, is for the saddle-back deformities of the nose. We know there is no class of deformities where we have need of repair more than in those cases. On account of the weakness of the structures, if we use an artificial bridge it is always causing irritation and operations are not satisfactory. In regard to the quantity of the paraffin, I always use a small quantity and repeat it if necessary, but I think this is very immaterial if we do not produce tension, and I think Gersuny has called attention to that; his experience has shown that the amount injected at one time does not make any material difference. I have introduced 40 c.c. at one time; it was in the case of an absent testicle; the man wished to enter the marine-hospital service, but had been rejected. I injected the 40 c.c. at one time, and there was absolutely no change so far as inflammation was concerned, and the day he went away I could not discern which was the artificial testicle except by palpation.

There is one subject that has not been touched on, and that is, what becomes of the paraffin? It was claimed that it could not be absorbed, and would remain in the tissues as paraffin. Recently I had a case which enabled me to make some very interesting experiments. Some of the paraffin had worked down into the tissues and interfered with the breathing space. I took out sections at the end of one, two, three and four months respectively. In the first section you will see paraffin globules; later you will notice that they have been infiltrated with leucocytes and tissue cells. In the last specimen you see an entire absence of the paraffin. This shows that the paraffin is destroyed and its place is taken by connective tissue. In regard to the shrinking of the paraffin, I believe that it will shrink to a slight degree, owing to the small amount of oil which passes off after the injection. As to the principal dangers of the operation, they are: 1, infection; 2, tissue necrosis, or necrosis of the bone; 3, embolism. The infection can be prevented by being aseptic. It is also possible to prevent sloughing, provided you do not use your paraffin at an extreme degree of heat, or produce a great amount of tension on the skin. In regard to embolism, one case of lung embolism has been reported that we attributed to this method. A large amount of paraffin was used, the operation being done in the physician's office for some prolapsed condition of the rectum, and the patient was allowed to enter a carriage and ride home —not a very cautious thing to do. One of the principal points is not mentioned in the report, the melting point of the paraffin. I do not believe that there is very much danger of embolism if we use the paraffin at a melting point above the body heat.

DR. JOHN P. LORD, Omaha—Dr. Connell speaks of the disadvantages of the reddened area. I want to say that our experience with the *x*-ray in the blanching of unsightly red scars has been so satisfactory that I have perfect confidence in it, and the technic should be that the exposure should be of short duration and the treatment should cover a long period of time, care being exercised not to produce a burn. The *x*-ray obliterates the small blood vessels by producing an hyperplasia of the connective tissue cells which squeeze out the blood vessels. Of course, if the blood vessels are of any size I would recommend the use of the electrolytic needle, but if it is simply a redness I think the *x*-ray can be depended on to accomplish very satisfactory results.

DR. WILLIAM J. MAYO, Rochester, Minn.—The methods employed for the repair of depressed noses may be divided into three groups: first, those by a flap from the forehead or cheek or the tip of the little finger, and things of that kind carried to the nasal defect, the best result being that after we got through most people would say that it did not look much worse than it did before. In the second class we introduce a celluloid bridge. Some exceedingly good results have been obtained, but after a time atrophy necrosis takes place in the majority of cases, and we have to remove the celluloid. Therefore, when this paraffin method came out it was taken up enthusiastically, particularly by my brother, Dr. C. H. Mayo, who has had considerable experience in this line of work. He has operated on a large number of cases and the results have been strikingly good. You see the patient come into the hospital with a deformed nose, and in twenty minutes he goes out again, his appearance so changed that his best friends would scarcely recognize him. In regard to those cases in which the deformity is due to a compound injury, if you were to attempt to inject enough of the paraffin to get a good result you would be very liable to get into trouble, on account of the adhesions of the skin to the deeper parts. In those cases a small knife is introduced and the tissue cut loose a few days previous to the injection; the paraffin can then be injected without trouble. It is advisable in some cases, where you have to sever the tissue in this manner, to use an injection of saline solution to loosen the tissues still further, and follow this in a few days by the injection of paraffin.

MULTIPLE PERIOSTEAL SARCOMATA OF THE CRANIUM,

WITH INVOLVEMENT OF RETROPERITONEAL LYMPH NODES, AND ATTENDING SEVERE, PROBABLY PERNICIOUS, ANEMIA.*

WALTER L. BIERRING, M.D.

Professor of Theory and Practice of Medicine and Clinical Medicine, University of Iowa.

IOWA CITY, IOWA.

Through the exhaustive work of Warthin the retroperitoneal lymph nodes or hemolymph glands have been given an important rôle in human pathology. Changes in these hitherto frequently unrecognized structures are specially significant of anemia and processes accompanied by hemolysis.

I feel that the case, a description of which I wish to submit, illustrates this relationship in a special way, and offers a few additional points of pathologic interest as to warrant its being presented before this section.

The case occurred in the practice of Dr. C. B. Kimball of West Liberty, Iowa, to whom I feel indebted for calling my attention to it and furnishing me with the principal clinical data, which in brief were as follows:

A. B., girl 5 years of age, who until three months before her death enjoyed good health and had been regarded as an unusually robust child. When first seen by her medical attendant she presented a mild degree of anemia, a slight rise of body temperature, some malaise, impairment of appetite, and physical weakness. During the period of illness mentioned, the anemia assumed a progressive pernicious character, the pyrexia

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. L. Hektoen, F. B. Wynn and W. S. Hall.

of one to two degrees continued, and the emaciation and physical weakness proportionately increased.

At my first opportunity to see the case, Oct. 5, 1902, the anemia was quite pronounced and the child appeared weak and listless. There was no enlargement of any of the palpable lymph nodes, but over the frontal region a soft subcutaneous sessile tumor-like enlargement, about three centimeters in diameter, was observed, which was apparently attached to the frontal bone.

A hemic murmur was noted over the base of the heart; the lungs were negative; the splenic area of dulness not increased, and the organ not palpable. Area of hepatic dullness not increased, Urine acid, specific gravity 1,022; chemical tests negative. Signs of intracranial pressure were not present.

I saw her again one week before her death, when she appeared in a semicomatose state, the anemia being very profound and emaciation specially marked. There was no noticeable change in the different lymph nodes. The spleen was not enlarged, though a perceptible yet slight enlargement was noted in the hepatic area of dullness. Urine negative. Lungs negative. Hemic murmur still very pronounced over the basal region of the heart.

The frontal tumor had apparently enlarged and four more tumors were now to be detected over the parietal and occipital bones, and one over the left mastoid region. A slight degree of exophthalmus was present. The blood count revealed erythrocytes, 982,000; leucocytes; 9,600; hemoglobin, 30 per cent. Differential count in 17,874 red cells revealed: megalocytes, 473; microcytes, 328; poikilocytes, 45; megaloblasts, 23; normoblasts, 19; leucocytes, polymorphonuclear, neutrophile, 68.6 per cent.; eosinophile, 2.26 per cent.; large lymphocytes, 2.52 per cent.; small lymphocytes, 26.46 per cent.; myelocytes (neutrophile), 63 per cent. Proportion of white to red cells, 1 to 113. Most of the erythrocytes were about the average in size

At this time a clinical diagnosis was proposed of multiple periosteal sarcoma, with attending severe secondary, probably pernicious, anemia.

Report of Autopsy.—Nov. 20, 1902. General emaciation very marked, the skin being extremely pale. No change noticeable in the cervical, axillary, clavicular, and inguinal lymph nodes.

Skull and Cranial Contents.—After removing the scalp seven distinct circumscribed tumors are observed attached to the skull, appearing as cushion-like growths and distributed as follows: One over the frontal bone, two on the left parietal, one on the right parietal, one over the right mastoid, and two on the occipital bone. The tumors are of soft consistency and vary in color from deep gray to pinkish and reddish gray; in diameter they range from 3.5 to 6 centimeters. The growths extend above the bone about one centimeter, and are well defined from the skin and subcutaneous tissues. After the skull cap is removed the tumors are seen to have completely penetrated both the outer and inner tables, the latter presenting a distinct honeycomb appearance; the growths also involving the dura mater.

A considerable amount of subdural serous effusion is present. The brain is pale and anemic, but otherwise negative.

Diaphragm at Fourth Rib, Right and Left.—Pleura and pericardium negative; heart valves intact, musculature anemic and somewhat atrophic. The lungs are pale and freely movable with some passive congestion in the lower lobes; bronchi pale, containing a grayish foamy liquid. Esophagus contains a small amount of foamy mucus, mucosa pale.

No fluid in the peritoneal cavity. The spleen is not enlarged, on section it is a pale brownish red; pulp is soft and bleeds readily. The liver appears slightly enlarged; the surface is smooth; on section the surface is cloudy, and of a pale red chocolate color; a slight fatty smear is left on the knife; outlines of lobules distinct; throughout the liver substance a limited number of light-colored circumscribed areas are noted, ranging from 0.3 to 0.8 centimeters in diameter and having the macroscopic appearance of the cut surface of the cranial tumors. Gall bladder negative. Kidneys are pale; a retention of fetal lobulation exists, otherwise negative. Bladder negative. Pancreas and suprarenals negative. The stomach and intestinal mucosa is pale, but negative in other respects. Mesenteric glands are negative.

In the retroperitoneal region a marked enlargement is noted in the prevertebral lymph nodes or hemolymph glands; extending from the brim of the pelvis upward along the aorta and vena cava are sixteen enlarged and dark red glands, forming in reality a dense mass involving an area of 5x12½ centimeters; the larger glands being 2x3½ cm. in dimensions, and of a dark red color; the smallest examples having a coffee-bean shape, 0.6x1 cm. in diameters; pale and red nodes are noticed placed side by side. A few of the smaller glands extend along the renal vessels. The entire mass is imbedded in fat and very closely connected with the surrounding blood vessels.

The long bones were not opened owing to the restrictions placed on the autopsy, but the cross section of the sternum presented the hemorrhagic appearance of marrow peculiar to severe anemias. The extreme emaciation of the body permitted a good examination of the surface of the different bones, and disclosed an absence of any periosteal growths or enlargement of the bones.

Histologic Examination.—The tissues were all studied in serial paraffin section, and stained by hematoxylin and eosin, Van Gieson's, and Mallory's stain for connective tissue, and the potassium ferrocyanid method for demonstrating hemosiderin.

Periosteal Tumors.—While the general histologic picture is that of round cell sarcoma, there is some degree of variation between the several tumors. The cell element consists of a round cytoplasmic mass with a nucleus rich in chromatin, the latter varying in size, frequently granular, and seen in varying stages of mitosis; a delicate intercellular reticulum is present; the fibrous tissue stroma following principally the blood channels forms an alveolar arrangement in some portions and presents the type of an alveolar sarcoma; again the prominence of blood vessels and hemorrhage give a picture resembling angiosarcoma, while the light gray colored tumors in section reveal a type like lymphosarcoma.

The ordinary lymph nodes present no definite histologic changes. Heart and lungs are negative. Brain is negative.

Spleen reveals a slight degree of fibroid hyperplasia; hemasiderosis is very marked. Adrenals, kidneys and pancreas are negative. The stomach and intestines reveal some signs of catarrhal inflammations.

Liver.—Cloudy swelling in the cells, lobules are not well defined, and interlobular interstitial connective tissue is not increased. Distributed throughout the liver substance are well-circumscribed areas representative of metastatic growths secondary to the periosteal tumors, evident by reason of their identity in structure. Their histology consists of small round cells arranged in distinct alveoli formed by rather delicate fibers of connective tissue, resembling the picture of alveolar sarcoma. Hemasiderosis is present.

Hemolymph Nodes.—The smaller nodes 0.5 cm. in diameter present a histologic picture resembling the so-called marrow-lymph variety of hemolymph nodes, consisting of well-defined sinuses apparently lined by endothelium; throughout these sinuses a delicate reticulum is noted holding in its meshes principally red blood cells and a few leucocytes. Among the red cells normoblasts are observed and an occasional megaloblast. A few eosinophiles are seen. Some of the blood sinuses are very short and irregular. The constituent lymphoid tissue adjacent to the blood sinuses is made up of columns or bands of cells chiefly lymphoid (small mononuclear) in character; these cells also lie in a very delicate reticulum; large mononuclear lymphocytes are observed in small numbers, frequently mitotic figures are seen and again some of the nuclei appear also completely disintegrated. Large collections of hematic pigment are seen in the lymphoid area and the iron reaction is brought out by application of the potassium ferrocyanid stain. A few hyaline bodies are noted.

In the larger examples of hemolymph nodes, especially those having dimensions 2x3½ centimeters, the round or lymphoid cell infiltration completely obscures the essential hemolymph structure.

The cells are arranged in columnar-like collections divided by bands of fibrous connective tissue of greater or less density, forming alveolar areas resembling the picture of alveolar sarcoma; again in some areas the resemblance to lymphosarcoma is very striking. The cells contain large round granular nuclei, with varying figures of mitosis, resembling the cells of round-cell sarcoma.

In the peripheral portions of the enlarged nodes well-defined areas of red blood cells are seen and the lumina of well-formed blood channels are observed, some of which resemble closely the sinuses of hemolymph nodes except that the delicate intercellular reticulum is not apparent. Small areas of caseation are present in some of the cell areas. In all of the enlarged hemolymph nodes hematic pigment is abundant, some of which responds to the iron reaction, phagocytes containing hematic pigment being noted in the blood channels.

Unfortunately the circumstances of the autopsy prevented the histologic examination of the bone marrow.

Summary.—The features that invite interest in connection with this case are the multiple periosteal sarcomata confined to the cranial periosteum, the secondary involvement of hemolymph nodes, and the attending severe, probably pernicious, anemia. The origin of the tumors from the periosteum seems evident by reason of the intimate connection with the surface of the bones; the involvement of the inner table and extradural tissue being the result of extension.

If one of the periosteal tumors is to be regarded as the primary growth and the others as secondary nodules, it would seem like rather an unusual form of metastasis, and I prefer to regard them all as primary tumors.

It must be evident to all that considerable confusion exists in the literature on the various sarcoma-like tumors involving the osseous system, especially those which are attended by leukemic or pseudoleukemic change in other tissues. This is principally true of the multiple periosteal tumors having the histologic character of round cell sarcoma and described as chloroma and lymphosarcoma in which the relationships to pseudoleukemia is rather intimate.

Chloroma is frequently characterized by multiple periosteal plate-like growths especially of the cranium with metastasis in the lymph nodes, different portions of the skeleton and internal organs. In structure they resemble lymphoma or lymphosarcoma and contain a greenish pigment.

The absence of pigment in the case in question, especially in the fresh specimens, excludes chloroma, but in some other respects there is a great resemblance to this peculiar tumor process.

Closely related to chloroma are those non-pigmented pseudoleukemic periosteal tumors having the structure of lymphosarcoma which have been extensively considered by Claus under Marchand's direction, the same appearing as cushion-like growths on the skull, sternum, ribs, pelvis, spinal column and femur with tumor formations in the tonsils, lymph, nodes, liver, and marked enlargement of the spleen. Lazarus, Gussenbauer, Chiari, and Dittrich have described more complicated cases in which the spread of tumors in internal organs was more prominent, giving the impression of a general metastasis, the relation to the primary periosteal localization of the malignant lymphoma, though, being well defined.

As to the tumor nodules in the liver and involvement of the hemolymph nodes with their identity in histologic structure to the primary cranial growths, the findings warrant regarding them as secondary or metastatic formations.

The close resemblance of the arrangement of cells, with numerous mitotic figures in the enlarged hemolymph nodes to that in the periosteal growths is so striking as to permit of no other conclusion than that they are metastatic.

Both of the secondary manifestations must be regarded as examples of vascular metastases, and it must be due to the connection of the hemolymph nodes with the circulatory system that they are more liable to involvement than the other lymphoid structures throughout the body. The fact that the lungs were not involved by metastasis may be attributed to the relatively small size of the constituent tumor cells permitting them to pass through the pulmonary circulation.

That the attending severe, probably pernicious, anemia is the result of hemolysis, is evident from the general blood changes and the hemosiderosis in the spleen, liver and hemolymph nodes. The blood findings are very similar to those of pernicious anemia.

This case offers a further illustration of the relationship between changes in hemolymph nodes and the severe anemias. According to Warthin there is a certain amount of normal hemolysis taking place in these glands, and the hemolysis of severe or pernicious anemia differs from the normal only in degree. As the last named condition is probably due to some circulating poison, the nature of which is as yet unknown, so in the case described it is a circulating sarcoma process, which by reason of its involvement of the hemolymph nodes led to an increased hemolysis in these structures.

It is in this class of sarcoma-like tumors, including chloroma, and those of lymphosarcoma and pseudoleukemic type that a parasitic cause will probably ultimately be discovered.

DISCUSSION.

Dr. E. R. LeCount, Chicago—There is an intimate connection between the tumors in the case described by Dr. Bierring with the growths observed on the one hand, as multiple myelomas, and on the other in cases of chloroma. Had the tumors described in this case been possessed of a greenish cast Dr. Bierring would no doubt have considered his case as one of chloroma. The absence of the peculiar color does not seem to me sufficient reason for excluding the growths in this case from those in pseudo-leukemia, chloroma, multiple myeloma and acute leukemia. Therefore, I would object to the term sarcoma and prefer some name which would indicate their position correctly as examples of multiple growths unconnected with sarcoma in method of origin, growth and extension; for example, "multiple periosteal lymphomata" or "a case of chloroma with absence of the usual pigmentation." The term sarcoma has little to do with tumors that are primarily multiple.

Dr. Henry A. Christian, Boston—Dr. Bierring speaks of the difficulty in such tumors of determining which is the primary growth. The relation that exists between the more or less diffuse processes in bones and definite tumor masses is a very close one, and to say that a certain growth is primary and the others are metastases is very difficult in a case like this. A great many similar examples have been reported and I would like to add one. It was a case in which both kidneys were very much enlarged, four or five times their normal size, but they were not distorted and there were no definite tumor masses in the kidneys. They were both of the same size. Microscopic study showed the kidney tubules to be separated by a growth which proved to be of the nature of a round cell sarcoma, a diffuse sarcoma appearing simultaneously in both kidneys. The bone marrow of the femur showed similar changes. The question is, whether we have here a tumor of the bone marrow metastasing in the kidneys, the development in the kidneys of a tumor, bilateral and simultaneous in origin, or have we some general diffuse condition of the bone marrow which has not found its expression in cellular changes in the blood vessels as in leukemia, but has affected certain organs in a similar manner as the bone marrow.

Dr. Walter L. Bierring, Iowa City, Iowa—I appreciate what Dr. LeCount has said in regard to the terminology of this condition, but I labored for a long time in trying to name this process, and while I know that the term sarcoma is not entirely satisfactory, it seems to me that the various round-cell growths variously termed as chloroma, lymphosarcoma and small round-cell sarcoma are all more or less connected, and I think some day they will be cleared up and shown to be of parasitic origin.

I made a number of inoculations from fresh tissue material under proper precautions on the various culture media, but was unable to obtain any results. All tests for albumin and albumose in the urine were negative.

I regret that the restrictions of the autopsy prevented an examination of the long bones, but in this case I am still inclined to think that they were not particularly affected.

POLITICAL AND PROFESSIONAL ETHICS.*

JAMES D. LOVE, A.B., M.D.
JACKSONVILLE, FLA.

I believe that the majority of physicians concede the truth and justice of the philosophy of Bacon, who writes, "I hold every man a debtor to his profession; from the which as men of course do seek to receive countenance and profit, so ought they of duty to endeavor themselves by way of amends to be a help and ornament thereunto." The very acknowledgment of such indebtedness carries with it obligations and duties which we as a body and as individuals can no more shirk than we can the duties and responsibilities we owe our patients. Hippocrates recognized the indebtedness he owed his profession, despite the crudity of medicine as it was then taught and practiced, and notwithstanding the less respected position then occupied by the medical fraternity. Probably the first universally received code of ethics, as offered by this worshiper at the shrine of justice and science, was inspired by the realization of this very indebtedness.

Notwithstanding the lack of erudition and despite the prevailing practice of charlatanry that existed in ancient and medieval times, medical men have, as a body, recognized certain obligations as being due their fellow practitioner and the community, and have commanded and received a certain respect as the inalienable endowment of their profession. We note, too, that as medical knowledge and scientific attainment have become more universal and of more value that the morale of our profession has improved, and with more honest methods prevailing there exists a more perfect sense of our obligations and duties.

Our profession has for ages been composed of men whose high sense of honor and integrity and whose moral and intellectual qualifications entitled them to a social standing second to no other class. The true physician has been and is clothed with habiliments of dignity which it becomes our duty to preserve and to hand to posterity in an unsullied state. The young man beginning his career as a physician receives as a heritage from his profession certain immunities, certain social rights and privileges and certain claims to the respect and esteem of his fellow beings, which by his own unassisted efforts he could only hope to win after years of unremitting devotion to the loftiest moral and ethical principles. It is this unsolicited and unearned inheritance which places the physician in the very springtime of his career under obligation to his profession. While in isolated cases this sense of indebtedness is ignored and the title of physician is prostituted by charlatans, yet I am proud to believe that as a body we have never been justly charged with unfaithfulness to our obligations.

The physician who wilfully devotes his entire efforts to his patients or to his family, who isolates himself from his fellow practitioners, who neglects his political and social duties, who contributes no assistance to medical societies and whose life is spent in his patient's behalf and his own self-aggrandizement, no matter how conscientious are his efforts and how honest his intentions, is not only remiss in the discharge of his entire professional obligation, but his narrow existence has unfitted him for the discharge of some of the most sacred duties he owes his fellow man. When he fails to exert his influence for the elevation of his profession and for increasing its sphere of usefulness, he can not excuse his course with the plea that the demands made on him by his patients are paramount in importance to the duty he owes his profession. For he who persistently adheres to this narrow course, who never looks beyond the horizon of his own private needs, defeats ultimately his own ends by lessening his influence in his immediate sphere.

The average physician is not and obviously could not be a politician after the usual acceptance of the term, but there is none among us who does not recognize the existence of certain political evils which by legislation might be corrected, and certain political reforms that would result beneficially to all. It is an established though unfortunate fact that there is in the public mind a deep-rooted prejudice against any interference on the part of the medical profession in political affairs. Let us as a body pass any resolutions or endorse any enactment for the preservation or improvement of the public health, or for the elevation of the standard of our profession, and our cause is at once prejudiced in the minds of the average individual, who is ready at once to attribute our acts to motives of selfishness and self-aggrandizement. It is only when through the medium of threatened or existing epidemics the public is brought to realize its dependence on the medical practitioner that we as a profession are in a position to dictate legislation suitable to our own and the people's needs. It is a matter of common observation that in the absence of epidemic sickness every community is singularly indifferent to the poor sanitary and hygienic conditions that may prevail, and are peculiarly resentful of any imputation on the healthfulness of their people. Unmindful or ignorant of those factors that might better their condition they lull themselves into a state of fancied security, ignore the advice of the physicians and are only awakened from their lethargy by the frightful ravages of some destroying epidemic. Then it is that they turn to our profession for deliverance, and then it is that the ear of the politician becomes receptive to our council.

I speak advisedly when I say that in our entire country there is not in a single statute book a law passed at the instigation of the medical profession that is not productive of more benefit to the masses of the people than to the physician. I challenge anyone to produce a single statute bearing on medical matters that can properly be construed as class legislation. In the history of legislation in Florida I challenge the production of even a single defeated bill which was endorsed by our profession and which had not for its prime intent the protection of the people of our state. And yet, despite this, any combined effort on our part to influence legislation is at once regarded with suspicion and fails of

* Read before the Florida Medical Association, at St. Augustine.

accomplishment on account of the designing, sordid and selfish motives that are attributed to us.

Our profession unanimously endorses a compulsory vaccination law because in the hands of medical men are statistics proving the miraculous preventive powers of vaccination against smallpox, and it is our contention that it is one of the fundamental laws of sociology that no man has the right to jeopardize the health and life of a community when by the observance of proper precautionary measures it may be avoided. Immediately there is raised the hue and cry that the autocratic doctor is aiming at the personal rights and privileges of the people, and as unselfish a bill as was ever presented to a fair-minded people goes down in defeat. Year after year are bills looking to the elevation of the standard of our profession and the protection of our people from charlatanry and imposition introduced in our legislature and to the din of vituperation and the slogan of interference with personal liberty our colors trail in the dust.

The enlightened physician is broad enough to realize and acknowledge that he as a component part of a community best subserves his own interests by best serving his people. He acknowledges that from a purely commercial point of view the result of epidemic disease would, by impoverishing his community, prove nearly as disastrous to him as to his people, but moved by a humane and altruistic spirit the doctor finds his chief reward in protecting and preserving the life and health of his fellow men even if, as often happens, his efforts encounter the opposition of the very ones he seeks to befriend. If our profession was composed of men of less charity and forbearance, an inappreciative public would be left to their own impotent endeavor to solve the problems of sanitation and protective medicine. It is no wonder that there is a tendency on the part of some of us to abandon a thankless undertaking, for it sometimes seems that in spite of our most loyal efforts it will always be thus, "truth forever on the scaffold, wrong forever on the throne."

Why the populace are less responsive to concerted action on our part than to individual effort can, in my mind, be only explained on the ground that when physicians band together for any accomplishment they are regarded as a trust, and the public generally is antagonistic to organization.

Compare this prejudice to medical organizations with the general approval with which our commercial bodies are regarded, and the result of such comparison is almost disheartening. If a board of trade endorses certain legislative enactments for the protection of the financial interests of a community, the masses of the people have sufficient confidence in the integrity of this board to wisely rely on and be governed by their endorsement. The press will come to their assistance and, if need be, a fund is created for the promotion of the enterprise.

Let a medical organization, on the other hand, originate or endorse measures which have a vital bearing on the health of the same community, and to whom will it look for support? The press in certain instances is subsidized by advertising charlatans, and the people, instead of according us their moral support, are either indifferent to our efforts in their behalf or are ready to rise in denunciation of our most honest purposes. The same confidence that is accorded us as individuals is denied us as an organization. Probably this is because the people, not being aware of their needs, resent as an interference any unsolicited or unrewarded action in this direction; for as concerns other matters of even less importance where the physician's assistance and council is solicited and remunerated, he must needs feel complimented and gratified over the confidence that is reposed in his integrity, ability and veracity. Courts of justice are guided or influenced by our expert testimony, even when the very life and liberty of people are at stake. Civil and military authorities rely implicitly on our statements and opinions, and there is a liberal and generous spirit manifested toward our individual efforts which renders it remarkable that our concerted political influence is so limited. I believe that little has ever been accomplished by the mere adoption of resolutions by medical organizations; and, on the contrary, I believe that the influence we as individuals might exert politically is practically unlimited. And when we note that through defective or unjust legislation our professional institutions are endangered, it becomes as much our duty to exert our political influence as to protect from violation the sanctity of our homes.

I believe that we neglect to utilize our peculiar advantages to educate the people to a realization of our needs and the impositions that they are subjected to at the hands of impostors and degenerates. The physician is in close contact with his patient at a time when his ear is most receptive to instruction and his nature most responsive to our honest appeal for justice. We watch the busy practitioner in the discharge of his daily duties. He it is who ministers to the sick and suffering around us, his the face to welcome to returning life and health those stricken by disease, his the voice to lend comfort and courage to woman on the verge of maternity, his the hand to close the eyes for their eternal sleep and to wipe the death damp from the brow. His the first voice to tender solace and comfort to that family visited by the grim destroyer and bid the stricken souls take hope again. To his patients he is more than a friend and his opportunity for exerting an influence is without limit and without rival. I ask, are we not remiss in the duty we owe our profession when we fail to enlighten the public as to our most pressing needs?

The physician, in order to practice his profession in our state, must, in compliance with the statute, have graduated from a reputable medical college and must further appear before a district board of medical examiners, whose duty it is to pass on his qualifications to practice medicine. An osteopathist, a spiritual or mental healer or Eddyite can, with practically no preliminary preparation and with an absolute immunity from any examination as to his fitness, treat any disease or injury in the domain of medicine or surgery. I protest against the discrimination of requiring the medical man to prove his fitness and placing no restriction on those who are obviously unfit from lack of scientific attainment to practice medicine in any of its branches.

Not less far reaching in its baleful effects is the sale and advertising of patent nostrums throughout our state. I admit the handicap that our profession labors under when it denounces a patent nostrum or appliance of any kind, and from personal experience I am aware of the motives that are attributed to us. But it is no less our duty to make some personal sacrifice and try to create a healthy public sentiment that will protest against this growing evil. In battling with this evil we shall find as our opponents some of our most prominent national legislators, some of the executives of our principal states, the clergy and men and women of every sphere and station in life. That these people, with their pure and irreproachable intentions, will endorse patent nostrums

and quackery that are in most cases not only useless, but positively dangerous, can only be explained on the ground of their ignorance of the evil consequences. Thus we see that it is not only the masses, but the educated and well informed who need to be protected from the results of their own folly.

I protest against the assistance that is accorded quackery by the entire press of our country. I believe that with a very few exceptions newspapers throughout this land will lend their advertising columns to the teaching of doctrines known to be false and for the promotion of the sale of drugs and appliances that are only intended to be used for criminal purposes. Men who are recognized and admitted to be quacks and impostors can, for the slightest compensation, secure the co-operation of and completely subsidize our press for the purpose of defrauding the public, and thus endanger the health and life of a community. That through the medium of the press charlatanry thrives is best evidenced by the fact that as a business proposition the efficacy of newspaper advertisement is recognized by quacks and their patronage continues unabated. Abortifacients of all kinds are daily brought to the attention of the public through the medium of the press; and when a paper knowingly advertises any drug or measure which on the face of it has for its purpose the accomplishment of a crime, judged from every law of morals, the proprietor of that paper is guilty of complicity in crime. That they salve their consciences and excuse their complicity by disowning responsibility for the results of what they term legitimate business, is but a puerile plea and is an admission on their part that for a monetary consideration the columns of their paper are open for any fraudulent accomplishment that is without the pale of the law. If the physician in his practice should advocate the employment of the drugs that are with full license advertised in our press it would be regarded as not only a violation of our statute, but of a higher ethical and moral law as well. What the physician can not and would not do is with impunity accomplished through the advertising columns of our papers; and though it is well understood that death is a frequent result of this disgraceful newspaper complicity, their columns continue to reek with this criminally vile, obscene and noxious effluvium. The efforts and teachings of a hundred thousand physicians are set at naught by this very pernicious practice, and yet it continues unabated. The responsibility is saddled on the ignorant people and the demoralizing and often sad spectacle which we as medical men witness as a result of this disgusting abuse, is set aside by the newspaper proprietor as something aside from his province and unpleasant to contemplate.

As sacred a duty as that we owe the public is that duty we owe our fellow practitioners, and he who isolates himself from his professional workers and is left to his own devices and endeavors, robs himself of the sweetest and most comforting reward of his efforts. To our medical societies is due a full measure of thanks for the spirit of good will and harmony that pervades our ranks to-day. Through their medium we are brought to realize the importance of unifying our interests, to think and act in common, and are taught to feel our mutual dependence on each other. In the hands of no others is a physician's reputation so safe as in the hands of his fellow workers. A physician's whole life is but the history of his accomplishments and endeavors, and no one can so sympathize with his efforts as his confrères.

We watch the physician as he begins his career; the shadows are long in the west, life, strength and commendable ambition are his and roseate dreams fill his fancy. Though alternately elated and disheartened by his successes and failures, he finds with each passing year a more complete reward for his honest efforts. But no matter what might be the measure of his success there is no reward to him so wholesome and pure as the hearty handshake, the friendly nod and blessed words of approval of an older physician. We follow him still further in life's great battle. Throughout every turmoil and strife the physician is found and his presence is inseparably linked with men's greatest sorrows and most perfect joys. Success as a physician may have crowned his efforts, popular adoration may be his, and the world unites in according him just praise for his accomplishments, yet no popular applause, however loud, can overrule the judgment of his fellow workers. Without their friendly council, good will and approval his success will count as naught and his life and reputation will be only a glittering fraud. We follow him still further as he stands in the dim shadows; his race is almost run; the best days of his life, his strength and vitality have been freely given for the betterment of his fellow man, and now the "frosty fingers of time have touched him and turned his locks into a snowy crown." Yet better than the contemplation of his past success the brightest star in all his firmament is the seal of approval set on his life by the members of his own profession.

Until medical men can live together in harmony and concord, until they learn to recognize and admit the good, and cover with the cloak of charity the faults of their fellow workers, then only can they prove their worthiness of the perfect trust and confidence of the laity in their altruism and disinterested motives. I acknowledge with deep humility that we are too prone to turn a willing ear to the tongue of slander and too prone to doubt the honor and purity of those who are most entitled to our perfect confidence. Yet I believe that our profession is on a more exalted plane to-day than ever before, and dissension has no rightful place in our ranks. Every discordant note that emanates from our medical societies and every estrangement between members of our profession serve but to justly disparage us in the public mind and lessen the respect and confidence that is accorded us.

There are most respectable citizens in our profession who are not members of our medical societies and whose standing among medical men is not what it should be, yet these men have in them all those elements which go to making reputable physicians. We owe it to our profession to use our utmost endeavor to induce these men to abandon their selfish and isolated course and to identify themselves with our association. There would be a mutual profit that would ensue to all in consequence of this, and a fraternal communion with men of exalted ethical principles would make of these men useful and honorable members of our body. With an increased knowledge of their fellow workers and increased appreciation of the commendable purposes of our association they would become better men and better physicians and, "like the stained web that whitens in the sun, grow pure by being purely shone upon."

In improving the tone of our profession we advance our material interests by proving to the public our worthiness of their trust and confidence. Merit and genuine worth will not long remain unrecognized and our only hope for a full recognition of our political requirements is based on a strict observance of professional ethics.

CHOREA AND RHEUMATISM.

Probably no subject in medicine has been more discussed in recent years than that of the possible etiologic relationship between the simple chorea of childhood and acute articular rheumatism. Nevertheless, there is at the present time no subject in which there is more need for clinical observation and for the collection of valuable statistics by the general practitioner than in this problem of the possible connection between these two very familiar affections. At the recent meeting of the British Medical Association two meetings of the Section on Children's Diseases were taken up with the discussion of chorea and rheumatism, and some of the best special authorities in pediatrics took part in it. The report of the section meeting in the *British Medical Journal*[1] shows that while there is an almost universal agreement that chorea and rheumatism are frequently connected, it is now generally admitted that it is more because rheumatism is an infectious disease, with a liability to affect serous membranes, and consequently those of the brain also rather than because some specific action of the presumed microbe of rheumatism acts on the nervous system and sets up the convulsive movements we know as chorea.

Dr. Lees, in opening the discussion on rheumatism and chorea, said that while attacks of chorea are, in his experience, preceded by rheumatism less than once in three times, subsequent attacks of rheumatism occur in chorea patients in considerably more than one-half the cases. An attack of chorea, then, would seem in a sense to be the equivalent of an attack of acute articular rheumatism occurring particularly during the growing period in childhood when the nervous system is under the strain of a constant effort to keep up with its duty of providing innervation for the growing body. In the great majority of cases, Dr. Lees is inclined to consider chorea as a form of cerebral rheumatism. It is thought to affect not only the serous membrane, but also portions of the cortex, hence bringing about the explosions along motor nerve tracks that lead to the characteristic convulsive movements.

Following out this principle of the equivalency of rheumatism and chorea, Dr. Lees has found that the best possible remedies for chorea are the salicylates in what would ordinarily be considered forbiddingly large doses. He gives ten grains of sodium salicylate, with double this amount of sodium bicarbonate every two hours during the day and every three hours at night, so that the child gets altogether ten doses of the two remedies. The original hundred grains of sodium salicylate thus given each day is gradually increased to 150 grains a day, and finally to 200 grains, unless symptoms of salicylism, and especially the deep inspiration simulating the air hunger that occurs so often in diabetes should be noted. Without the combination with the alkali, salicylic poisoning is much more apt to occur, and seems to take the form of the so-called acidemia of diabetic coma.

Not many of the prominent English pediatrists would agree with the suggestion to give salicylates in such large doses as this, and Dr. Ashby, for instance, while confessing that chorea is very frequently associated with rheumatism and consequently should be helped by salicylic remedies, added that undoubtedly many cases of chorea would be seriously injured by large doses of such coal-tar products. He called attention particularly to the fact that chorea not infrequently occurs in overgrown anemic girls, apparently as a consequence of the lack of control over the motor nervous system in conditions in which the blood is lacking in important constituents. In these cases the salicylates are not only not advisable, but are absolutely contraindicated, quite as much as they are in cases of rheumatism after the acute febrile painful stage has passed and the patient is suffering from the intense anemia which develops so rapidly in many cases of acute articular rheumatism.

Dr. Poynton suggested that chorea is practically always due to a microbic cause. The microbe found in many cases is of the streptococcus group and resembles organisms known to occur in rheumatic conditions. Pure cultures of this microörganism when injected into animals have been known to produce choreic movements, and in certain cases also have given rise to joint lesions. These discoveries point to the fact that chorea is due either to focal lesions in the central nervous system of patients or to the fact that the toxins in certain persons whose nervous systems are not in stable condition have a selective action on the motor tract that leads to the nerve explosions represented peripherally by the choreic movements.

As a matter of fact, however, the whole discussion brings out the practical conclusion that the absolute connection between rheumatism and chorea is not yet demonstrated. One unexplained fact of great interest is that while rheumatism is more common in males, chorea is more frequent in females. Neurologists, too, point to the thoroughly accredited observation that a serious fright or some severe emotional strain may be followed by a frank attack of chorea which runs just the same course as the corresponding affection that occurs apparently as the equivalent of an attack of rheumatism. That there is some connection between infection and chorea there is very little doubt, though the infectious material is by no means necessarily limited to the so-

1. Brit. Med. Jour., Aug. 29, 1903. Abstract in THE JOURNAL A. M. A., Sept. 19, p. 750.

called rheumatic group. Other children's diseases may have as a sequel an attack of chorea and even such simple infections as a furuncle, or a whitlow may be followed by a regular attack of chorea. In a word, the subject is still open for significant observations, and as practically every practitioner is in a position to secure valuable data for the solution of the problem, it remains one of the most interesting in the field of clinical medicine.

SUGGESTIVE THERAPEUTICS V. HYPNOTISM.

The recommendations of the Mendel Commission of 1902 as regards the use of hypnotism are combated by Forel at considerable length.[1] He holds that hypnotism has a proper and very important place in therapeutics, and that its legitimate use should be a part of the instruction of the medical student. The lack of this he apparently considers a serious defect in the medical education of the day. The Journal has expressed its opinion at various times in regard to the therapeutic use of hypnotism, and, notwithstanding the high authority of Professor Forel, we can not agree with him as to its importance. We do not, of course, mean here to imply that suggestion is not of importance; suggestion in some way or another, consciously or unconsciously, is daily employed by every physician, and is the sole basis of the success of the Dowieites, Eddyites, etc. It has its limitations, however; there are limits to normal suggestibility, and it is altogether possible that even waking suggestion may have its perils in special cases. Nevertheless, it is a subject that deserves to be more studied by the profession, and when it can be used honestly it will often be found a valuable aid in treatment of a special class of cases.

It is not necessary or even expedient that because it is used successfully by humbugs that we should adopt their methods. No honest physician could pretend to the special magnetic or divine power which is the essential element of the success of charlatans of the pseudo-religious and mind cure variety. The final, as well as the immediate, results must be considered. Hypnotism, as we understand it, is another thing, though Forel considers it the same. The difference is more than one of degree; it is practically the difference between somnambulism and the waking state; hypnotism is a sort of induced trance state or somnambulism, and this is a pathologic rather than a normal condition. Hypnotism, as it is generally understood by the profession, and we believe the understanding is a correct one, is very much more than suggestion; it is the abnormal excitation of hysterical disturbances of consciousness and even what we may call epileptiform conditions of amnesia and, in some cases, double consciousness. Forel is hardly frank, therefore, when he says that sleep is a useful element in treatment, and our adding more or less of it to suggestion is legitimate; hypnotic trance conditions are not abnormal physiologic sleep, nor are they used as such by hypnotic therapeutists to any extent. Nor do we believe that he is correct in calling hypnotism harmless; its dangers have been repeatedly illustrated, and we think they often outweigh its possible advantages, even in skilled hands.

The history of hypnotism itself shows how little it can be relied on. It has been before the profession for the better part of a century, has had many advocates fully as enthusiastic as Professor Forel, and, while he and the other later investigators unquestionably understand it better and utilize it more scientifically than their predecessors, nevertheless they have not gained for it a satisfactory standing with the scientific medical profession, as the report of Professor Mendel's commission shows. The profession is, we believe, more than ever awake to the importance of suggestion, not only on account of the possibilities of its legitimate use, but also on account of its constant employment by quacks and impostors. It leaves hypnotism largely alone, and the number of those who employ it will, we think, be less in the future than in the past. It will doubtless continue to be employed by some special workers who will claim its advantages as they have in the past, and it will probably be useful in a limited number of cases, but we should dread to see its popularization as a therapeutic method. That Forel, Bramwell and others have seen no special bad effects from their careful and skilled use of hypnotism does not prove that it would not be a peril in other hands. Moreover, there is always in our minds the possibility that they do not look on the subject with an altogether impartial eye. That there have been serious effects from hypnotism is undeniable; many cases have been reported, notwithstanding the fact no one would naturally like to report evil results from such measures employed for therapeutic results. We believe that the opinion of the German Commission should carry more weight than the utterances of special advocates and enthusiastic workers in this special line, however eminent they may be.

1. Muenchener Med. Wochen., August 11.

THE DOCTORATE OF PHILOSOPHY IN MEDICAL SCIENCES.

Science recently published a review of the doctorates of philosophy conferred by American universities during the past six years which reveals some facts of interest in connection with medical education. Two hundred and sixty-six doctorates were conferred last year, which is the greatest number of any single year, but there is little evidence of growth in the numbers for the past six years, which are in order 234, 222, 239, 253, 216, 266. Doctorates in medicine are by no means the only ones that are "milled," for it was found that one unknown "university" in Indiana led all others, with a total of forty-five "Doctors of Philosophy." As this institution has no productive funds, and its total income from all sources was $4,500, the production of such doctorates at a cost of $100 a piece, not to mention the other degrees,

makes its position decidedly unique. Needless to say, *Science* has not included these forty-five "doctors."

Four-fifths of the degrees are conferred by seven universities, ranking in order as follows: Yale, Chicago, Harvard, Johns Hopkins, Columbia, Pennsylvania and Cornell. Just about equal numbers of degrees were awarded in science and in the "humanities," and what may seem astonishing to the scientist, there has been no appreciable gain by science on humanities in these past few years. Of particular interest to us, however, is the following table:

DOCTORATES CONFERRED IN THE SCIENCES.

	1898	1899	1900	1901	1902	1903	Total.
Chemistry	27	32	26	28	26	33	172
Physics	11	7	15	23	12	14	82
Psychology	18	15	9	13	8	16	79
Zoology	12	11	11	15	16	12	77
Mathematics	11	13	11	18	8	7	68
Botany	11	11	12	8	11	9	62
Geology	6	5	5	10	6	10	42
Physiology	4	1	4	1	8	8	26
Astronomy	3	2	4	5	2	4	20
Education	0	5	8	2	1	2	18
Sociology	0	5	3	3	4	2	17
Paleontology	0	4	2	1	0	2	9
Bacteriology	0	1	1	1	1	3	7
Anthropology	2	0	2	1	0	1	6
Anatomy	0	0	0	1	0	4	5
Agriculture	0	0	0	0	2	2	4
Engineering	0	0	0	1	0	3	4
Mineralogy	0	2	0	0	1	1	4
Pathology	0	0	0	0	0	3	3
Meteorology	0	1	0	0	0	0	1
Total	105	115	113	131	106	136	706

Here there is shown a most gratifying increase in the degrees in medical science. Physiology has graduated sixteen doctors in the last two years, against ten in the four years preceding. Of seven degrees in bacteriology three were given this year, while four of five degrees in anatomy were also given this year. Pathology makes its first appearance in the list with three degrees, although from a perusal of the titles of all the doctorate theses in science it seems that two of the three are really in bacteriologic subjects. This growth of degree-giving in those biologic sciences most intimately related to medicine is to be attributed to the growth of the spirit of a higher medical education, and is one of the encouraging signs of the times.

That anatomy and pathology have not been taught before in a way that might lead to graduate students taking them up as branches to be followed through the long stretches of labor that are required for the doctorate is regrettable, but that they are now considered as full departments of university work marks a much desired progress in medical education.

REMARKABLE FECUNDITY.

It is stated by one of our British contemporaries that a petition has been presented to the Italian government for a pension in favor of Signora Magdalena Grametta, who during twenty years of married life has been the mother of sixty-two children—fifty-nine boys and three girls. The details are not given, but before one would care to estimate the value to the state of such hyperfecundity, it would be interesting to know how many of these children survived. If the example were to be extensively followed, Malthusian ideas would undoubtedly become popular. The fact is an interesting one, however, in view of the allegations that are made as to the decreasing fecundity of the race in some countries. There seems to be no such defect in Italy, at least in exceptional cases.

KOCH'S RECENT EXPERIMENTS ON BOVINE TUBERCULOSIS.

Koch's experiments on the immunization of cattle against tuberculosis, which have been carried on for two years past, are reported by Neufeld.[1] The results of these experiments, the latter asserts, confirm Koch's statement of the non-identity of human and bovine tuberculosis, in fact, give the key to immunization research. It was possible in animals which were only capable of being affected by one toxin to produce immunity to this toxin by previous treatment with the other. The experiments were made with goats and asses, and later carried on in cattle. Some curious results in regard to the toxic dose of extract of tubercle bacilli were noted, but these will be described more fully in the abstract of the paper to be given in our next number. They find it impossible to produce immunity in guinea-pigs. The problem of producing immunity in man is somewhat different, but the results of these experiments are hopeful in their indications. The article is an interesting one and will undoubtedly receive considerable attention.

THE BRAIN WEIGHT OF THE JAPANESE.

It is not very long since someone stated, and the statement was generally quoted by the daily press, that the Japanese possessed the greatest brain weight of any modern race, and the natural inference was drawn that they would in time show their mastery. We have had few accurate data on which to base such a statement, and the one made may be taken as not specially authoritative. Recently, however, Professor Taguchi has been studying the brain weight of the Japanese and has given figures of the examination of some 597 subjects, which figures are analyzed by Dr. E. A. Spitzka in the last issue of *Science*.[2] Spitzka finds by these statistics that the Japanese certainly do show very respectable brain weights. He has used Professor Taguchi's data as to the relation between brain weight and stature, and, while the methods of tabulation differ to some extent, he finds that they correspond very closely with the figures given for the Germans, and are a little less than those given for the Szechs, as reported by Matiegka from some 306 specimens examined. Calculating also the number of grams per centimeter of the stature, the relative brain weight is about the same in the races mentioned, and only in the very small Japanese individuals is the ratio high. The relation of brain and body weight is not a reliable method, as Spitzka points out, since the mode of death and other factors materially influence the statistics. The figures seem to show that the brain of the Japanese grows more slowly in infancy and early youth than it does in the European, but the adult brain would compare favorably with that of the European of the same stature, and may be shown to be superior in this

1. Deutsche Med. Wochen., Sept. 10, 1903.
2. Science, Sept. 18, 1903.

respect to other races of the same general stature. Spitzka suggests that the facts are not of a little significance in relation to the recent progress of the Japanese.

SUICIDE IN THE UNITED STATES.

THE JOURNAL has previously noticed the communications published by Mr. Frederick Hoffman of the Prudential Life Insurance Company in the *Spectator* on the subject of suicides in the United States. In that journal, August 27, he gives a review of the suicide records of fifty of the principal cities in this country for 1902, with a comparison with the ten years preceding—1892 to 1901, inclusive. The record shows an increase in the rate during the year in twenty-eight towns, a decrease in twenty-one, and in one small town only was the ratio unchanged. The total gives the decided increase of from only twelve in 1890 to over seventeen per 100,000 of the population. Another table shows that the suicide rate has increased during the past thirteen years from twelve per 100,000 in 1890 to 1902. The gradual progressive increase would indicate that a still higher ratio may be reached in the future. To still further illustrate the importance of the subject Mr. Hoffman tabulates the suicides in New York City from 1804 to 1902, showing a marked increase during the last twenty years, though previous to that time there had been a fall which was quite marked between 1842 and 1868. The suicide rate during the first quarter of the century was much higher than during the second, while in the last one-half it has gone far beyond the earlier figures. What these figures indicate is perhaps a subject for some speculation; the great increase of urban population, the vast influence of the foreign element in our population, many of them coming from countries where suicide is much more prevalent than here, and the increasing stress of modern life and the arduousness of its conditions must all have their effect. They also show that in time of great national excitement, as during the 60's, there may be a decided fall in the suicide ratio to be made up for afterward, possibly as the later results of the special form of stress at that time. The figures Mr. Hoffman gives, as stated, are from fifty selected cities, probably those in which the suicide statistics were most available and most reliable. Still the omissions of such places as San Francisco, Denver and Kansas City are notable, and probably may have some influence on the general ratio. A large number of smaller towns are not included in the list, though fully as important and as large as some that are included. Taking it altogether, however, the statistics probably give us a fair showing as to the suicide ratio and its variations in the United States.

A CLERGYMAN'S DEFENSE OF ANIMAL EXPERIMENTATION.

While a few clergymen have committed themselves to the side of antivivisection, especially in Great Britain, there are many others of all churches who take the rational, and not the sentimental and pseudo-humane, view of the subject. Among the latter may be mentioned the Right Rev. Mgr. J. S. Vaughan, one of the most prominent prelates of the Roman Catholic Church in Great Britain. It is unnecessary for any one to bring out new arguments in favor of vivisection, but Monseigneur Vaughan puts the case, in a recent communication to an English periodical, the *Humane Review*, in a way that ought to be convincing. He says:

> Here is, let us say, an ordinary good-natured and able physician whom we will call Dr. X. His whole aim and object is to diminish pain and to allay suffering. It is not in his power to destroy it, therefore he directs his efforts to alleviate it. He knows that men are by far the most sensitive of sufferers. He knows that they are subject to certain painful diseases. He has good reason to think that a certain treatment would bring great relief, and perhaps even produce a cure. But his reasoning may be defective, and he can not ascertain with any degree of certainty whether his opinion be well founded unless and until he can test his theories by actual experiment. That is to say, he must actually apply the remedies. It is essential that he should make the experiment on a living organism of some kind. But on whom? Well, there are but two classes of creatures to choose from. He must make it either on a human being or else on a beast; either, let us say, on a sick child or on a rabbit. The antivivisectionist objects to all experiments on animals, and in effect answers, "The experiment must be made on the sick child, not on the rabbit!" And this is why we call the antivivisectionist cruel. We, on the contrary, hold that the experiment should be made on the rabbit or other beast, and not on the unfortunate sick child. Yet, on that account we are called cruel. Our reason for maintaining this view is, first, because the beast is less sensitive to pain. Secondly, because its loss of life, should the experiment prove abortive, is of far less consequence. Thirdly, because the child is our own very flesh and blood, and a member of our great human family, and has immeasurably greater claims on our pity. Fourthly, because God has given men domain over the beasts of the field.

The antivivisectionists have elevated their zoöphily above Christianity, and it is a satisfaction to have a champion of Christianity whose views of the scriptural side of the subject can not be questioned against this modern Brahminical nonsense which has nothing Christian in it. It is inhumane in its very essence. While God, as we are told by the Savior, takes account of every sparrow that falls, yet we are told in the same connection: "Ye are of more value than many sparrows"—a passage we fear the antivivisectionists would like to have blotted out of Holy Writ.

Medical News.

ILLINOIS.

Personal.—Dr. Everett H. Butterfield, Ottawa, has been reelected physician of La Salle County.——Dr. Homer A. Millard, Minonk, sailed for Germany, September 15.

Faith Cure Case Remanded.—The Appellate Court, fourth district, has rendered a decision in the case of the Board of Health of Illinois versus S. E. Peden of Centralia, who was charged with practicing medicine without a license, and who was tried twice in Marion County. He was first tried and acquitted before a justice of the peace, then before the County Court, with the same result. The State Board of Health then took the case to the Appellate Court, which reversed and remanded it on account of defective instructions, and it will go back to the County Court for another trial. Peden's defense is that his practice is simply laying on of hands, which he contends is in no sense the practice of medicine.

Chicago.

University of Illinois Medical Department.—The regular session of the College of Physicians and Surgeons opens October 1 with an address by Dr. George P. Dreyer.

Fewer Deaths.—The deaths for the week ended September 19 were fewer than in that preceding, being 496, against 504. The death rate per 1,000 per annum was 12.97 per 1,000,

against 13.94 for the week before, and 13.83 for the corresponding week of 1902.

Rush Medical College.—The graduating exercises will be held October 6. The address will be delivered by Prof. Charles Scott Sherrington, the eminent physiologist of Liverpool.——Dr. Frank W. Lynch, formerly of the department of obstetrics and gynecology at Johns Hopkins University, will assume his duties on the staff of the college on October 5.

Personal.—Dr. A. E. Halstead has been appointed attending surgeon to St. Luke's Hospital.——Dr. and Mrs. Daniel R. Brower, Jr., sailed for Europe, September 22, on the *Kaiser Wilhelm II.*——Dr. James Nevins Hyde has returned after a summer on the coast of Maine.——Dr. and Mrs. R. D. Macarthur have returned from Old Orchard Beach.——Dr. E. Fletcher Ingals, who has been rusticating in Connecticut for the last two months, will return to Chicago to-morrow.

Examination for Assistant Bacteriologist.—The Civil Service Commission of Chicago will hold an original entrance examination for the position of assistant bacteriologist of the health department, Oct. 22, 1903, in room 400, City Hall. The salary attached to the position is $1,000. Those taking the examination must have been residents of Chicago for one year, and must file application prior to the examination. Application blanks may be procured by addressing T. J. Corcoran, secretary Civil Service Commission, room 400, City Hall.

IOWA.

Withdraws Resignation.—Dr. Lewis Schooler, Des Moines, has reconsidered his action taken a short time ago and has resumed the chair of surgery in the medical department of Drake University.

Physician Assaulted.—Dr. Edgar L. Bay, Eddyville, while returning from a call in the country, was struck on the head and stunned by an unknown individual, whose motive is supposed to have been robbery.

Colleges Begin Work.—Keokuk Medical College began its work for the year, September 15, with an address by Dr. Alonzo B. Hughes.——Sioux City College of Medicine opened September 8 with an address by Dr. Charles M. Wade.

Many Not Registered.—The county recorder of Woodbury County has discovered that from 10 to 20 per cent. of the practitioners of medicine in that county have not registered their certificates with the county recorder, as required by law.

Reality was Disappointment.—Because an enterprising advertising practitioner of Des Moines used a picture of the state house on his circulars and pamphlets, thereby creating the impression that his sanatorium had five gilded domes and countless windows, he has been indicted on the charge of obtaining money under false pretences.

MICHIGAN.

Press Committee Appointed.—The Wayne County Medical Society has decided to appoint a press committee, whose duty it shall be to prepare the news of the society in digestible form for the lay press.

Personal.—Dr. Robert E. Cooper, Plymouth, has typhoid fever, and has been removed to Harper Hospital, Detroit.——Dr. Jerry M. Jones, Bay City, charged with failure to report communicable diseases, has been discharged.

Communicable Diseases.—Meningitis was reported present during August at 3 places; whooping cough at 36 places; measles at 46 places; diphtheria at 49 places; smallpox at 61 places; scarlet fever at 92 places; typhoid fever at 127 places; and consumption at 226 places. Meningitis was reported present at 2 places less; whooping cough at 4 places less; measles at 39 places less; diphtheria at 6 places less; smallpox at 20 places less; scarlet fever at 4 places less; typhoid fever at 48 places more, and consumption at 10 places more, in August, than in the preceding month.

August Mortality of Michigan.—The total number of deaths in Michigan during August was 2,800, an increase of 147 over the preceding month. The death rate was 13.3 per 1,000 per annum. There were 688 deaths of infants under 1 year, 211 deaths of children from 1 to 4 years, and 697 deaths over 65 years. Important causes of death were as follows: Tuberculosis, 187; typhoid fever, 44; diphtheria, 37; scarlet fever, 16; measles, 2; whooping cough, 37; pneumonia, 100; diarrhea and enteritis, under 2 years, 386; cancer, 157; accidents and violence, 240, including 32 deaths from drowning and 7 deaths from lightning. There were 2 deaths from smallpox.

Comparative Morbidity.—For August, compared with the preceding month, diarrhea, cholera morbus, dysentery, cholera infantum, typhoid fever and inflammation of bowels were more prevalent; and pneumonia, measles and inflammation of brain were less prevalent. For the same month, compared with the average for August in the 10 years previous, pleuritis, tonsillitis, diphtheria, scarlet fever and smallpox were more than usually prevalent; and diarrhea, cholera morbus, dysentery, consumption, cholera infantum, intermittent fever, inflammation of bowels, remittent fever, erysipelas, inflammation of brain, and meningitis were less than usually prevalent. Diarrhea, dysentery, cholera infantum and cholera morbus are usually most prevalent during July, August, September and October, but these diseases were from twenty-six to forty-five per cent. less prevalent than usual in the August just passed.

MISSOURI.

Failed to Register.—The first fruits of the crusade against unregistered physicians in St. Louis were apparent when 85 practitioners were cited to appear before Judge Tracy, on September 18, to explain why they had not complied with the law.

Results of Flood.—Since August 1, 30 deaths from typhoid fever have been reported in Kansas City, and about 75 cases are under treatment in the various hospitals of the city. It is impossible to estimate the additional number of patients under treatment at their homes.

Personal.—Dr. Horatio S. Jones, Kansas City, was recently thrown from a cable car and injured his spine.——Dr. Lemuel T. Hall, superintendent of State Hospital for Insane, No. 4, Farmington, has resigned, and Dr. Frank L. Keith has been appointed temporarily to fill the position.——Dr. John M. Doyle, St. Joseph, who was operated on for appendicitis, September 9, is securely convalescent.

College Year Opens.—Ensworth Medical College, St. Joseph, opened for its twenty-eighth year, September 2.——Central Medical College, St. Joseph, held its tenth annual opening exercises, September 7. Addresses were made by Dr. Thompson E. Potter, president, and Dr. O. Beverly Campbell.——Medico-Chirurgical College, Kansas City, opened its seventh annual term, September 7, with an address by the dean, Dr. George O. Coffin.——Kansas City Medical College began its thirty-fifth year of work on September 9.

NEW JERSEY.

Medical Staff Want Interne.—The board of governors of North Hudson Hospital have decided that an interne should be secured for the institution at a salary of $200 a year. One half of this amount the medical staff has agreed to pay.

New Eye and Ear Infirmary.—A new building to cost $50,000 will be ready next year for the Newark Charitable Eye and Ear Infirmary. The building is to be fireproof, will accommodate 30 in-patients, and an unlimited number of dispensary cases.

Personal.—Dr. John C. Applegate, Bridgton, has moved to Philadelphia, where he has accepted the chair of obstetrics in Temple Medical College, and the position of obstetrician to the Samaritan Hospital.——Dr. Richard R. Rogers, Trenton, on the occasion of his eightieth birthday, was tendered a reception by 300 of his friends, and was presented with a reclining chair by the members of the city board of health.

NEW YORK.

Cornerstone Laid.—Bishop McDonnell laid the cornerstone of the new hospital being erected by the Little Sisters of the Order of St. Dominic, at Jamaica, September 17.

Temple Again.—Franklin Stewart Temple, who attained unenviable notoriety by reason of his connection with "Antonius" the faker of Buffalo, has visited Jamestown, and certain individuals who had been under his care there are now asking the police to try and locate the healer.

Personal.—Dr. Augustus G. Pohlman, Buffalo, has been appointed assistant professor of anatomy in Johns Hopkins University, Baltimore.——Dr. William L. Russell, Willard, has been appointed Medical Inspector of Institutions for the Insane.——Dr. Richard H. Hutchings, assistant physician at the St. Lawrence State Hospital for the Insane, Ogdensburg, has been appointed superintendent, vice Dr. William Mabon, resigned.

New York City.

Sold Free Antitoxin.—Dr. Anton M. Lacina, charged with selling antitoxin furnished him without charge for use of the poor, pleaded guilty and sentence was suspended.

Suicide on the Increase.—In 1902 there was 772 suicides in Greater New York. Ten years ago the number was about 50 per cent. less. Of the suicides 196 were women, 73 of whom were native-born. In Manhattan and the Bronx the suicide rate per 100,000 has increased from 14 to 22 in the last ten years.

The New Gouverneur Hospital.—Plans for the new hospital have been filed. They provide for the erection of the additional west wing to the present five-story and basement main building, also for a one-story rear extension into the courtyard, and for the erection of a two-story ambulance station, with a stable annex. The new building, when finished and furnished, will cost the city about $500,000. The additional wing and extension are to cost $250,000 and the ambulance station will cost an extra $25,000.

Buffalo.

Warning to Milkmen.—The health commissioner has sent each milkman and dairyman of Buffalo a warning note on milk adulteration and adulterants. Any milkman who is guilty of adulterating milk or cream will immediately have his license revoked.

Personal.—Dr. Matthew D. Mann has returned from the lake shore.——Dr. Irving P. Lyon has returned from the Adirondacks.——Dr. Dewitt Sherman has returned from Bar Harbor, Maine.——Dr. Irving M. Snow has returned from abroad.——Dr. John Woodruff is in the Bermudas.——Dr. Frederic Zingsheim is seriously ill with typhoid fever.——Dr. Gustav A. Hitzel has returned from Atlantic City.

Another Eddyite Death.—A girl of 14 died of diphtheria without medical attendance, having been treated by an Eddyite, and in order to comply with the law Dr. J. L. McAdam was called in shortly before death. He refused to issue a certificate, and referred the case over to Health Commissioner Greene, who has given it, with all the facts bearing on the case, into the hands of the district attorney for prosecution.

August Mortality.—The monthly report of the department of health for August shows an annual mortality rate of 16.98 per 1,000. Among the principal causes of death are: Consumption, 37; cerebrospinal meningitis, 4; cholera infantum, 57; diphtheria, 14; measles, 13; typhoid fever, 9; debility, 35; cancer, 26; apoplexy, 19; valvular heart disease, 13; pneumonia, 20; appendicitis, 11; cirrhosis of the liver, 8; diarrhea, 14; enterocolitis, 12; gastroenteritis, 15; nephritis, 23, and violence, 46. The total deaths for August, 1903, were 538, as compared to 520 for August, 1902.

OHIO.

Adjudged Insane.—Dr. Patten McConnell, Arnold, has been adjudged insane and ordered to be committed to the State Hospital.

Personal.—Dr. Francis M. Smallwood, Chillicothe, was stricken with paralysis while crossing Saginaw Bay.——Dr. Ernest C. Voltz, Chili, attempted suicide by poison recently, but an overdose saved him.

The Reeve Anniversary.—The Sisters of St. Elizabeth Hospital, Dayton, gave a dinner to the staff, September 7, in honor of the twenty-fifth anniversary of Dr. John C. Reeve's services as chief of staff.

In the Hands of the Law.—O. P. Cooper was fined $100 and costs at Uhrichsville for practicing medicine without a license.——Dr. Maurice Smith, Massillon, was recently fined $10 and costs for failing to report births and deaths as provided by law.——Warrants have been issued at the instance of the Lorain County Medical Society for the arrest of Mrs. A. Chapel, Mrs. Eva Sokol and Mrs. Mary Miskien, charged with practicing midwifery without license.

College Openings.—Miami Medical College will open as a coeducational institution, October 1.——Ohio Medical University, Columbus, opened September 16; Dr. James U. Barnhill presided.——The forty-eighth year's work of Starling Medical College began with a clinic by Dr. Starling Loving, September 16.——Cleveland College of Physicians and Surgeons opened for the year with an address by Dr. Samuel W. Kelley, on "Medical Students I Have Known."——Toledo Medical College opened for the year on September 24.

PENNSYLVANIA.

Philadelphia.

Child Labor.—Believing that the child labor law is grossly violated in the city, Director of Public Safety Smyth has instructed police lieutenants to ascertain where children under fourteen years of age are employed in stores, factories and mercantile places.

New Building Dedicated.—October 4 formal exercises will mark the dedication of the three new buildings of the Jewish Hospital. These buildings are the Eisner Home for Nurses, already occupied; the Loeb Memorial Operating Building, and the Guggenheim Private Hospital. The latter two will be ready for use within a few weeks after their dedication. The hospital grounds comprise twenty-two acres situated on the Old York Road, containing in all fourteen buildings.

Colleges Open.—Jefferson Medical College was formally opened September 24, with an address by the president of the board of trustees, Hon. William Potter.——All the departments of the University of Pennsylvania, including the medical, were opened September 25. Provost Harrison made an address.——The Medico-Chirurgical College will open September 28, Dr. Geo. H. Meeker, professor of chemistry, delivering the opening lecture.——Class work was resumed at the Woman's Medical College, September 23, there being no formal opening address.

The Typhoid Situation.—New cases of typhoid fever numbering 82 were reported for the week ended September 19, a decrease of 53 from the previous week. Seventy-eight cases have been reported from the Twenty-first ward since August 1 The very large number of cases in this section has led to a special investigation of the cause by Chief Abbott of the bureau of health, with the resulting report that sewage conditions were in many places bad, but that, of the victims in this section, over fifty per cent. were found to have purchased their milk from one dealer. On further investigation, it was found that within the last few months three members of the family of this dairyman had had the disease. On the reasonable assumption that the milk handled by the dealer had been accidentally contaminated, he was ordered to discontinue the sale of milk until thorough disinfecting measures had been carried out.

Segregation.—A handsome and roomy brick and cement building has just been erected in the Philadelphia Hospital grounds in which are to be placed the families of patients suffering from contagious diseases, except smallpox. The patient himself will be taken to the Municipal Hospital, while his relatives are thoroughly sterilized in the new building. There are fifty rooms in the house, each ten feet square, for the accommodation of the occupants, and the receiving ward is separated from the living rooms by porcelain doors. The number of rooms allotted to a family will vary in accordance with its size, but all the families brought there will be made comfortable at the city's expense during the period of their detention. Meanwhile the home of the family will be in the hands of the board of health, and formalin gas diffused through the house for twenty-four hours. In case the patient is suffering from smallpox his family will be taken to the Municipal Hospital with him.

Phipps Institute Lectures.—The Henry Phipps Institute for the Study, Treatment and Prevention of Tuberculosis has arranged for the coming fall and winter series of lectures by well-known physicians on the various phases of tuberculosis. Some of these lectures will be more or less popular in character and all will be free to the public. The auditorium of the Witherspoon Hall at Juniper and Walnut streets, Philadelphia, has been selected for the purpose, having a seating capacity of nearly twelve hundred people. A cordial invitation is extended to the profession in general to attend these lectures. The first lecture will be given by Dr. E. L. Trudeau of Saranac Lake, New York, during the last week in October, his subject being "The History of the Development of the Tuberculosis Work at Saranac Lake." The following additions to the staff have been made: Dr. M. P. Ravenel has been appointed assistant medical director and chief of the laboratory; Dr. E. A. Shumway, ophthalmologist, and Dr. J. F. Wallis, dermatologist.

Assistant Chiefs Appointed.—Each visiting physician to the Philadelphia Hospital has recently been given the privilege of sending, at times, a representative to look after his wards. Following are the assistants appointed, known as assistant chiefs; Assistant physicians—Drs. B. F. Stahl, Norman G. Gyn, John Da Costa, John H. Cruice, R. H. M. Landis, William

Pepper, H. C. Wood, Jr., J. S. Evans and J. N. Henry; assistant surgeons—Drs. W. P. Hearn, M. B. Miller, R. H. Loux, M. P. Warmouth, J. B. Carnett, D. G. Metheny and T. T. Thomas; assistant obstetricians—Drs. Stricker Coles, J. C. Hirst, P. Brook Bland, E. P. Bainbridge, W. R. Nicholson, M. W. Griscom, and A. P. Berg; assistant neurologists—Drs. A. Gordon, J. W. McConnell, L. C. Peter, D. J. McCarthy, T. H. Weisenberg, and H. Carncross; assistant ophthalmologists—Drs. E. A. Shumway, J. C. Knipe, W. M. Sweet and A. R. Renninger; assistant dermatologists—Drs. E. J. Stout, S. H. Brown and H. J. Smith; assistant pathologists—Drs. John Funke, G. McConnel and R. M. Pearce; assistant laryngologists—Drs. Ralph Butler, M. W. Hinkle and W. G. B. Harland; assistant orthopedic surgeons—Drs. T. J. Rugh and Edward B. Hodge, and assistant pediatrists—Drs. A. H. Graham, Harry Lowenberg, Charles A. Fife and J. H. McKee.

UTAH.

New Isolation Hospital.—A new smallpox house has been erected at Salt Lake City to replace the building which was burned a short time before.

Fire in Hospital.—Heroic work by nurses and attendants prevented loss of life in a fire which damaged the Keogh-Wright Hospital, Salt Lake City, to the extent of $10,000, September 15.

August Vital Statistics.—During August 72 deaths were reported in Salt Lake City, equivalent to an annual death-rate of 11.52 per 1,000. During the same period 134 births were reported. Typhoid fever was multiplied seven-fold, 75 cases being reported during the month, with 2 deaths.

School Children's Diseases and Deaths.—For the year 1902-1903 Dr. Eugene W. Whitney, Salt Lake City, medical inspector of city schools, reports 114 cases of smallpox, 142 of diphtheria, and 110 of scarlet fever. Diphtheria caused 29 deaths; typhoid fever, meningitis and respiratory diseases, each 6; digestive and heart diseases, each 5; accident 3, and scarlet fever, 2. Defects revealed by inspection were: defective teeth, 260; defective vision, 284; enlarged tonsils, 128; mouth breathing, 25, and vermin, 52. Only one out of 45 had any eye disease.

GENERAL.

Plague in Manila.—Bubonic plague is reported in Manila's environs to the number of 100 cases and 80 deaths. Cholera is prevalent in all parts of the islands.

Guest of the Section on Ophthalmology.—Dr. Simeon Snell, Sheffield, England, has accepted the invitation to be the guest of the Section on Ophthalmology of the American Medical Association at the next session—Atlantic City, June 7 to 10, 1904. This news will be appreciated by ophthalmologists.

Hawaii Wars on Mosquitoes.—The endeavor to rid Honolulu and vicinity of the mosquito scourge is being pushed. Stagnant water is being removed and the edges of all streams and ponds are being freed of vegetation to enable the fish to feed there. Public meetings are held to instruct the people in prophylaxis.

Much Yellow Fever in Mexico.—At the city of Linares, Mexico, are reported 600 cases of yellow fever. The mortality is severe. The disease has not yet reached Monterey. Quarantine is strict. Monterey protests against quarantine, but the United States officials are determined to be on the safe side. Linares is almost isolated and business is nearly at a standstill.

Smallpox on the "Sherman."—A case of smallpox was diagnosed, August 1, on the transport *Sherman* at Manila. The ship was at once disinfected and proceeded on her way to Mindanao. The ship surgeon considers the source of the infection was a suit of clothes which was issued to a private in the Seventeenth Infantry in the state of Washington shortly before the transport sailed. The man wore the uniform to make a call on a young woman who had smallpox, and then packed away the uniform till he reached Manila. Here he used it again and received the infection.

CANADA.

The Opening of the New Medical Buildings of Toronto.—The first session of the newly amalgamated medical faculties of Toronto and Trinity will begin October 1, when the fine new medical buildings will be opened.

Montreal General Hospital.—At the regular quarterly meeting held last week, a memorial to the late Dr. Wyatt Johnston was discussed and referred to the committee of management. The ordinary receipts from Jan. 1 to June 30, 1903, amounted to $56,540, and the expenditures to $50,728. In addition to the ordinary income there has been received during the six months legacies amounting to $18,475. Improvements have been made to the extent of nearly $3,000.

Provision for Clinical Study of Infectious Diseases in Toronto.—The medical health officer of Toronto, Dr. Charles Sheard, who is also professor of preventive medicine in the amalgamated medical faculties of Toronto and Trinity, is making arrangements whereby fourth year students in medicine will be given clinical instruction in infectious and contagious diseases. This is a step which medical students at Toronto will very much appreciate as heretofore students have had to go out into practice without ever having seen a case of scarlet fever or diphtheria.

Lady Minto's Hospital Scheme.—Lady Minto addressed a meeting of the citizens of Vancouver, B. C., September 10, in which she outlined her cottage hospital scheme. Learning of the long distances many injured persons had to journey before securing medical aid, the plan was conceived that cottage hospitals established at convenient centers would do much toward relieving this suffering and distress. The Lady Minto Cottage Hospital Fund was started and rapidly grew until at the present time eleven of these hospitals have been established, scattered from the Atlantic to the Pacific oceans. In British Columbia there are three. An endowment fund yielding $5,000 annually is looked for. Already $100,000 has been received from Toronto, Ottawa and Montreal, and but $25,000 more is required.

Vaccinations in Montreal.—The Montreal Health Department has just completed a report of much interest to the citizens of that place. It shows an enormous increase in the number of vaccinations in the past few years. In 1902 the total number of vaccinations was 96,796, divided as follows: In schools, 52,301; in factories, 44,495. Another report shows the vaccinations by years since 1878, in which year there were 3,273. In 1885, when the smallpox was epidemic there, the number was 26,150. In 1895 the number was 2,872; in 1901 the number was 36,976. A very surprising and instructive table, "Smallpox vs. Vaccination," shows that out of 503 cases of smallpox, no less than 443 were never vaccinated. The reason for there being such an enormous increase in vaccinations for 1902 was on account of the compulsory by-law requiring factories, railways, schools and public institutions to exact vaccination certificates from those they employ or receive.

FOREIGN.

Study Tropical Diseases in Africa.—Drs. Dutton, Tod and Christy, of the Liverpool School of Tropical Medicine, sailed from Southampton, England, September 18, for Africa to study the sleeping sickness and other tropical diseases in the Congo River region.

Declining Birth Rate in Prussia.—In 1876 the birth rate per 1,000 in Prussia was 40.9, while in 1901 it had declined to 36.52. That of Berlin has dropped from 46 in 1876 to 26.68 in 1901. In 349 districts the birth rate has constantly declined, while in 210 it has increased. The latter are country districts and all in the west.

Cancer Asylum at Moscow.—This new institution for cancer research—the first of its kind in Russia—was duly completed and opened September 1. It has accommodations at present for sixty patients, and will soon receive a hundred. The expense of construction was nearly $150,000, given by a wealthy Moscow merchant. The building contains operating rooms and an amphitheater for demonstrations.

International Congress for School Hygiene.—This congress will be held at Nuremberg, April 4 to 9, 1904. Communications must be sent to the secretary, Dr. Paul Schubert, Nuremberg, before December 15, 1903. On account of the limited accommodations of this quaint old city those intending to attend the congress are requested to notify Dr. E. Stich as soon as possible in order that quarters may be reserved for them. The fee for the congress is $5, to be paid to the treasurer, Mr. Emil Hopf, 17 Blumenstrasse, Nuremberg.

Campaign Against Malaria in Italy.—The *Riforma Medica* states that quinin was administered regularly to 923 persons in the hotbeds of malaria during 1902, and only 44, that is 4.6 per cent., contracted malaria and the cases were mild. In the corresponding groups of persons not taking the quinin, but otherwise under the same conditions, from 18 to 82 per cent

contracted the disease, an average of 50 per cent. It adds that it has been officially calculated that at an expense of $8,000,000 a year it might be possible in the course of ten years to banish the last case of malaria from Italian soil.

Campaign Against Charlatans in Germany.—Magdeburg, Germany, has had 29 suits against charlatans in the courts during a single year recently. The charge was swindling in 10, personal injury in 2, death from criminal practices in 1, assumption of an unjustified title in 3, and infraction of the police regulations in the remainder. The Prussian and other states have decided to hold the advertisement editors of the press responsible for charlatan ads which promise cures impossible to realize or advertise articles known to be injurious. The editor of the *Osnabrücker Tageblatt* was recently summoned and fined $1.25 on two counts. One was for publishing an ad which lauded a truss without a spring, under the heading "No more hernias." The other advertised a certain eye water for weak eyes claiming that glasses would not be needed longer after two to four weeks' use of the water. The cases were appealed and the higher court confirmed the constitutionality of the decisions. The Carlsruhe board of health has issued a warning to the public in regard to a powder advertised to cure epilepsy in three days. It stated that the powder contained artemisia, which used to be a popular remedy against hysteric convulsions, but is powerless in genuine epilepsy, and that the price charged is extremely exorbitant.

Ankylostomiasis in Western Europe.—The French authorities have been conducting investigations which show that ankylostomiasis has not yet invaded France. Belgium is affected and energetic measures have been taken to stamp out the infection which was first imported into Germany and Belgium by the workmen returning from the construction of the Saint-Gothard tunnel in Switzerland. The Belgian government announced that it did not have the means to undertake prophylactic measures, and the city council of Liège, the point most affected, assumed the task in 1899. It appropriated $4,000 a year for examinations and small pensions to be given to affected persons, hoping in this way to induce the miners to declare the presence of the parasites more promptly. In addition to this, a special dispensary and hospital was established last year for those affected. This not only serves to keep the patients under surveillance during treatment, but is valuable as a means of isolating them and sterilizing the dejecta which otherwise would be a menace to others. The course at the hospital is also a training in hygienic and prophylactic measures so that the discharged patient is able to warn and instruct his comrades. The latest report from Bochum in Germany states that 50,000 out of the 250,000 miners there are affected with the parasite.

LONDON LETTER.

Report of the Commission on Dysentery and Typhoid Fever in the South African War.

In August, 1900, a commission consisting of Colonel Notter, Lieutenant-Colonel Bruce and Dr. W. J. R. Simpson was appointed to investigate the outbreak of dysentery and typhoid fever, which occurred in the South African War. It has just issued a valuable report. To Colonel Bruce was allotted the laboratory work. Regarding the various organisms held to be causative of dysentery his conclusions are mainly negative. He found no relation to amebæ or other species of organism nor any relation between dysentery and typhoid fever. Dr. Simpson fully describes the outbreaks of these diseases. He shows how the very insanitary environment as regards drainage, soil, disposal of excreta, and water-supply furnished ample sources for their spread, and points out how the flies swarmed from the latrines to the nearest unprotected food supply. The total number of cases of dysentery was as follows: first year, 11,143, with 546 deaths, a percentage of 4.9; second year, 13,131, with 427 deaths, a percentage of 3.2. Of typhoid fever there were in the first year 15,655 cases, with 3,647 deaths, a percentage of 23.2; in the second year 15,463 cases, with 2,530 deaths, a percentage of 16.3. The comparative absence of the fatal dysentery which usually attacks armies in the field was probably due to the excellent food arrangements, the soldiers obtaining their rations perfectly fresh and thoroughly cooked. The chief cause of dysentery was probably the drinking of surface water, especially the water of rivers, such as the Orange and Modder, holding in suspension a large amount of organic matter. Dr. Simpson points out a defect of organization: there was no specially trained and organized executive by which the recommendations made to the commanding officer of the various units could be carried out. This was the result of the persistent ignoring, as far as possible, of the medical corps by the military authorities. Dr. Simpson recommends that the medical corps should be divided into (1) a medical branch and (2) a health branch, and that the latter should be specially trained in preventive medicine.

The Anti-Mosquito Campaign in Egypt.

Major Ross has received a report that the anti-mosquito campaign, commenced less than a year ago by the Suez Canal Company (referred to in THE JOURNAL) and carried out according to his instructions, has been remarkably successful. The town of Ismailia is practically free from mosquitoes, which only a short time ago were very abundant. Even mosquito nets can be almost dispensed with, and people can sleep without being bitten. Two marshy swamps on the northeast of the town have been filled up with sand and a third one will soon be dealt with. It will be drained by a pipe 22 cm. in diameter which will convey away the water. A gang of 180 men are employed in filling up pools, moving the coarse grass and undergrowth, and clearing the numerous small channels in connection with the main canal. When they first commenced operations they were worried by swarms of mosquitoes toward evening, but scarcely any are seen now. The statistics of malaria in Ismailia show a remarkable improvement. From January 1 to June 30 of this year there were only 3 cases in hospital, against 52 for the same period last year and throughout Ismailia there were 569 cases from January 1 to May 30 in 1902, against 72 for the same period of this year.

Report of the Royal Commission on the South African War.

This report, which has just been issued, may be regarded as the last word on the so-called "hospital scandals," which caused so much sensation during the war. It clearly shows that before the outbreak of hostilities the military authorities overruled the demand of the surgeon-general for more men. He represented to them that the medical establishment was not even equal to the requirements of peace. When the war broke out practically the whole of the Army Medical Corps, officers and men, was exhausted in supplying the First Army Corps, and in manning the base and stationary hospitals. When, therefore, the Second Army Corps followed, assistance had to be obtained from civilians. Altogether 8,500 men were sent out, but barely a quarter of these were trained Army Medical Corps men. The commissioners attempted to obtain an idea of the percentage of medical strength which a force in the field required. Professor Ogston, who had studied the statistics of modern wars, said that the Medical Department should form about 5 per cent. of the strength of a force, but Surgeon-General Jameson thought that under favorable circumstances 2½ per cent. was sufficient. This was the percentage adopted by the War Office before the war. Including voluntary and outside assistance the medical strength during the war seems to have been from 3 to 4 per cent. of the total forces. The difficulty was in a war conducted over so large an area to secure that the medical personnel should be distributed in accordance with the need of localities or occasions. The most notable example of failure in this respect was the outbreak of typhoid fever at Bloemfontein. One great defect was pointed out: the army surgeon in times of peace had very little opportunity of acquiring surgical experience. The British system was unfavorably contrasted with the German. In Germany the military hospitals are larger and better managed, and every army surgeon can apply at short intervals to be admitted to the practice of civil hospitals. It is believed that the recent sweeping reforms in the service will remedy these defects.

Correspondence.

Health Resorts—The Patient—Home and Resident Physicians.

HOT SPRINGS, ARK., Sept. 5, 1903.

To the Editor:—The number of people visiting health resorts increases yearly. Among them are those suffering from chronic ailments and whose search is strictly for health; in such cases the question arises, how and under what circumstances will the patient derive the greatest benefit? Without a doubt the attending physician at the patient's home has the key to the situation, and it is on this basis that I formulate my deductions.

Dr. James K. Crook, in an article read before the section on general medicine of the New York Academy of Medicine, May 20, 1902, stated that we have within our borders springs that equal and excel those of Europe, with the exception of the sulphated salines, yet this is a matter not generally known, and one to which but little attention has been given by the general worker in medicine. Frequently is it the case that after a patient has been a sufferer for a long time with some chronic malady that a change of climate, surroundings, probably the advisability of a stay at a health resort are considered, either by the patient, the physician, or by both. It is at this time that the physician's help is most needed, his knowledge of the case reinforced by the perusal of literature on health resorts should make him, not the patient, the dictator. The climate, natural advantages, conveniences, and any special virtues of a resort should be thoroughly inquired into and if literature on this subject is not at hand, correspondence with physicians at the contemplated resorts will elicit what is sought after.

Without entering into any detailed discussion I will try to formulate a few definite rules that will tend to give the patient the greatest and best results obtainable:

1. The home physician and the patient should consult on the advisability of visiting a health resort as carefully as the first consultation on the case.

2. The physician should designate the resort to which the patient is to be sent, but only after a careful review of the benefits to be obtained.

3. The home physician should then correspond with a physician residing at the resort chosen, stating the case and requesting any information that may be of value.

4. On sending the patient, he should be given a letter to some resident physician. The case history up to the time of the patient's departure should be concisely and accurately stated, citing advantages and failures of various treatments, any especial idiosyncrasies of the case, etc. This answers the purpose of a consultation for the good of the patient and will frequently prevent the loss of valuable time to the latter and avoid the retracing of work that has proven a failure.

5. The resort practitioner must strive in conjunction with the home physician, through the history sent him, to give the patient every advantage of Nature's resources.

6. When the patient returns, an accurate account should be sent to the home physician, giving full details, so the latter may be thoroughly acquainted with the treatment had while away.

7. The two physicians should work in conjunction on all cases during the patient's stay and the one principal point, the welfare of the patient, should never be lost sight of.

If the above rules were more carefully adhered to, fewer invalids would take it on themselves to seek for health at some resort chosen on a mere empirical basis. The resort physician would thus be placed in immediate contact with the case, and as the question of confidence in the former by the latter is of paramount importance, an advantage point is already gained, the value of which is unmeasurable. It would tend to place our resorts on a higher standard, and before the expiration of a great while the value of a perfect understanding for the good of the patient would be as well recognized here as abroad.

It is the duty of every physician to assist and strive for the welfare of his patients; why, therefore, if they insist and feel as though benefits might be derived elsewhere, does he allow them to go unrecommended and unprepared? The American Medical Association has gathered within its ranks many of the reputable physicians of this country; the present standard of requirement of admission should certainly be sufficient evidence of the good character and professional attainments of its members; every resort in this country is represented by some physicians affiliated with this Association, and the acquiring of the names is but a matter of a few days at most. We all owe our patients our best judgment, and what has been stated above is certainly not a shortcoming in that respect. WILLIAM F. BERNART, M.D.

218 Central Avenue.

The Commission Evil.

MILWAUKEE, Sept. 1, 1903.

To the Editor:—Owing to the vital question of professional ethics involved, the enclosed correspondence may be deemed worthy of reproduction in your pages.

H. V. WÜRDEMANN.

——, Aug. 19, 1903.

DR. H. V. WÜRDEMANN, Milwaukee, Wis.

Dear Doctor:—I have a male patient 58 years old coming to my office with inversion of both eyes, the disease has become very chronic (Right eye) the upper lid has five rows of displaced lashes and he has lost all power to open this lid. the left is not as bad and its seem to me there is shrinking of the conjunctiva from chronic disease, Especially trachoma The sight is fairly good of both eyes, now what in your opinion do you think it would cost him, and what per cent will you give me if I send you all the eye cases from out this way? The reason why I want to know about what it cost these farmers is so I can tell them beforehand to get the money ready, Yours Respt.

(Signed) ——

P. S. Let me hear from you soon.

MILWAUKEE, Aug. 24, 1903.

DR. ————.

My Dear Doctor:—Your letter of the 19th inst. received. On account of the two *business* questions raised in it, and as I have been approached in like manner before, I have taken some time to formulate a proper answer. I intend that this correspondence shall be published for the benefit of other young physicians who might ignorantly at some time raise the same question to their personal detriment.

From the description of your case I think that the eye condition is entropion of the lids, resulting from the cicatricial stage of chronic granular conjunctivitis (trachoma). Plastic operations on the eyelid will probably relieve the entropion.

It would not be fair to either patient or physician to give an estimate of the cost of the work without proper examination. As you well know, professional fees are regulated by several factors: Kind of services rendered, amount of time consumed and the financial standing of the patient. Thus there are no fixed fees for services; the only professional and legal requirements being that they be reasonable and such as are customary with physicians of the class to whom the consultant belongs. Customary office consultation fees in this country range from $5 to $25, depending on the standing of the consultant, as well as the above-named factors.

The above would be a sufficient answer to your letter were it not for your question: *"What per cent. will you give me if I send you all the eye cases from out this way?"* I take it for granted that you consider this question quite correct and honorable! I beg, however, to answer it curtly and completely:

The presumable reason why one physician refers a case to the care of another is that he is either unable or unwilling to give proper attention to the patient and sends him to the other's care purely for the patient's good and not as a business transaction.

The giving or acceptance of commissions by physicians (or other people) for sending patients to consultants is an unethical and dishonest act, which has not been tolerated by true physicians from the days of antiquity. It is *dishonest*, because the patient is deceived, and the collusion is more dishonorable than commission business between the doctor and druggist, which has long been frowned on by both the profession and laity. It is a *cowardly* proceeding if either of the doctors are afraid to let the patient know for what he is paying, that which he has an ethical and legal right to know. *The medical profession is not a trade*, and division of fees without the knowledge of the patient would be degrading the whole profession to the trade level.

I am not practicing medicine as a business, but as a profession, and while I am entitled to a fair fee for the knowl-

edge, time and labor expended on the case, I can not stoop to the tradesman's means of hiring drummers to get me patients. Your proposition would degrade you to a "hired man" or "barker" for the quack who might accept.

You may have, in some instances, spent time in caring for or in accompanying a patient to the consultant's office and felt delicate about submitting a bill for same—why—that is pure cowardice, the laborer is worthy of his hire!

On account of his financial condition your patient may not be able to pay the usual fee of the consultant or surgeon, yet you feel that you are entitled to some payment for such services as above stated. The matter is easily arranged; the patient has but to explain his circumstances and the consultant should be willing to reduce his fees so that the family physician may get some payment, but *all this must be done with full knowledge and consent of the patient.* I am always willing, when necessary on account of the financial condition of the patient, to reduce my bill enough, even to giving my services gratuitously to allow them to pay you, but I will not pay you a part of my fee because you are afraid to demand it of the patient.

In conclusion, I am willing to do any special work for you for what is a customary fee among specialists of my standing, for patients able to pay same; for others who can pay but little I am willing to do the work for the proportion of the usual fee they may be able to give me after paying for your services; and in cases unable to pay anything, I will cheerfully do the work without monetary recompense on your recommendation; but I will not hire any medical "barkers" to drum up trade. My strongest reasons, aside from the ethics of the case, for refusing your request is that I value the esteem of the general profession more than a business which I could not retain, if I abandoned the customs and ethics followed since the days of Galen, yea, even from those of Æsculapius. Yours very sincerely, H. V. WÜRDEMANN.

The Visiting Physician in Berlin.

BY DENSLOW LEWIS, M.D.
CHICAGO.

It has been suggested that I give a little common sense advice which may help the medical man in Berlin to utilize to the best advantage the exceptional clinical material that is there placed at the disposal of every student. I have just returned from a year's residence at that university, and at former periods of my life I have been privileged to study four years in other European cities. This experience may not entitle me to speak by the card, but at all events it authorizes me, I trust, to express views based on actual knowledge of conditions—views which are not founded on the superficial observation of a casual visitor.

To plunge *in medias res*, let me advise every one first of all to learn the language. All German medical men of culture—and they are all cultured—speak and understand English and French, and with invariable courtesy they will on many occasions seek to explain matters to the foreigner in his own language. Nevertheless, they can not be expected to do this all the time, and much of value will be lost to the American visitor unless he has at least a superficial knowledge of German medical terms. Moreover, he can not get about among the natives with any satisfaction nor appreciate the real sociologic conditions unless he can talk the language to some extent.

Before sailing get a Berlitz teacher and start talking. Get Ahn's little book, too, and Waller's "German-English Medical Dictionary." It is astonishing how much can be learned in two months by studying systematically one or two hours a day. Believe me, it is well worth the while. The Latin terms for anatomic conditions and to describe diagnosis and treatment are used more frequently than by us, and the Germans are accustomed to hear foreigners speak the language imperfectly. They catch the meaning if there is half a chance.

On arrival go first of all to a hotel—on the European plan necessarily, for there is no American plan, except in *pensions*, as the boarding houses are called. Then call at Langenbeck Haus, which is the meeting place of different medical societies and the general medical headquarters, very much like the Academy of Medicine of New York. See there the superintendent, Mr. Menzer, or his wife, who will give you the catalogue of the vacation courses, and observe the notices of matters of medical interest posted on the bulletin board. Buy a catalogue of the university lectures at any book store and also a little book entitled *"Das Medizinische Berlin."* By looking over these pamphlets you will learn much regarding the different hospitals and dispensaries—called here respectively *Klinik* and *Poliklinik*—as well as regarding laboratories, lectures and demonstrations. You see at once what is offered and you are prepared to make a choice.

Now about 1 o'clock go to the Terminus restaurant for dinner. This is the meeting place of Americans, whom you will easily recognize, for they have one or two tables reserved. Supplement the knowledge already gained by the pamphlets I have mentioned by getting practical pointers from your compatriots. If you are to stay a few weeks or longer it is cheaper and more convenient to rent a room near the hospital or other institution where you intend to spend most of your time. A suitable room with the usual breakfast of coffee and rolls supplied by the landlady can be rented for two or three marks a day. A mark is a little less than a quarter, so the expense is not great. By arranging by the week or month a cheaper rate may be secured, but beware that you give due notice of your intention to vacate—the fifteenth of the month if you are to leave the first—or you will be called on to pay for an extra month. You can get board and room in a pension at from four to five marks a day. The coffee and rolls are served in your room, as a rule, and dinner is called at 2 o'clock and supper at 8 o'clock. Most Americans find it more convenient to patronize the restaurant of which the name is legion.

It is important to conform to certain customs of the country at once or you may be considered no gentleman. Even if the great influx of Americans makes a deviation from established usage less conspicuous than was formerly the case, it is preferable to show a knowledge of social etiquette and a disposition to do as others do. Indeed, such a practice distinguishes the cosmopolitan traveler and is accepted as a mark of good breeding. You must learn the very first day how to bow. Bring the heels together as if to give a military salute and incline the whole body at an angle of 45 degrees, letting the head drop forward. Do this right and don't think nodding is sufficient. You are expected to take off your hat to those who salute you. When acknowledging the salutation of porters, tradesmen or attachés of hotels or hospitals it is enough to do as we do at home when we salute a lady. But in Berlin if you meet a lady you will not wait for her to recognize you but as soon as she is sighted you raise your hat and, holding it at almost arm's length above your head until she meets you, you make a half circle with your arm while you utter the proper salutation appropriate to the time of day. In this manner you exchange greetings with your professional colleagues and social equals. You will not shake hands when introduced except when the German, who may know of our American custom, offers to do so.

In entering a restaurant you take off your hat and hold it in your hand until you find a table that suits you. You have the pick except when you see a placard with the word *"Bestellt,"* meaning reserved, or *"Stammtisch,"* or *"Für Stammgäste,"* meaning for habitual customers. There is no head waiter as at home to order you to a certain table. If there is a crowd present and you find a vacant place at a table where others are sitting, take hold of the back of the chair, gaze at the seated guests, make the bow as above indicated and ask permission to join the little company by inquiring *"Gestatten Sie?"* The men will half rise from their seats to bow to you and will indicate their permission by the words *"Bitte schoen"* or *"Bitte sehr,"* while the ladies will incline their heads and smile pleasantly at you. When you have finished and have paid the waiter, seize the back of your chair again as in Act 1, bow to the guests and say the mystic word *"Mahlzeit."* The guests will give the countersign by repeating the word or

by saying *"Adieu"* or *"N'Abend"* as they return your salutation.

These expressions must be memorized and also the word *"Morgen,"* which is the equivalent of "good morning," and *"Tag,"* which means "good day." You use the word *"Morgen"* in salutation until about 1 o'clock, then the word *"Mahlzeit,"* which is the contraction of an invocation for a blessing on the meal, until afternoon. In bidding good-bye you say *"Adieu"* or *"Tag,"* and in the evening you say *"N'Abend."* When you enter and leave a shop you say the proper word and uncover while you are making your purchases. An exception is often made when a silk hat is worn. Much respect is apparently paid this article of headgear, which is called a *"Cylinder."* It is often kept on the head in the cafés and stores; in theaters, where it is obligatory to check umbrellas, overcoats and even ladies' wraps and hats, the silk hat is not relinquished, but held conspicuously in the hand or sometimes worn on the head if, for instance, the gentleman has the back seat in a box.

When you are invited to dinner do not fail to accept. You will have an abundance of good things to eat, drink and smoke, and you will find the hospitality most delightful. When your host begs you not to wear a *"Frack,"* as the dress suit is called, wear a Prince Albert, but when he states that evening clothes are not necessary and you know ladies are to be present, it will not be out of place and you will probably feel better if you put on your dress suit as you would do at home on such an occasion. The formal dinner hour is usually 8 o'clock. On arrival you shake hands with the host and hostess and bow low. If guests are assembled they will stand and form a circle around you while you are being introduced. Your name, with your titles, is mentioned and you make your bow. The guests are then named in turn and you bow as they do on each introduction. You then take your place in the circle to be introduced to the next arrival. When all are assembled a servant will hand you a card bearing the name of the lady whom you are to take in to dinner, and if you are a stranger the host will point her out to you. If you are the guest of honor, as was my privilege on several occasions, the hostess will take your arm as the doors to the dining room are thrown open and other couples will join in the march. Otherwise when the hostess gives the signal you salute the lady to whom your card assigns you and proceed to the dining-room with her on your arm.

It is difficult to describe a Berlin dinner party. There is a ceremonious formality and yet a freedom from stiffness and affectation which is most charming. The minute the hostess raises her glass to drink to the health of the guests, the stranger feels that he is among friends, and he at once enters heartily into the spirit of companionable conviviality that prevails. Different persons, in the course of the dinner, may drink to you. They will raise their glass and calling you by name will courteously ask permission. It is advisable for you, before dinner is over, to remember who has honored you and if possible, without any undue effort, to return the compliment. In any event, do not fail to specially drink to your hostess. A gentleman at the other end of the table may send greeting by the waiter. In that event, half rise from your seat to salute him as he drinks to you. When, in the course of two or three hours, the dinner is over, the guests all rise as the hostess gives the signal, they form in line, each lady taking the arm of her escort, and march back to the drawing-room.

Now ensues a pretty German custom which I first learned when I was a student in the little university town of Marburg thirty years ago. The guests salute the hostess and then one and another by shaking hands all around and saying *"Mahlzeit."* They bow low as they salute the ladies, and often kiss their hands. The gentlemen then light their cigars and many of the ladies smoke a cigarette. When leaving, the host and hostess are taken leave of in the drawing-room, and the servant who helps you on with your coat in the ante-room will expect a mark or two from each guest. The dinner call should be made within ten days and at 1 o'clock. The proper costume is the Prince Albert suit and silk hat. Overcoats are left in the ante-room when calling; even ladies are expected to remove their hats and wraps before being announced. The sofa, which is to be found in every drawing-room, is the seat of honor. You will sit on a chair unless it is insisted, as is usually the case, that you change to the sofa. In that event do as requested without undue parley.

(To be continued.)

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

"HEURISTIC."

BUFFALO, N. Y., Sept. 12, 1903.

To the Editor:—In the article on "Infectious Diseases," by Hektoen, in THE JOURNAL, August 15, p. 406, in the twenty-first line from the top of the left column appears the word "heuristic." Is it a misprint? If not, what is the meaning? I have examined many dictionaries and fail to find it. MEDICUS.

ANSWER.—The word is defined in the later and larger dictionaries, Webster's International, the Standard and the Century. In Webster the meaning is given as "serving to discover or find out," in the Standard as "aiding or guiding discovery, inciting to find out or invent," and in the Century Dictionary as "serving to find out or discover." Etymologically the word comes from the Greek εὑρισκειν, to find out. The word has been mostly used in pedagogic literature. In Baldwin's "Dictionary of Philosophy and Psychology" the "heuristic method" is given as one "that stimulates to invention or discovery." The word has not yet come into general use, but it is an excellent one for its purpose, and as it has no single substitute will, we believe, soon come to be more familiar.

Marriages.

GEORGE H. WARDNER, M.D., La Porte, Ind., September 10.

DANIEL R. BROWER, JR., M.D., Chicago, to Miss Olive Pope Magill of Wichita, Kan., September 15.

GEORGE E. REYNOLDS, M.D., Haywards, Cal., to Miss Lydia Platt of Oakland, Cal., September 7.

WM. H. HURLEY, M.D., Northfield, Vt., to Miss Nettie V. Hoffacker, at Baltimore, September 10.

WILLIAM A. COOLING, M.D., Wilton, Iowa, to Miss Ione Parker of Texas, at Muscatine, Iowa, September 11.

H. A. HAYNES, M.D., Ionia, Mich., to Miss Inez E. Harvey of St. Albans, Vt., September 9.

Deaths.

Jesse C. Pfaff, M.D. Medico-Chirurgical College, Philadelphia, 1902, chief of the orthopedic department at the Medico-Chirurgical Hospital, died at St. Joseph's Hospital, Philadelphia, September 6, from typhoid fever, after an illness of ten days, aged 22. The Lehigh County Medical Society, at a meeting, September 8, passed resolutions regarding the death of Dr. Pfaff, and appointed a committee to attend his funeral.

John W. Waughop, M.D. Long Island College Hospital, Brooklyn, 1865, formerly superintendent of the Western Washington Hospital for the Insane, Fort Stellacoom, but for seven years a resident of Keala, Kauia, Hawaii, died at sea, August 31, while *en route* from Hawaii to San Francisco, aged 64.

Norton Folsom, M.D. Harvard University Medical School, Boston, 1864, chief medical inspector of an army corps during the Civil War, and at one time superintendent of the Massachusetts General Hospital, died at his home in Cambridge, Mass., September 12, aged 61.

H. F. Frederick, M.D. Atlanta (Ga.) Medical College, 1894, despondent on account of cancer of the stomach, from which he had suffered for several months, committed suicide by shooting himself through the head, at his home in Hawkinsville, Ga., September 10.

Peter S. Greenamyer, M.D. Jefferson Medical College, Philadelphia, 1872, a member of the American Medical Association, for many years surgeon for the Pennsylvania Lines at Orrville, Ohio, died at his home in that place, September 11, after a prolonged illness, aged 67.

Samuel Richardson, M.D. Toronto University Medical Faculty, 1875, of Detroit, Mich., died at St. Mary's Hospital in

that city, September 3, two weeks after an operation for disease of the stomach, from which he had suffered for several months, aged 58.

Alexander Bruce McMurray, M.D. Western Reserve University, Cleveland, 1871, a member of the American Medical Association and the Ohio State Medical Society, died at his home in Marion, Ohio, after a prolonged illness, September 8, aged 66.

Charles A. Murray, M.D. Geneva (N. Y.) Medical College, 1853, for half a century a practitioner of Vanetten, N. Y., died at his home in that place, September 3, from heart disease, after a short illness, aged 77.

Stephen P. Yeoman, M.D. Rush Medical College, Chicago, 1854, died at the Soldiers' Home Hospital, Marshalltown, Iowa, September 8, several weeks after a fracture of the right hip, aged 81.

Johnson A. White, M.D. Ohio Medical College, Cincinnati, died at his home in Liberty Township, Jackson County, Ohio, September 3, six weeks after an operation for appendicitis, aged 60.

Theodore R. McDonald, M.D. Detroit College of Medicine, 1890, of Detroit, died at Hayden Hospital in that city, September 14, five days after an operation for gallstone disease, aged 41.

Joseph P. Oliver, M.D. Harvard University Medical School, Boston, 1871, of Boston, lecturer on diseases of children at the Harvard Medical School, died in Paris, September 11, aged 58.

John T. Donaldson, M.D. Medical College of the State of South Carolina, Charleston, 1867, died at his home in Eastaboga, Ala., September 3, after an illness of several years.

James C. Harrison, M.D. Barnes Medical College, St. Louis, 1899, died at his home in Webber's Falls, Cherokee Nation, I. T., from malarial fever, September 6, aged 35.

George W. Stevenson, M.D. Tulane University, New Orleans, 1903, died at his father's home in Nicholson, Miss., September 8, after an illness of four months, aged 26.

Robert W. B. Cornelius, M.D. Hahnemann Medical College, Philadelphia, 1874, died suddenly from heart disease at his home in Philadelphia, August 30, aged 50.

Amos E. Heilman, M.D. College of Physicians and Surgeons, Baltimore, 1884, died at his home in Rural Valley, Pa., September 10, from typhoid fever, aged 47.

Isaac J. Newton, M.D. Tulane University, New Orleans, 1858, a retired physician of Hamburg, Ark., died at his home in that place, September 7, aged about 80.

James W. McLaughlin, M.D. University of Toronto, 1864, and gold medallist of his class, registrar for West Durham, Ont., died, August 10, aged 62.

Elias Miller, M.D. College of Physicians and Surgeons, Chicago, 1886, died at his home in Kensington, Ill., September 5, after a lingering illness, aged 65.

William Edward Conroy, M.D. College of Physicians and Surgeons, New York, 1880, died recently at Saginaw, Mich., and was buried September 2.

Frederick J. Locke, M.D. Eclectic Medical Institute, Cincinnati, 1864, died at his home in Newport, Ky., September 11, after a short illness, aged 74.

Albert Dickerson, M.D. Louisville Medical College, 1889, of New Athens, Ohio, dropped dead while making a call near that place, September 7, aged 45.

Elijah J. Puckett, M.D. Medical College of Indiana, Indianapolis, 1881, died at his home in Muncie, Ind., September 10, after a lingering illness.

William H. Poole, M.D. Medical College of Georgia, Augusta, 1868, died at his home in Douglasville, Ga., September 2, from neuralgia of the heart.

Jacob K. Metz, M.D. Jefferson Medical College, Philadelphia, 1852, died at his home in Allensville, Pa., September 11, after a long illness, aged 78.

James W. Hill, M.D. Kentucky School of Medicine, Louisville, 1861, died at his home in Bardstown, Ky., September 1, after a long illness, aged 75.

Lucius S. Ollie, M.D. University of Toronto, 1859, and gold medallist of his class, died at his home in St. Catherines, Ont., August 15, aged 73.

Sidney A. Campbell, M.D. Jefferson Medical College, Philadelphia, 1849, died at his home in West Pittston, Pa., September 12, aged 83.

J. Paul Jones, M.D. New Orleans School of Medicine, 1861, died suddenly from heart disease at his home in Camden, Ala., September 13.

Frank M. Stringfield, M.D. University of Georgetown, D.C., 1881, died suddenly in his apartments in Chicago, September 12, aged 62.

James M. Forbes, M.D. Chicago Homeopathic Medical College, 1889, was murdered in a drug store in Chicago, May 13, aged 44.

David Beeler, M.D. University of Louisville, 1883, died at his home in Powers, Ky., from neuralgia of the heart, September 7, aged 75.

Philip Woolf, M.D. Bellevue Hospital Medical College, New York, 1868, died at his home in New York City, August 31, aged 58.

Joseph M. Donald, M.D. Tulane University, New Orleans, 1854, died at his home in Harrell, Ala., September 4, aged 70.

B. R. Donelson, M.D. New Orleans School of Medicine, 1861, died at Pine Bluff, Ark., recently, from cancer of the liver.

Samuel L. Herring, M.D. College of Physicians and Surgeons, Baltimore, 1881, died recently at his home in Clovis, Cal.

Hiram Hayward, M.D., died suddenly at his home in Worth Township, Sanilac County, Mich., September 1, aged 87.

John H. Dye, M.D. Eclectic Medical College of the City of New York, 1873, of Tonawanda, N. Y., died recently.

C. E. Warren, M.D., died suddenly from heart disease at his home in Roundbottom, Ohio, September 3, aged 29.

James H. Sanford, M.D., of Shelbyville, Ind., committed suicide, September 7, while despondent, aged 65.

John Q. A. Vale, M.D., of Homer, Minn., died in Winona, Minn., September 3, after a long illness, aged 77.

Stuart McArton, M.D. Trinity Medical College, Toronto, 1876, of Paisley, Ont., died August 3, aged 51.

William E. Stewart, M.D. Louisville Medical College, 1875, died at his home in Clanton, Ala., August 31.

DeWitt H. Martyn, M.D. University of Toronto, 1866, Kincardine, Ont., died July 19, aged 66.

John F. Richards, M.D., of Tomah, Wis., died September 3, in Milwaukee, aged 87.

Book Notices.

THE PRINCIPLES OF OBSTETRICS. A Practical Manual for the Student and General Practitioner. By Stanley Perkins Warren, M.D., Portland, Me., Obstetric Surgeon to the Maine General Hospital. Superbly Illustrated by 165 Line and Half-tone Engravings. Cloth. Pp. 385. Price, $3.00 net. New York: William Wood & Co.

This book will be appreciated by students who wish a compact and convenient treatise on obstetrics. It is well illustrated.

ILLINOIS STATE BOARD OF HEALTH. Report on Medical Education and Official Register of Legally Qualified Physicians. 1903. Embracing Medical Practice in Illinois, Medical Colleges in Illinois and Faculties, Medical Societies in Illinois and Officers, Pension Examining Boards in Illinois, Requirements for Practice in the United States, Medical Colleges in the United States, and an Official Register of Physicians. Springfield: Illinois State Register. 1903.

The Illinois State Board of Health republishes this year its Report on Medical Education and Official Registration of Legally Qualified Physicians. It includes a number of valuable facts in regard to medical colleges and societies in Illinois and brief statements of the requirements for practice in the various states and territories brought up to the spring of the present year. There have been some changes since then, as noted in THE JOURNAL, but in most cases the laws are unchanged. The opinions obtained from the attorney-general in regard to the medical practice laws and other subjects are a valuable feature of the report.

A COURSE OF LECTURES ON MEDICINE TO NURSES. By Herbert E. Cuff, M.D., F.R.C.S., Medical Superintendent Northeastern Fever Hospital, Tottenham, London. Fourth Edition. Cloth. Pp. 270. Price, $1.25 net. Philadelphia: P. Blakiston's Son & Co. 1903.

Nurses stand in a peculiar relation between the laity and the profession, and the question sometimes arises how far a little knowledge is a dangerous thing. Some nurses, as the one quoted in a recent communication to the *British Medical Journal*, evidently have suffered from a certain amount of

knowledge of disease, not enough in amount, however, to be useful to them. This book may be said to be a small compendium of practice, exceedingly brief and hardly sufficient to guide even a nurse in actual practice, though one that will perhaps meet the natural desire of anyone who is anxious to know something about the various diseases. We notice some little inaccuracies, for example the definition of germs as being invariably of vegetable nature, all belonging to the order of fungi. The book is one that will do no harm in the hands of any intelligent, well-meaning nurse.

Miscellany.

Clippings From Lay Exchanges.

WOUND LOCALIZATION.

"Sheriff Reed has captured Eugene Ledford, the young man who shot Felmet in the West End, two months ago. . . . ."—*Asheville* (N. C.) *Daily Citizen*, Aug. 21, 1903.

WHAT TOADSTOOLS CONTAIN.

"Three families were poisoned last evening by eating toadstools. . . . . Dr. —— says the symptoms indicate that the toadstools contained ptomaine poisoning."—*Chicago Examiner*, Aug. 24, 1903.

WHERE DID HE GET IT?

"Dr. —— has completed his investigations into the death of ——, aged three weeks, and found that death was due to an artificial foot."—*New Haven* (Conn.) *Palladium*, Aug. 15, 1903.

PILES OR PYELITIS?

"Joseph Fuma, the five-months-old son of ——, is at the hospital at . . . . The infant was suffering from an intestinal obstruction called 'pyelitis.' . . . . The obstruction was removed . . . ."—*Richmond* (Va.) *Leader*, Aug. 12, 1903.

SOOTHED BY COMMUNION AND CHLORAL.

"Life . . . . Prolonged by Means of Stimulants and Concentrated Nourishment— . . . .—Soothed Last Evening by Religious Service of Last Communion and a Dose of Chloral— . . . ."—*Johnstown* (Pa.) *Democrat*, July 6, 1903.

NO ANTISEPTIC WAS GIVEN.

"Yesterday . . . . Herbert —— was kicked and painfully hurt by a mule colt. . . . . A physician was summoned . . . . and dressed the wound. . . . . The boy stood the operation very well, considering the fact that no antiseptic was given."—*Durham* (N. C.) *Morning Herald*, Aug. 16, 1903.

IRRITANT ANTIDOTE.

"Joseph B. —— had a most exciting experience . . . . with a copperhead (which bit his finger). On the afflicted hand were several large black spots showing that the poison deposited in the blood was virulent. However, he went home feeling pretty good after the physician had administered a poison irritant."—*Daily Democrat*, Johnstown, Pa., July 7, 1903.

HIS EYE WAS HIS ONLY TOUGH SPOT.

"William —— lost his left eye by the explosion of a dynamite bomb . . . . it is thought the fragment that destroyed his eye would have caused death had it hit him anywhere else."—*De Ruyter* (N. Y.) *Gleaner*, July 9, 1903.—"The opinion of the physicians is that if the fragments of the bomb had struck him in any other place than they did he would probably have been instantly killed."—*Syracuse* (N. Y.) *Herald*, July 6, 1903.

Dentistry in Medical Colleges.—The National Dental Association at the recent meeting held at Asheville, N. C., adopted the following resolution: *"Resolved*, That it is the sense of the National Dental Association that each Medical College in the United States should include in its curriculum a lectureship on oral hygiene, prophylaxis and dental pathology." The committee representing the National Dental Association feels that with the introduction of the teaching of oral hygiene in the public schools, and with the co-operation of medical men who have been specially instructed on this subject, a great stride will have been made toward the prevention of caries of the teeth, not to mention many other good results to the general system, which would surely follow a better care of the oral cavity.

State Boards of Registration.

Next New Jersey Examination.—The regular examination of the State Board of Medical Examiners of New Jersey will be held at Trenton, N. J., on Tuesday, Tuesday evening and Wednesday, October 20-21. Application for admission to this examination should be made before October 10. Applicants must possess a high school diploma issued after four years of study, or its equivalent as determined by the state superintendent of public instruction, and must have had four courses of medical lectures of seven months each in different years.

Oklahoma Report.—Dr. E. E. Cowdrick, Enid, secretary of the Oklahoma Territorial Medical Examining Board, reports that a written examination of 18 applicants was held at Enid, September 17, and 9 passed and 9 failed. The questions asked numbered 72 on 9 subjects and no average was definitely marked against each candidate, the requirement being simply that his answers be 66 2/3 per cent. correct on each subject. Those who passed were graduates from the following colleges, one from each unless otherwise specified: Creighton Med. Coll. (1902); Univ. Med. Coll., Kansas City (1900); Marion-Sims Med. Coll., St. Louis (1903); Maryland Med. Coll. (1903); Western Univ., London, Ont. (1900); Washington Univ., St. Louis (1897); Memphis Hosp. Med. Coll. (1903); and two from Louisville Med. Coll. (both 1903). Those who failed were from: Univ. of Texas, Galveston (1902); Missouri Med. Coll., St. Louis (1894); Kentucky School of Med. (1887); Maryland Med. Coll. (1903); two from Barnes Med. Coll. (1897 and 1892); two from Keokuk Med. Coll. (1881 and 1901), and another was not a graduate, but had had twelve years of practice.

Texas Report.—Dr. M. M. Smith, secretary of the Board of Medical Examiners for the state of Texas, reports that at the examination held at Austin, June 15 to 18, 1903, 24 candidates were examined, of whom 16 passed and 8 failed. Of those who passed, 8 were graduates; of those who failed, 2. Applicants are not required to be graduates of medical schools, but must have attended at least two sessions at a medical college. In the summary below a star indicates an undergraduate. A percentage of 75 is required on a written examination. The number of subjects in this examination was 13, questions, 125.

PASSED.

Candidate.	Schl. of Pract.	College.	Year Grad.	Per Cent.
1	R.	Ft. Worth Univ. and Univ. of Nashville.	*	78
12	R.	Fort Worth University	*	79
2	R.	Kansas Medical College	1903	75

The questions asked follow:

SURGERY.

1. Give the indications for the ligation of the common carotid artery, and describe the operative procedure. 2. Differentiate a stone in the bladder, in the ureter, and in the kidney. 3. Give the differential diagnosis between dislocation of the hip joint and fracture of the surgical neck of the femur. 4. Name the chief varieties of cancer. 5. In case of threatened death from general anesthesia what methods of resuscitation would you adopt? 6. Describe the

method of passing a hard (steel) catheter on the male. 7. What are the symptoms of dislocation of the lower jaw; and how would you effect its reduction? 8. Describe the symptoms and treatment of fracture of the ribs. 9. Describe the varieties of clubfoot. 10. How would you differentiate between embolus and hemorrhage (intercranial) of one of the branches of the middle meningeal artery? Give treatment and prognosis.

EYE, EAR, NOSE AND THROAT.

1. Give the symptoms of mastoid involvement of otitis media. 2. Give the most frequent causes of otitis media, chronic and acute. 3. Give the symptoms and treatment of adenoids in the pharynx. 4. What is glaucoma? Give its causes, symptoms and treatment of both chronic and acute. 5. How would you recognize and treat polypi?

CHEMISTRY.

1. Into what grand divisions is the subject of chemistry divided? 2. Explain and illustrate the principle of empirical and rational formulæ. 3. What is meant by percentage composition? 4. Explain and illustrate the term isomerism. 5. What is bismuth, and what are the properties of bismuth? 6. On what does Reinsch's test for arsenic depend? 7. Describe the element mercury and name its compounds used in medicine. 8. What are the differences in the tests of arsenic and antimony? 9. What is ozone? 10. Describe carbon dioxid, and name some of the ways by which it may be produced.

PRACTICE OF MEDICINE.

1. Diagnosis and treatment: Of angina pectoris. 2. Of cerebral apoplexy. 3. Of appendicitis. 4. Of asthma. 5. Differential diagnosis of suppurative pleuritis and abscess of liver. 6. Causes and treatment: Of Cholera infantum. 7. Of infantile convulsions. 8. Differential diagnosis of spasmodic croup and diphtheria. 9. Diagnosis and treatment: Of delirium tremens. 10. Of lymphadenoma (or Hodgkin's disease).

OBSTETRICS.

1. Asepsis and antisepsis, how applied in midwifery: (a) As regards the accoucher. (b) As regards the parturient. (c) As regards the child. 2. How should the placenta be delivered at term? What is the management of retained placenta? 3. To what form of morbus Brightii are pregnant women most liable? How would you diagnose and treat it? And how measure the severity? 4. What is placenta previa? Name its causes, varieties, symptoms and management. 5. Describe the symptoms and management of an incomplete abortion. 6. Describe the position of patient and physician for the readiest and safest means of applying the forceps. 7. Diagnose and state how to conduct a head-last labor. 8. Give cause, symptoms and treatment of asphyxia of the new born. 9. Give the prevention, symptoms, treatment and prognosis of ophthalmia neonatorum. 10. What is meant by prolapse of the funis? When does it occur? What are the dangers? How would you manage such a case?

MATERIA MEDICA.

1. What are the physiologic actions: Of iodin? 2. Of salicylic acid? 3. What are the preparations, doses and physiologic actions of ergot? 4. What are the tests for morphin, and give antidote. 5. How would you treat a case of veratrum poisoning and what are the uses of veratrum viride: 6. Give the physiologic action: Of jaborandi. 7. Of opium and antidote. 8. Of cocain. 9. How would you treat a case of copper poisoning? 10. How would you treat a case of poisoning by iodin.

PATHOLOGY.

1. Describe the minute pathology of a liver which has undergone fatty degeneration. 2. How does chronic interstitial differ from chronic parenchymatous nephritis; describe the pathology of each. 3. Describe the pathological condition known as erosion of the cervix. 4. Give pathology of the various stages of acute lobar pneumonia. 5. Give a theory of inflammation, and what are the sequelæ of inflammation? 6. (a) What constitutes malignancy of tumors? (b) Name and give principal locations of malignant tumors. (c) Give causes of tumor cachexia. 7. Give the various theories of causation of fever. 8. Give the pathology of the different inflammations of the spleen. 9. Describe the pathology of a third degree burn of the skin produced by hot metal. 10. What are the forms of pathologic pigmentation?

ANATOMY.

1. Name the bones of the face. 2. Name the ligaments and give the peculiarities of the shoulder joint. 3. What muscles are attached to the crest of the pubes? 4. Give the landmarks for the palmar arches. 5. What veins form the portal system? 6. The axillary glands receive the lymphatic vessels from what part of the body? 7. Give the course and landmark of the duct of the parotid gland. 8. Give the relations of the thyroid gland. 9. Give boundaries and contents of the popliteal space. 10. What nerves supply the diaphragm?

HISTOLOGY.

1. Trace a drop of fluid from a Bowman's capsule to the pelvis of the kidney, naming and giving the structure of the different parts of the uriniferous tubules through which it would pass. 2. (a) Give the shape, size and structure of a human red blood cell. (b) The structure and relative number of the various forms of the white blood cells. (c) Could you tell whether the red blood cells of a given clot were mammillian or not? If mammillian, human or not? Give reasons for your answer. 3. Give the course of the portal blood through the liver, also the course of the bile from the time of its secretion by the liver cells until it reaches the gall bladder, giving the structure of the ducts through which it would have to pass. 4. Describe the structure of the trachea, a medium-sized bronchus, an alveolar duct and an alveolus of the lung. 5. Give a description of lymphatic vessels, lymph cavities and lymph glands, and give examples of each and where each may be found. 6. (a) Describe the structure of involuntary muscle and give three examples of where found. (b) Give structure of heart muscle and the ending of the nerve fibers supplying same. 7. Describe a nucleus, a nucleolus and protoplasm. 8. (a) Give histology of a medium-sized artery. (b) Give histology of a vein. 9. Explain the difference between mucous and serous membranes. 10. (a) Describe a nerve trunk. (b) Describe a non-medullated nerve fiber. (c) Describe a medullated nerve fiber. (d) The two types of nerve cells in the brain and cord. (e) The structure of gangila.

PHYSIOLOGY.

1. What is urea, give the daily quantity excreted, and mention the influences which govern this quantity? 2. Give the quantity of food required per day by a healthy person. 3. The secretions of what glands form the saliva? 4. Give the physiologic action of the saliva. 5. Give the physiologic action of bile. 6. How is the digested food absorbed and through what channels does it reach the circulation? 7. What are the functions of the red blood corpuscles? 8. Give the composition of atmospheric air; what changes occur in it during respiration? 9. How is animal heat produced? 10. What forces cause the blood to flow through the veins?

GYNECOLOGY.

1. Describe a curettement. What are the dangers? 2. Give the indications for and the technic of ventrofixation. 3. Differentiate between retroflexion and retroversion of the uterus. 4. Vaginal douche. What are the indications for and how given? 5. When is an Alexander operation indicated? Give technic of operation. 6. How is a vaginal hysterectomy done? 7. Given a complete laceration of the perineum, how should it be repaired? Name the two most important muscles to be restored. 8. How would you prepare "normal salt solution?" How and when use it by infusion? How and when use it by hypodermoclysis? How and when use it by enterociysis? 9. How would you prepare a patient for a laparotomy? 10. What is the proper way of making a gynecologic examination?

MEDICAL JURISPRUDENCE.

1. Define a poison. 2. Give definitions of an irritant, and one of neurotic poison, and give example of each. 3. Define ordinary and expert witness. 4. What is infanticide? 5. What is paranoia? 6. Define civil malpractice. 7. Define criminal malpractice. 8. What is meant by civil and criminal responsibility? 9. Define the following terms, viz.: (a) Kleptomania. (b) Pyromania. (c) Dipsomania. 10. What are the evidences of death from lightning?

THERAPEUTICS.

1. Give the dose, indications for use, frequency of administration and method of giving diphtheria antitoxin. 2. Enumerate the commonly used bromids, their doses and mention briefly their therapeutic use. 3. Give in detail the use of chloroform as an anesthetic, the preparation of the patient, method of administration, the danger signals and manner of treating same when present. 4. Give the dose and therapeutic use of creosote and its common derivatives. 5. Give the various therapeutic uses of calomel, and the dose employed in each. 6. Give in detail the dose, use and contraindications of iodid of potassium. 7. Describe in detail the general treatment applicable to poisoning from any drug. 8. Give the dose and therapeutic use of veratrum viride. 9. Give the dose and indications for use of quinin and arsenic in the treatment of malaria. 10. Give briefly the treatment of strychnin and opium poisoning.

HYGIENE.

1. What hygienic and sanitary measures should the attending physician take to prevent the spread of typhoid fever? 2. Construct a model school room for the accommodation of 40 pupils. 3. What are some of the evidences of contaminated drinking water, and give the method of purifying the same. 4. Give the origin and prevention of malaria. 5. Give a good method of sewage disposal (municipal). 6. Name the dangerous impurities of the air in crowded, unventilated rooms. 7. What do you understand by preventive medicine? 8. Do you know of any preventive of tuberculosis? 9. Name the communicable diseases of school children. 10. Give the hygiene of the new-born babe.

Medical Organization.

Organization in Texas.

Dr. T. J. Bennett, councilor for the Seventh District, reports that he has organized the following county societies: Williamson, Travis, Caldwell and Lee. Dr. W. B. Russ, councilor for the Fifth District, reports having organized societies in the following counties: Bexar, Guadalupe, Medina, Val Verde, Comal and Maverick.

BROWN COUNTY (TEXAS) MEDICAL SOCIETY.

Physicians of Brown County met at Brownwood the last week in August and organized a county medical society with ten charter members.

MEDINA COUNTY (TEXAS) MEDICAL SOCIETY.

Dr. Witten B. Russ, San Antonio, councilor for the Fifth (western) District, has organized this society with seven members and the following officers: Dr. J. R. Evans, Devine, president; Dr. John F. Beckmeyer, Hondo, vice-president; Dr. John T. Fitzsimon, Castroville, secretary-treasurer, and Drs. J. R. Evans, W. E. Patterson, Medina, and John F. Beckmeyer, censors.

VAL VERDE COUNTY (TEXAS) MEDICAL SOCIETY.

Dr. Witten B. Russ, San Antonio, councilor for the Fifth (western) District, has organized this society with six members and the following officers: Dr. John K. Moeur, Del Rio, president; Dr. Horace B. Ross, Del Rio, vice-president; Dr. S. L. Boren, secretary-treasurer, and Drs. Horace B. Ross, D. T. Atkinson and Oscar C. West, censors.

MAVERICK COUNTY (TEXAS) MEDICAL SOCIETY.

Dr. Witten B. Russ, San Antonio, councilor for the Fifth (western) District, has organized this society with six members and the following officers: Dr. R. N. Lane, Eagle Pass, president; Dr. A. H. Evans, vice-president; Dr. Malone Duggan, Eagle Pass, secretary-treasurer, and Drs. Evans, L. Hume and Duggan, all of Eagle Pass, censors.

GUADALUPE COUNTY (TEXAS) MEDICAL SOCIETY.

Dr. Witten B. Russ, San Antonio, councilor for the Fifth (western) District, has organized this society with an initial membership of 11, and the following officers: President, Dr. Marvin B. Grace, Seguin; vice-president, Dr. F. R. Williams, Kingsbury; secretary-treasurer, Dr. D. A. Watson, and censors, Drs. F. R. Williams, Kingsbury, William Myers, Seguin, and Asa M. Stamps, Seguin.

COMAL COUNTY (TEXAS) MEDICAL SOCIETY.

Dr. Witten B. Russ, San Antonio, councilor for the Fifth (western) District, announces the organization of this society with four members and the following officers: Dr. Henry Leonard, New Braunfels, president; Dr. L. V. Weathers, vice-president; Dr. Alfred H. Noster, New Braunfels, secretary-treasurer, and Drs. Alonzo Garwood, Alfred H. Noster and Henry Leonard, all of New Braunfels, censors.

NUECES COUNTY (TEXAS) MEDICAL ASSOCIATION.

Dr. Arthur E. Spohn, Corpus Christi, councilor for the Sixth (Corpus Christi) District, on September 5, organized this association with the following officers: Dr. Arthur E. Spohn, Corpus Christi, president; Dr. Alfred G. Heaney, Corpus Christi, vice-president; Dr. Henry Redmond, Corpus Christi, secretary; Dr. J. D. Hooker, Alice, treasurer, and Drs. Henry S. Burke, Corpus Christi, W. T. Harris, Mathis, and Walter F. McMullen, Rockport, censors.

BURLESON COUNTY (TEXAS) MEDICAL ASSOCIATION.

Dr. Sam R. Burroughs, Buffalo, councilor for the Eleventh (Brazos Valley) District, met the physicians of the county at Caldwell, September 3, and organized a county society with a charter membership of seven, and the following officers: Dr. James P. Oliver, president; Dr. Joseph W. Matthews, vice-president; Dr. B. O. McLean, secretary and treasurer, all of Caldwell, and Drs. Joseph W. Matthews, Caldwell, Robert E. B. Bledsoe, Somerville, and Duncan M. Broach, Merle, censors.

GRIMES COUNTY (TEXAS) MEDICAL ASSOCIATION.

The physicians of the county met at Anderson, September 5, and were addressed by Dr. Sam R. Burroughs, Buffalo, councilor for the Eleventh (Brazos Valley) District, on the benefits of county organization. A county medical association was then formed with an initial membership of 15, and the following officers: Dr. Fred B. Johnstone, Anderson, president; Dr. William Hayne, Anderson, vice-president; Dr. B. H. Bennett, secretary, and Drs. H. J. Palmer, Yarboro, A. J. Burke and A. J. Whitworth, censors.

Columbia County (Wis.) Medical Society.

This society was organized at Portage, September 9, with 14 members. Dr. James J. Howard, Columbus, was elected president; Dr. John R. Binnie, Poynette, vice-president, and Dr. Frederick D. Bentley, Portage, secretary and treasurer.

Fond du Lac County (Wis.) Medical Society.

Dr. Eugene L. Boothby, Hammond, councilor of the Eleventh District, met the physicians of the county, September 9, and organized a county medical society, of which Dr. Henry Hannum, Bayfield, was elected president, and Dr. H. G. Lampson, Washburn, vice-president.

Tippecanoe County (Ind.) Medical Society.

This society met at Lafayette, September 15, and with the aid of Dr. George F. Keiper, councilor for the Tenth District, reorganized and adopted a constitution and by-laws in conformity with those of the Indiana State Medical Society and the American Medical Association.

Muskingum County (Ohio) Medical Society.

At the annual meeting, September 8, the society adopted the constitution and by-laws recommended by the state and National organizations, and elected Dr. C. U. Hanna, president; Dr. Abdul M. Templeton, vice-president; Dr. William F. Sealover, secretary, and Dr. Charles P. Sellers, treasurer, all of Zanesville.

Forsyth County (N. C.) Medical Society.

This society was reorganized at a meeting held in Winston-Salem, September 8, with the following officers: Dr. H. S. Lott, Winston-Salem, president; Dr. Edward F. Strickland, Bethania, vice-president; Dr. Robert D. Jewett, Winston-Salem, secretary, and Drs. A. Y. Linville, Waughtown; Henry T. Bahnson, Winston-Salem, and David N. Dalton, Winston-Salem, censors.

Jefferson County (Ind.) Medical Society.

This society met in Madison, September 7, and by unanimous vote decided to reorganize in accordance with the recommendations of the American Medical Association. The following officers were re-elected: Dr. William A. McCoy, Madison, president; Dr. Nicholas A. Kremer, secretary-treasurer, and Drs. Charles R. Ryker, Manville, Jefferson Cooperider Madison, and Fred H. Austin, North Madison, censors.

Dade County (Fla.) Medical Society.

On September 3 thirteen physicians of Dade County met at Miami, organized a county medical society, adopted a constitution and by-laws conforming to those of the state society and the American Medical Association, and elected the following officers: Dr. R. H. Huddleston, Miami, president; Dr. N. O. Burnham, West Palm Beach, vice-president, and Dr. E. W. Pugh, Miami, secretary and treasurer.

Ringgold County (Iowa) Medical Society.

The members of this society met at Mount Ayr, August 13, and reorganized under the rules laid down by the state and National organizations. Dr. Benjamin B. Waring, Maloy, is president; Dr. John W. Greenman, Kellerton, vice-president; Dr. Samuel Bailey, Mount Ayr, secretary-treasurer, and Drs. William Horne, Mount Ayr, Cassius T. Lesan, Mount Ayr, and B. H. Miller, Redding, compose the board of censors.

Pearl River-Marion County (Miss.) Medical Society.

This society was recently organized by Dr. Hyman McM. Folkes, Biloxi, councilor for the Tenth District, at Lumberton, with the following officers: Dr. William J. Hunnicutt, Poplarville, president; Dr. Theodore B. Ford, Columbia, vice-president for Marion County; Dr. W. W. Hall, vice-president for Pearl River County; Dr. Charles C. Bass, Columbia, secretary; Dr. Robert W. Thompson, Lumberton, treasurer, and Drs. Stephen B. Harmon, Lumberton, Buford Larkin, Columbia, and L. L. Polk, Purvis, censors.

Benton County (Iowa) Medical Society.

Seventy-five per cent. of the physicians of Benton County met at Vinton, September 8, and organized a county medical society in affiliation with the state and National organizations. The following officers were elected: Dr. Marion Meredith, Vinton, president; Dr. Samuel H. Watson, Blairstown, vice-president; Dr. John E. Luckey, Vinton, secretary; Dr. Clark C. Griffin, Jr., Vinton, treasurer; Drs. Clark C. Griffin and Jay P. Whitney, Vinton, and Irvin S. Boles, Shellsburg, censors, and Dr. James McMorris, Belle Plaine, delegate to the state society.

Societies.

COMING MEETINGS.

American Academy of Railway Surgeons, Chicago, Oct. 1-2.
Colorado State Medical Society, Denver, Oct. 6-8.
Medical Association of the District of Columbia, Washington, Oct. 6.
Idaho State Medical Society, Boise, Oct. 8-9.
Mississippi Valley Medical Association, Memphis, Tenn., Oct. 7-9.
Vermont State Medical Society, Bellows Falls, Oct. 15-16.
New York State Medical Association, New York City, Oct. 19-22.

Hawaiian Territorial Medical Society, Honolulu, Nov. 7.
Oklahoma Territory Medical Association, Oklahoma City, Nov. 11.

Iowa State Association of Railway Surgeons.—The tenth annual meeting will be held at Des Moines, October 14 and 15.

American Academy of Railway Surgeons.—The tenth annual meeting will be held in the Great Northern Hotel, Chicago, October 1 and 2, under the presidency of Dr. Luther Sexton, New Orleans.

Canadian Medical Association.—Dr. Simon J. Tunstall, Vancouver, B. C., was elected president; Dr. George Elliott, Toronto, Ont., re-elected secretary and Dr. Henry B. Small, Ottawa, Ont., re-elected treasurer. The next meeting will be held in Vancouver.

Medical and Chirurgical Faculty of Maryland.—The semi-annual meeting will be held September 24 and 25 at Pen Mar on the Western Maryland Railway in the Blue Ridge Mountains. Matters of legislation will be discussed, including changes needed in the medical examination and licensing laws. The constitution and by laws will be so modified as to place the society in full accord with the American Medical Association and the county societies.

Medical Society of the Missouri Valley.—At the sixteenth annual meeting held in Omaha, September 14, the following officers were elected: President, Dr. A. D. Wilkinson, Lincoln, Neb.; vice-presidents, Drs. Robert R. Williams, Manning, Iowa, and J. Harvey Cleaver, Council Bluffs, Iowa; secretary, Dr. Charles Wood Fassett, St. Joseph, Mo., and treasurer, Dr. Donald Macrae, Council Bluffs, Iowa. The next meeting of the society will be held at Lincoln, Neb. An amendment to the constitution was adopted, making Council Bluffs the annual meeting place, the sessions to convene on the fourth Thursday of August of each year. The semi-annual meetings will be held as heretofore at places in the Missouri Valley.

Cumberland Valley Medical Society.—This society was organized at Mont Alto Park, September 8, with the following officers: President, Dr. Robert W. Ramsey, Chambersburg, Pa.; vice-presidents, Drs. James Evelyn Pilcher, U. S. Army, retired, Carlisle, T. H. Weagley, Marion, Pa., and James W. Humrichouse, Hagerstown, Md.; secretary, Dr. John J. Coffman, Scotland, Pa.; assistant secretary, Dr. P. Brough Montgomery, Chambersburg, Pa., and Americus R. Allen, Carlisle, Pa., and treasurer, Dr. John Montgomery, Chambersburg, Pa. Forty physicians from Cumberland Valley towns were present. Dr. Joseph T. Rothrock of the Pennsylvania Forestry Department, who is in charge of the Mont Alto Reservation and White Pine Consumption Sanitarium Camp, made an address on the open-air treatment of tuberculosis. Major James Evelyn Pilcher, U. S. A., offered a motion, which was adopted, that the state of Pennsylvania be urged to appropriate sufficient money for the full development of the sanitarium, which is now so crowded that scores of patients are turned away weekly.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Benzoin Preparations.

The preparations of benzoin have been employed, both locally and internally, with excellent results in the treatment of various conditions. H. R. Coston, in *Ther. Gaz.*, states that they are of service as antiseptics, antipyretics, analgesics, diaphoretics and diuretics. The tincture, compound tincture, benzoic acid, benzoate of lithium, ammonium, sodium, bismuth and potassium benzoate are the preparations most frequently employed. Internally the lithium benzoate has been used most often by the author. A 1 to 1,000 solution of benzoic acid prevents the development of bacteria and a solution of 4 to 1,000 kills them. Locally he uses the compound tincture in sealing healthy fresh cut wounds in preference to any other dressing. Either the tincture or the acid or the bismuth salt yield excellent results in the treatment of cracked nipples, granulating surfaces, bed sores, chapped hands, anal fissures, and is of special benefit in the treatment of frost bites after they reach the secondary period.

Chronic forms of eczema are benefited by painting the parts with the tincture or dusting them with the bismuth benzoate. He recommends the following combination in the treatment of chancres and chancroids:

℞. Bismuthi benzoatis 3iv 15
Aristol 3i 4
M. Sig.: Apply locally as a dusting powder.

The following combination serves as an excellent dressing in scrofulous skin lesions:

℞. Zinci oxidi
Acidi benzoici, āā.....3ii 8
M. Sig.: To be used locally as a dressing.

Where it is desirable to remove superficial layers of the skin in cases of freckles, or what is classified by the author as "liver spots," the following is recommended:

℞. Tinct. benzoini co. .....℥iss 45
Hydrarg. chloridi corros. 3i 4
Aq. cologne, q. s. .....℥viii 240
M. Sig.: Apply twice daily.

In suppurating and foul-smelling ulcers nothing serves better as a dressing than benzoic acid or its bismuth salt, first cleansing the sore and drying it and applying the powder, over which cotton and bandage should be placed. Internally the chief indication is the treatment of cystitis accompanied by ammoniacal urine. The author gives it in 15 to 20 grain (1.-1.30) doses every two to four hours until the urine becomes acid, after that it may be given three times a day well diluted. It is of value in enuresis of children with neutral or alkaline urine, giving three to five grains after meals three times a day.

In the acute diarrheas of children it is of value given in two-grain (.12) doses every three or four hours to a child of one year or over. It may be given to advantage in chronic bronchitis and in the different forms of influenza. [Mention should also have been made of the value of benzoin in the acute inflammations of the larynx and trachea. It is best administered in the form of an inhalation by floating one or two drams of the tincture on boiling water and instructing the patient to inhale the vapor. By this method the paroxysms can be stopped almost instantaneously, and the patient will drop off to sleep until the next paroxysm, which will gradually become less frequent and less severe.] Trochees containing benzoic acid are also efficient in some cases:

℞. Acidi benzoici .....gr. ss 03
Sodii biboratis .....gr. iss 09
Pulv. acaciæ q. s.
M. Ft. trochiscum No. i. Sig.: One every hour dissolved in the mouth.

Rectal Dilatation for Chronic Constipation and Hemorrhoids.

A correspondent writes: "Can you furnish through THE JOURNAL something authentic about the treatment of constipation and hemorrhoids by the use of rectal (sphincter dilatation)? Various advertisers laud instruments for the purpose. I should like to hear something about the method from a qualified physician."

Constipation is not a condition due to a single cause, consequently no single line of treatment, such as dilatation of the sphincter ani, will cure all cases. A certain percentage of cases are due to overaction or spasmodic action of the sphincter, the spasmodic action being due to a hypersensitive condition of the mucous membrane, caused by slight fissures, superficial ulcers, inflamed follicles or crypts, mild hemorrhoidal condition of the veins, etc. Many of these cases will be relieved of the constipation by dilatation of the sphincter, because the dilatation cures the fissures or inflammatory and irritable condition of the anus, and the spasmodic action of the sphincter ceases. Thorough dilatation under anesthesia is preferable to the use of the so-called rectal dilators flooding the market. A selection of cases must be made based on the conditions present, otherwise frequent disappointment will follow the use of the dilatation treatment of chronic constipation.

Seborrhea of Scalp.

The following combinations, according to an abstract in *N. Y. and Phil. Med. Jour.*, are recommended in the treatment of baldness: After correcting any disturbances of the gastro-intestinal tract and giving the proper attention to arthritic diatheses the following should be used locally to remove the oily secretion:

℞. Sodii boratis 3iii 12
Spts. etheris .....ʒss 15
Aquæ .....ʒviii 240

M. Sig.: Shake and apply locally. The following for the glandular secretion:

℞. Potass. sulphid. .....gr. xv 1
Tinct. benzoini 3ss 2
Aq. destil. .....ʒiii 90

M. Sig.: Locally as a lotion to the scalp.

And to assist in stimulating the growth of the hair, the following:

℞. Lac. sulphuris .....gr. iii 20
Olei ricini .....m. vi 40
Acidi acetici (glacial).....gtt. xv 1
Resorcin 3ss 2
Chloralis hydratis 3i 4
Tinct. jaborandi 3i 4
Tinct. cantharidis 3ii 8
Alcoholis .....ʒvi 180

M. Sig.: To be applied locally.

In the loss of hair following an attack of typhoid fever or pregnancy, the following is recommended:

℞. Spts. chloroformi
Tinct. benzoini
Olei ricini, āā.....3i 4
Olei pini .....m. vi 40
Alcoholis .....ʒvi 180

M. Sig.: Locally to the scalp.

Chronic Diarrhea.

Chronic diarrhea, according to an abstract in *Amer. Med.*, depends on: 1. Autointoxication; 2, an intestinal lesion; 3, insufficiency of gastric digestion. In any case the cause must be treated. In diarrhea due to uremia the patient should be confined to a milk diet. In those cases due to exophthalmic goiter, faradization of the goiter will check the diarrhea. In chronic dysentery a combination of calomel, ipecac and opium is of great value, prescribed as follows:

℞. Pulv. ipecacuanhæ .....gr. i 06
Hydrarg. chloridi mitis.....gr. 1/3 02
Ext. opii .....gr. 1/15 004

M. Ft. pilula No. i. Sig.: Five to eight pills daily.

The author recommends that one or two teaspoonfuls of Rochelle salts be taken two or three times a week in hot water, before meals. In some cases the following powder may be given twice a day before meals:

℞. Pulv. simarubæ .....gr. v 30
Pulv. catechu
Ext. krameriæ, āā.....gr. iv 25
Bis. subnit. .....gr. x 65

M. Ft. chart. No. i. Sig.: One powder twice a day before meals.

If severe colic is present a small quantity of paregoric may be given. Adrenalin is also recommended in doses of five or ten drops of a 1 to 1,0000 solution taken in a little water on arising and before retiring. In diarrhea due to gastric disturbances the proper dietetic measures must be observed. When the mouth is foul in these different forms of diarrhea, Rochelle salts should be taken on an empty stomach, unless there is marked gastric disturbance. A teaspoonful of sodium sulphate in a glass of hot water, to which has been added ten drops of dilute hydrochloric acid, will aid in correcting the condition. It should be taken after meals.

In the treatment of dysentery Roger and Rocaz recommend the use of rectal injections of neutralized hydrogen dioxid in water. The commercial hydrogen dioxid being acid in reaction must be neutralized before using. It may be mixed with an equal quantity of a 4 to 1,000 sodium bicarbonate solution. Another method of neutralizing is by mixing the hydrogen dioxid with Vichy water. The quantity to be injected should be varied to suit the case under treatment. The amount may range from one pint to a quart in adults, and three to six ounces for infants. Two or three injections a day, in benign cases, will be sufficient, which may be increased in severer cases. It is said by this treatment that the pains and tenesmus rapidly diminish and the mucus and blood disappear from the stools. This may be used in any form of enteritis.

In the treatment of chronic dysentery Bjorkman, in *Merck's Archives*, recommends enteroclysmata of silver nitrate, grains 30 (2.00) to the pint (480.00) of water, using five or six pints of such a solution at each irrigation. Severe tenesmus may be relieved by the following suppositories:

℞. Ext. belladonnæ .....gr. iss 10
Butyr. cacao. .....gr. xl 2 65

M. Ft. suppos. No. x. Sig.: One to be inserted into the rectum three times daily; or:

℞. Acidi tannici .....gr. iiss 15
Pulv. opii .....gr. ss 03
Butyr. cacao.....gr. xxx 2

M. Ft. suppos. No. i. Sig.: One per rectum three times a day.

Medicolegal.

Arbitrary Enforcement of Sanitary Code Necessary.—The Court of Appeals of New York says, in the case of People vs. Vandecarr, that, in great cities, where, in certain sections, life exists under crowded conditions that can not be fully comprehended unless seen, and where many articles for table consumption by all classes of the community are liable to pass through processes and conditions little short of appalling unless regulated by law, the full and vigorous exercise of the police power in the interests of the public health and general welfare is absolutely essential. It is quite impossible that every offender against the provisions of the sanitary code should be accorded due process of law, as embracing jury trial and the slow results of the ordinary procedure in the courts. The vesting of powers more or less arbitrary in various officials and boards is necessary, if the work of prevention and regulation is to ward off fevers, pestilence, and the many other ills that constantly menace great centers of population. It is true that there may be provisions inserted in a sanitary code that, after giving the police power full effect, are unconstitutional, violative of well-established legal principles, and subversive of the rights of the citizen. The courts are always open for the correction of such evils. But a requirement of the sanitary code that no milk shall be sold without a written permit from the board of health the court holds is reasonable, and violates neither the federal nor state constitution, and is in accordance with law and long-established precedent.

Liability for Railway Spine.—According to the Supreme Court of Louisiana, the case of Patterson vs. the New Orleans & Carrollton Railroad, Light & Power Company, was brought to recover damages for personal injuries alleged to have been sustained by the party suing in a street-car collision. He and the medical experts on his behalf testified that the injuries so received had resulted in partial paralysis. On the other hand, medical experts called on behalf of the company, whilst conceding that he was not responsible for his condition, and also conceding the possibility that such a condition might have resulted from the causes to which he attributed it, propounded the theory that he was suffering from "railway spine"; that is, that he was the victim of his imagination, and believed that he was paralyzed, whereas he was, in fact, affected by no physical ailment. Under these circumstances, the court says, that it had to choose between the alternatives of holding that the party was actually suffering from the physical disability of which he complained, or of holding that, by reason of a mental conditon for which he was not responsible, he believed that he was suffering from that disability, and as a consequence, for all practical purposes, was in the condition in which he believed himself to be. But it was not assured that he was

any more likely to get well in the one case than in the other, and as, in either case, it was the company that was responsible for his condition, it says that it was not clear that it made any difference, so far as the claim here made was concerned, which alternative was chosen. In other words, it says that as it did not appear that he was any more likely to get well in the one case than in the other, and as, in neither case, was he responsible for his condition, it was not clear that it would make any difference, for the purposes of the present claim, whether he was really paralyzed or was merely laboring under a fixed belief to that effect. But, considering the whole evidence, the court reaches the conclusion that the company's theory was not sustained, and affirms a judgment against it for $4,000 damages.

Holding of Postmortem Without Notice to Company.—In the case of Loesch vs. the Union Casualty & Surety Company, an action brought on an accident policy by a mother to recover for the death of a son insured for her benefit, the Supreme Court of Missouri, Division No. 1, says that, on the day after the son's death, the physician in attendance told the mother that he desired to hold a postmortem examination, to which she assented, or, at least, made no objection. He called in some other physicians to assist him, and they made a postmortem examination. After it was done, and the body was sewed up, the physicians came out of the room, and then the mother handed the attending physician the policy in suit, and asked him what she should do in regard to it. He examined it, and discovered a clause declaring that, if a postmortem be held without notice to the company in time to have its medical adviser present all claims under the policy should be forfeited. He went immediately to the office of the company, and notified them of what had occurred, and on behalf of the mother offered to hold another postmortem with their medical adviser if they so desired. But they expressed no such desire, and the mother, after holding the body until the next day, caused it to be buried. The court says that it is satisfied that the holding of the postmortem examination without notice to the company, under the circumstances shown by the evidence in this case, did not have the effect to forfeit the mother's rights under the policy. A clause of forfeiture is not to be strictly construed in favor of the company in such case. On the contrary, whilst it should be given a reasonable interpretation, yet the inclination of the court should be against the forfeiture. The design of this clause in the policy was to enable the company to learn the cause of the death of the insured, as that cause might be shown by a postmortem examination, if one should be held. Whatever such an examination might show, the company was entitled to an opportunity to know. It is a reasonable requirement under reasonable interpretation, and a violation of its terms under circumstances reasonably showing disadvantage to the company would work a forfeiture of the policy. But there was nothing in this case to indicate any such disadvantage. In the first place, it was very doubtful if the mother was responsible for the act. If it occurred without her knowledge or consent, it would be no defense to the suit. She testified that she did not know what the word meant, and did not know what the physicians were doing. But, however that might be, as soon as the attending physician saw the policy and read this clause, which was immediately after the postmortem had been held, he went to the office of the company, and informed them what had been done, and offered to allow them to make a reexamination, as before stated. There was no suggestion in the record of any fact or theory which would tend to show that a re-examination of the body at that time would not disclose to the eye of the company's surgeon everything that the first disclosed to the physicians who made it. The court does not say that the first examination might not have disclosed facts that could have been hidden from one making a second examination; but there was no such suggestion in this record, and it was not led, therefore, into such an inquiry. Wherefore, the court holds that the fact that the postmortem examination was held without notice to the company was no bar to the mother's action under the circumstances disclosed by the evidence in this case.

American Medicine, Philadelphia.

September 12.

1 *Labia Urethræ and Skene's Glands. (To be concluded.) Howard A. Kelly.
2 *A Study of Uncinariasis in Porto Rico. (Concluded.) Bailey K. Ashford and W. W. King.
3 *Splanchnoptosis Caused by Omental Adhesions. Daniel H. Craig.
4 *On the Condition of the Blood in Rheumatoid Arthritis and Osteoarthritis. William G. Erving.
5 *Eclampsia. Hubert Richardson.
6 Infantile Tetany. H. C. Masland.
7 Some Notes on Nassau. Samuel A. Fisk.

1. **Labia Urethrae and Skene's Glands.**—In this article Kelly describes an anatomic formation which has apparently not been noticed by previous writers, that is, the mucous folds which surround the female urethral orifice and apparently have a protective influence against noxious vaginal discharges, etc. He illustrates various forms of these and their changes with senility. In the second part of his paper he begins the description and history of Skene's glands, the function of which is to exercise an office for the urethral orifice precisely similar to that of the vulvo-vaginal glands in relation to the vaginal orifice, to provide a lubricating fluid to protect the delicate mucosa from harmful attrition.

2. **Uncinariasis in Porto Rico.**—The treatment of uncinariasis is detailed by Ashford and King. They have come to rely on thymol given in the morning on an empty stomach in doses of 30 gr. repeated after two hours and preceded by a full dose of magnesium sulphate. If the bowels had not moved by noon another dose of salts was given. They have seen no bad effects from thymol, though such might be expected if alcoholic liquors were taken with it, as in the case reported by Thornhill. Caution, however, must be used in treating children and patients with great debility, especially in weakened heart conditions, and the dose reduced in proportion and heart stimulants and tonics given. Thymol should be repeated every eight or ten days until the ova have ceased to appear in the stools or longer if the percentage of hemoglobin does not rise. The best results in blood regeneration have been obtained with large doses of Blaud's pills and Vallet's mass. Some benefit was also derived from the use of adrenalin chlorid used as a circulatory stimulant in cases of weak heart. Of the patients treated 58 were completely cured, 25 were improved, 13 of whom are still in the hospital, and will be cured unless unforeseen accidents occur; 5 are not improved, but 3 of these are tuberculous; 6 died of anemia, 3 of tuberculosis, and 1 of pernicious malaria when nearly well of the anemia. The details of the cases are given.

3. **Splanchnoptosis Caused by Omental Adhesions.**—Craig reports three cases, and warns in the surgical treatment of these conditions against injury to the omentum. Traction on this in case of adhesion might tear the colon or do other harm.

4. **The Blood in Rheumatic Arthritis and Osteoarthritis.**—Erving reports the results of an inquiry into the condition of the blood in these diseases in some 40 cases, and finds that it is not such as would be expected in diseases of such a general wasting nature. The formed elements of the blood are practically unaffected. The slight leucocytosis noted seemed to have no relation to the duration or severity of the symptoms.

5. **Eclampsia.**—Richardson thinks that from the physiologic facts known, the similarity of symptoms of eclampsia to those of hypothyroidea, and the observations of Lange on pregnancy, it seems probable that a considerable proportion of cases of eclampsia are due to thyroid insufficiency.

8 *The Value of Confirmatory Cultures in Diphtheria. John S. Billings, Jr.
9 The Roentgen Ray as a Therapeutic Agent. Cyril Fulton.
10 *Surgical Shock, with Special Reference to the Solar Plexus as a Factor. L. J. Dandurant.
11 *The Preparation of the Patient for Nose and Throat Operations Under Local Anesthesia. Nathan G. Ward.

12 *The Leucocytes in the Summer Diarrhea of Infants. John Zahorsky.
13 *The Prognosis and Orthopedic Treatment of Acute Anterior Poliomyelitis. (Concluded.) Walter G. Stern.
14 *Straight Splints in Elbow Fractures. J. Hubley Schall.

8. **Diphtheria.**—The usefulness of confirmatory cultures in diphtheria is discussed by Billings, who finds that while in a certain small percentage of cases the diphtheria bacillus fails to appear in the first cultures, the failure is generally due to a conjoined infection with the septic micrococci. Aside from these cases, the statement that the case is probably not diphtheria can be made on one negative culture up to the tenth day of the disease. Valid reasons for requesting a confirmatory culture in negative cases are: 1. Where there is no growth whatever on the culture media; 2, where there is complete contamination and liquefaction of culture media, in cases which are clinically diphtheria; 3, cases where there are suspicious bacilli; 4, in croup cases where the membrane is limited to the larynx and the duration of the disease is less than five days. Dryness of culture media, scanty growth and the recent use of antiseptics with satisfactory growth of other organisms than the diphtheria bacilli, do not alone furnish sufficient grounds on which to request a confirmatory culture. These regulations govern the system of second cultures in the diagnosis laboratory of New York City.

10. **Shock.**—Dandurant notices particularly the type which he calls the solar plexus shock characterized by a lack of symptoms, except rapid and erratic heart action and pulse. He thinks in the majority of these cases the perverted condition of the solar plexus is a factor in the production of the phenomena.

11. **Nose and Throat Operations.**—The importance of preliminary treatment for nose and throat operations under local anesthesia is insisted on by Ward, who outlines it as follows:

1. Local treatment, to free the nose and nasopharynx from mucus and relieve congestion.
2. Laxatives, diaphoretics and diuretics, to stimulate elimination.
3. Tonics, to tone up the nervous centers and restore general functional activity.
4. Atropin, to prevent reflex inhibition.

These precautions will assure less shock, prevent complications and hasten repair.

12. **Summer Diarrhea of Infants.**—Zahorsky concludes with Knox and Warfield that the leucocyte count in this condition is too variable to be of special diagnostic importance, but holds that the differential count is extremely valuable in the estimation of the intensity of the intoxication. The normal ratio of the polymorphonuclears to the lymphocytes in healthy infants is 2 to 3 or 4. In gastroenteric disease this ratio becomes changed; the leucocytes gradually increase and the lymphocytes diminish, when the ratio becomes 1 to 1, 4 to 3, etc. This predominance of polymorphonuclears, therefore, reveals an intensity of the morbid process and means that the baby is pretty sick, whatever other signs may indicate.

13. **Acute Anterior Poliomyelitis.**—The orthopedic treatment of this condition is described by Stern, who insists on the importance of treatment, if only to prevent deformity, and gives details as to tendon transplantation, arthrodesis, etc.

14. **Elbow Fractures.**—Schall advocates the use of straight splints extending from the upper third of the arm to the wrist with slight divergence at the elbow, the hand and arm being kept supine. To prevent the olecranon from becoming displaced, small strips of adhesive plaster were passed just above the fragments down and around the splint. He objects to complicated fracture dressings in injuries about the elbow, and to the extremely flexed position.

22 Later Impressions of the "Non-heredity of Acquired Characters." Lewis S. Blackwell.
23 *Therapeutics of Potassium Copaibate. Louis Kolipinski.

15. **Infantile Scorbutus.**—Two cases are reported by Rotch to impress on the profession the great care that should be taken to differentiate between the advanced bone lesions of this disease and those of osteomyelitis and osteosarcoma. In the first case, three separate operations had been performed and a large portion of the tibia removed. The diagnosis of infantile scorbutus was suggested by him in consultation and orange juice recommended, followed by the steady improvement in the condition of the child. In the second case scorbutus was diagnosed as probable, and a diet of plain cow's milk and orange juice employed with excellent results, though there was very marked swelling of the bone suggesting the presence of osteosarcoma, and it had been suggested that amputation for osteosarcoma would be needed.

16. **The McGraw Elastic Ligature.**—Maury has employed the McGraw elastic ligature in such a way as to insure its "punching out," instead of leaving a linear aperture which may be broken up by adhesions. He makes a square stitch, the technic of which is described as follows:

Decide on the size of the square desired, and, after approximating the surface, gut and gut or stomach and gut so that there may be no unnecessary tension, place a Lembert stitch of silk to join the two viscera at each of two points destined to be the diagonally opposite angles of the completed square. These stitches will hold the parts together and will serve as guides for the introduction of the ligature. The needle is introduced into one of the apposed viscera at a point selected for one of the remaining angles and brought out beside one of the guides. From here it is passed through the opposite organ, care being taken that the needle thoroughly pierces the mucous membrane—which is somewhat resistant in a dog but not so in a pig—and out again at a point diagonally opposite the starting place. From this point to the point of beginning the steps are directly reversed, viz.: the needle re-enters the first viscus, emerges at the first guide, re-enters the second viscus and emerges as nearly opposite the starting point as possible. The stitch is then just half done; two sides of the square are completed, and the arrangement of the elastic ligature may be correctly represented by a figure 8 bent in the middle. The remaining two sides of the square are completed in the same manner, care being taken to make the distal loops of the two figures of 8 interlock.

He gives and illustrates the results of experimental work with this on dogs and offers the following conclusions:

1. The McGraw elastic ligature can be so inserted as to "punch out" as large an area of the juxtaposing walls as may be desired, with at least as much certainty and with greater safety than the Murphy button.
2. That the margins of such openings are smooth and not unduly cicatrized.
3. That the elastic ligature may remain *in situ* after punching the openings, although this is less likely to happen if tied with iodized catgut.
4. That such retention in the mucosa of so soft a material is not apt to be harmful or permanent.
5. That the time required is not sufficiently increased to render the use of this technic impracticable.
6. That perhaps enough has been suggested to stimulate further research by others, so that the actual facts in these most interesting problems may shortly be brought to light.

17. **Empyema.**—The apparatus suggested by Usher consists of a metal box with a screw cap arranged for the application of suction, etc., and fastened down to the body so as to exclude air by means of rubber plaster or bandage rubber.

20. **Non-Physical Therapy.**—Baker thinks that quacks and irregulars, honest and dishonest, are defining a field of non-physical therapy, which needs investigation by the highest skill and training and promises favorable results.

21.—See abstract in THE JOURNAL, xl, p. 1669.

23. **Potassium Copaibate.**—This preparation, which Kolipinski finds decidedly advantageous, is prepared by mixing 8 parts by weight of copaibate with 1 part of potassium hydrate in a small quantity of water. On stirring, saponification results. By standing three or four days, the volatile oil stays at the top, potassium copaibate in the middle, and the lowermost layer is the residue of uncombined alkali in water. It is gelatinous at 50 F., thick and oily at 63 F., and quite liquid at 70 to 80 F. Its reaction is alkaline. It dissolves rapidly in alcohol, ether, and chloroform. It is best given in gelatin capsules in doses of 50 to 150 gr. per day. Four to twelve capsules represent the average daily amount. The average man will tolerate two capsules three times a day; robust men twelve daily, and those easily purged will not be able to take more than four for some length of time. Its by-effects are similar to those of the crude drug,

though less severe. It has all the virtues commonly ascribed to copaiba, with special ones due to its solubility, and it is more palatable than the latter. It reduces the danger of complications to a minimum so that gonorrheal bubo, epididymitis, cowperitis, prostatitis, vesiculitis, cystitis and stricture are seldom seen to arise.

24. **Cancer of the Intestine.**—Gage first notices the unfavorable statistics of Fitz and then reviews the results of Korte, McEwen and Krönlein, which he thinks to a certain degree are favorable, especially in cases of ileocecal cancer. Four cases are reported by him, two of which were apparently quite successful. In 2 the acute intestinal obstruction was the first indication of the existence of any serious trouble, and he remarks that the diagnosis in these cases can not be made without exploratory incision, and when symptoms suggest a chronic appendicitis, or obstruction, its desirability is evident. If the disease, however, has invaded the mesentery, lymphatics, etc., he would not operate further, and he would confine the use of the exploratory incision to cases in which the earliest symptoms were those of acute intestinal obstruction, appendicitis and chronic intestinal disturbance where there is a clear presumption against very advanced malignant disease. As regards colostomy, while it may be useful, he thinks it can have only imperfect and merely temporary good effects.

25. **Ovarian Prolapse.**—Craig's paper makes the point that reflexes or contrecoup from above in coughing, etc., with rigid chest and abdomen are responsible for ovarian prolapse, and details some of his experiments to determine the amount of force thus produced. He finds that a pressure of 14 ounces causes complete prolapse and that the force engendered by coughing is slightly in excess of that required. The wearing of corsets has much to do with producing the bad results. He suggests that the congestion of menstruation in conjunction with that of respiratory diseases is always harmful and should be guarded against even in the nulliparous, and that corsets had better be proscribed during any severe or long persistent cough-accompanied lesion, especially during the catamenia. By requiring the patient to assume the prone position for a few minutes after violent coughing, disengorgement of the pelvic vessels is favored and gravity assists the ovarian supports. If ovarian or pelvic involvement is suspected, the pelvic respiratory massage suggested by Williams may be of advantage. This consists in having the patient assume the genu-pectoral or knee-elbow posture and aspirate the pelvic vessels by slow force-expiration about fourteen times per minute.

31 Ancient Jibes at the Doctors. Jonathan Wright.
32 Some Experiences with Ichthyol in Puerperal Fever. J. D. MacPherson.
33 *The Surgical Treatment of Colitis. C. L. Gibson.

29. **Post-Typhoid Sepsis.**—Delafield illustrates cases of typhoid with relapses during convalescence, rigors, chills, etc., which he thinks indicate that at the end of typhoid fever there may come in a new infection resembling the streptococcus infection, either mild or severe. He suggests that with care this can be usually distinguished from typhoid, and the practical point is that it calls for different management. The best results are obtained if the patients are fed and taken out of bed.

30. **Purulent Arthritis.**—Berg points out the indications for operation in acute joint disease, the necessity for careful blood cultures beforehand as an essential for treatment and the importance of evacuation and drainage in case of suppuration. In the mild forms there is very little tendency to the destruction of the synovial membrane or ligaments, and septic symptoms are not severe, but in the severer cases there is more or less destruction. For the milder grades the old methods of single or multiple incision of the joint, evacuation of the exudate and drainage give very good results and may restore the joint to perfect function. In the severer cases he follows the plan of Mayo of making a transverse anterior incision through the patella into the joint, with partial dislocation of the femur and the tibia by extreme flexion and dry packing of the synovial cavity. Of course, this destroys the future function of the joint, but this can not be avoided in any case, and he suggests from his experience that good results may follow the same treatment in the other large joints, especially the elbow, ankle and wrist. In the after-treatment of arthritis immobilization of the joint should be employed until the acute inflammation subsides and then passive motion cautiously applied. Forcible passive motion is to be deprecated. For the periarthritis, the Priesnitz cold pack, combined with douches and massage are employed with satisfactory results. The pseudoarthritis and periarthritis leave no ultimate impairment of the joint function, nor do the serous, serofibrinous or catarrhal types of arthritis, though prolonged drainage of the joint for pyarthrosis is usually followed by fibrous ankylosis. This, however, varies, and he has had cases where the joint function was completely recovered.

33. **Colitis.**—Gibson's method, suggested in 1902, is briefly redescribed. It consists particularly in reproducing the technic of Kader's gastrostomy, making a valvular opening into the intestine and introducing a drainage tube through which treatment can be carried on. When it is removed the valvular arrangement completely closes it, and to obtain permanent closure of the fistula when required it is only necessary to discontinue the treatment by omitting to pass the catheter into the gut. The Weir modification of this, with the use of the appendix, has the apparent advantage of making the simple operation still simpler, but the valvular formation is wanting and the after-treatment is less agreeable. Gibson says that the results of this operation have been such as to justify the hope of marked amelioration or cure of the symptoms, while it offers the advantage that it is devoid of every disagreeable feature of an artificial anus. It calls for only a short confinement to bed. If a prolonged course of treatment is required, it may be carried out if necessary by the patient himself. A change of climate, so often beneficial, is made possible. Its performance is perfectly simple and safe. The intermuscular incision greatly reduces the risk of a subsequent hernia, and the prompt closure of the fistula is certain and spontaneous.

41 *Suburethral Abscess, or Incomplete Internal Urethral Fistula; Report of Three Cases. C. Jeff Miller.
42 The Card System in Gynecology. H. J. Boldt.

38. **Urine Changes in Pregnancy.**—Whitney and Clapp describe elaborately their methods of urine examination, and proclaim that there is an unmistakable tendency during pregnancy for a lessened output of urea nitrogen, together with a

slight increase of ammonia nitrogen as compared with the non-pregnant condition. In eclamptic women urine analysis shows that the essential change consists in a decrease in the percentage of nitrogen which is eliminated as urea, with an increase of the amount which is precipitated by phosphotungstic acid and readily decomposed by heating with sulphuric acid at a temperature of 160 C. Unfortunately our knowledge is incomplete as to the exact nature of these substances. In some cases, they think, the loosely combined nitrogen is derived from ammonia and in others it may be attributed to some as yet undetermined antecedent of urea. The variability of the ammonia increase in the different cases is attributed to the fact of the imperfect metabolic processes, the proteid destruction not proceeding as far as the ammonia stage, while in other cases the ammonia is retained either in the body fluids or stored up in excessive quantities, especially in the nervous system. We are still in the dark as to the cause of the alteration in metabolism that characterizes eclampsia. It is possible that the hepatic function may be in some cases at fault; the fact that the urinary changes last after delivery for some time would seem to indicate that the hepatic lesions do not immediately disappear after delivery. Further study will be required to fully elucidate the question, and to determine whether these urinary changes are constant enough to be of value in predicting the occurrence of eclampsia.

39.—See abstract in THE JOURNAL, xl, p. 1526.

40. **Conservative Gynecology.**—Manton reviews his experience in 62 conservative operations on the uterus and appendages in 53 patients. There have been 94.3 per cent. symptomatic cures, 5.6 per cent. of failures with no deaths. The mortality seems to have certainly been better in these cases than with the ordinary radical operations. The general health of the patients and the maintenance of normal function of the reproductive organs are also to be taken into account. Pregnancy has occurred since in 5.6 per cent.

41. **Suburethral Abscess.**—Miller describes three cases of this condition, one apparently due to an urethral diverticulum, one possibly of gonorrheal origin, and one probably originating in Skene's glands or in one of the urethral crypts. The symptoms are principally painful urination, sensation of heat and distress. Palpation will detect the thickened edges if the trouble follows periurethral inflammation. The urethral speculum is of use in revealing the locality of the pus discharge. The treatment that he advises is surgical; prompt incision and perhaps excision of the sac. After incision of the sac, a retention catheter should be worn for a time or the bladder at least emptied at regular intervals with a soft rubber catheter to prevent contamination of the wound.

43.—This article appeared elsewhere. See THE JOURNAL of July 25, ¶81, p. 284.

44. **Traumatic Insanity.**—Richardson does not recognize any special symptomatology of mental disturbances from trauma, though he describes a certain class of cases that may be the result. Many of the symptoms, however, belong to the neurotic rather than the psychic type, and these are intermingled in nearly all cases. Even in the purely functional neuroses there is the psychic disturbance, the relation of the *ego* to the environment is disturbed, the judgment is at fault, the emotions are deranged and the mental strength somewhat diminished. In the great majority of cases, moreover, there is a complication of a prospective damage suit which in some cases is the principal cause of the disorder, though the patient may be perfectly honest. Settlement of the suit will sometimes entirely remove the trouble without any evidences of intentional malingering.

45. **Brain Surgery in Epilepsy.**—Spratling gives the results of operation in 33 cases of epilepsy. In 21 there was no improvement; in 8 the attacks lessened, but operation was only a part of the treatment and not the most effective in his opinion. In 3 the condition was aggravated. In one a gynecologic operation seemed to produce recovery, the uterus being a retention cyst it was removed with all appendages. The patient has been free from the disease since that time. She had had an operation on the brain for traumatic trouble, to which the epilepsy was attributed, but this did not relieve, as the epilepsy was evidently the result of an autointoxication. In none of the cases was operation itself fatal, which is in contrast to the results in idiocy, where there is considerable mortality. He also reviews the effects of surgery in 111 cases of idiocy. The improvement was comparatively insignificant. He says surgical interference may be still used in isolated cases of idiocy, but it seems clear that it is slowly finding its position in rational surgery along a plane far lower than what at first seemed possible at the time of its inauguration.

46. **Tent Life for the Insane.**—Wright and Haviland report very encouraging results from the care of the insane in tents, aiding not only the tuberculous patients, but as also of use in other forms of insanity. They think it is worthy of application as a therapeutic measure in the modern treatment of insanity.

47. **Hereditary Factors in Epilepsy.**—Doran analyzes a number of cases of epilepsy and calls attention particularly to the following points noted in the study of heredity in the histories of 1,300 epileptic patients in a public institution:

Though it was impossible to secure data in many cases, yet a definite history of the various neuroses of alcoholism was found in 46.5 per cent. of the total. Alcoholism, epilepsy and insanity combined were responsible for 38.6 per cent. of the total cases, and paternal alcoholism existed in 18 per cent. of all cases. Diseases other than those connected with the nervous system have little hereditary influence in epilepsy. The age of onset is influenced by the character of the heredity.

48. **Insanity in California.**—California is now just a little over fifty years old. In its beginning insanity was almost unknown, but in 1860 the ratio was 1 to 1,000, in 1870 it was 1 to 500, and at present the registered insane number 1 to 260 of the general population. There are a number of reasons given by Robertson for this large ratio: One is the universal state care, bringing out all the cases; another is the large proportion of mental derangement in the foreign-born population, due to change of environment, homesickness, etc. The foreign born do not comprise more than 25 per cent. of the population, but they supply 57 per cent. of the insane, and immigrants from other states also furnish a considerable proportion. Heredity does not figure conspicuously, but the mild climate favoring long hours of working, etc., the briefness or absence of vacations, etc., all have their influence. Education and age seem to have but little necessary effect, but the disproportion of men to women is remarkable. Of the 5,494 patient, 3,448 are men. He speaks particularly of beer drinking as a cause. California beer contains 3 to 5 per cent. alcohol and the drinking of twenty steins, which is not unusual for some, means the absorption of 12 ounces of alcohol. Neither whiskey nor wine, though they may be more stimulating, are so insidiously poisoning. In conclusion he notes the difficulties of ascertaining the correct statistics for comparison as in many other states the number of insane reported is evidently only those acutely insane, those that happen to be under special care, or those who have been committed as deranged.

49. **Insane Delusions.**—Wherry sums up an insane delusion as an idea born in subconscious cerebration; projected into consciousness in times of stress; believed implicity and strenuously defended by the originator, but which no one else will accept as true.

50. **Cerebrospinal Fluid in Paresis.**—Kramer has studied the composition of the cerebrospinal fluid in 11 cases of paresis, 13 cases of dementia precox and several cases of other forms of insanity, counting the number of leucocytes. He finds that the results agree with those of Joffroy and Mercier in the greater prominence of leucocytosis in paretics. He thinks that the method may be a valuable one in making the differential diagnosis in doubtful cases.

51. **The Criminal Insane.**—The care of convicts and criminals committed as insane is discussed by Allison, who urges greater vigilance on the part of prison officials to detect insanity, and the erection of special hospitals for the criminal and dangerous insane and the commitment thereto by judicial order of all that belong to that category that they may be kept until fit to be released. Lastly, in all institutions for the care of criminals and defectives there should be greater vigilance in ascertaining the personal history of each inmate with a view to detecting and deporting all aliens who may have entered the country in violation of the immigration laws.

53.—See abstract in THE JOURNAL, xl, p. 1669.

54. **Exophthalmic Goiter.**—Deaver concludes as follows from his observations and the study of others' work:

1. That, as surgical treatment is recognized as the most satisfactory in exophthalmic goiter, so is complete bilateral cervical sympathectomy to be considered the operation of choice. 2. The operation should not be performed during the height of psychical irritation or tachycardia, nor by an operator who has not an absolute knowledge of the anatomy of the neck and a large experience in dealing with difficult operative procedures, or the means at hand to cope with any emergency. 3. The results of the operation are far better than the other procedures, the mortality is much lower and, in cured cases, the improvement is permanent. 4. In chronic glaucoma, especially after the failure of iridectomy and sclerotomy, this operation may restore vision completely, unless the disease is too far advanced, with absence of light perception. 5. In recurring attacks of epilepsy, sympathectomy should be resorted to. The results warrant the operation. Jonnesco has reported 12 cures and 4 improvements in 49 epileptics operated on before 1899.

56. **The Inferior Ethmoidal Turbinate.**—Lothrop's article is largely anatomic, describing and illustrating the conditions in the nose with special reference to cell formation in the inferior ethmoidal or middle turbinate, which may in certain cases produce trouble. The treatment of the condition is surgical.

57. **Gradual Occlusion of Large Arteries.**—Stratton has experimented on dogs with gradual occlusion of large arteries with special reference to its feasibility as a preliminary to permanent ligation, extirpation of tumors and other operative procedures. While it is impossible to exactly compare the conditions in lower animals with those in man, he thinks the method has its advantages and may be of decided value where closure of the abdominal aorta is concerned, not, however, for permanent ligation, as that would be fatal, but in arteries of lesser caliber, except for special reasons which might determine its use for aneurism. The forcible or weak blood current, together with the presence or absence of arteriosclerosis and the accompanying lack of general tissue-vigor, would determine the desirability of adopting gradual closure or ordinary ligation.

58.—See abstract in THE JOURNAL, xl, p. 1595.

59. **Retroduodenal Choledochotomy.**—The method proposed by Berg is practically as follows: A small, round, hard cushion should be placed under the lower dorsal region of the patient, throwing the parietes forward. Next, abdominal incision through the right rectus from the costal arch to the umbilicus. Then free exposure of the descending portion of the duodenum, separation of adhesions, division between the two ligatures if vascular. The liver is drawn upward by a broad retractor, the stomach pushed over to the left and the transverse colon downward by gauze compresses and held away by the assistant. Next, mobilization of the descending duodenum: Three or four cm. external to the right border of the duodenum, the posterior parietal peritoneum is incised in a longitudinal direction from the flexure of the duodenum above to the transverse mesocolon below. Then with the finger the internal or left portion of the divided peritoneum is elevated from the parietes up to the right duodenal border; the finger is passed behind the duodenum, gently separating it up to its inner border, from the vertebræ, inferior cava and aorta. It is now only loosely fixed at its flexure above, at the transverse mesocolon below, and along its inner concave margin, and is easily rotated to the left around a longitudinal axis passing through its inner margin. This brings its posterior surface and the retroduodenal and papillary portions of the common duct anteriorly, and affords an excellent exposure. The duodenal branch of the pancreatic duodenal artery lies anterior to the duct about one-fourth of an inch. The accompanying vein lies just behind the duct and sometimes a branch of the vein crosses it. The superior mesenteric branch of the portal vein is considerably internal to the duct and the vena cava posteriorly to it. The duct is readily recognized and can be grasped between the fingers, incised, and impacted calculi removed. The site of incision into the duct should be covered by a narrow wick of gauze and the descending duodenum allowed to fall back to its original position. If drainage of the common bile and hepatic duct is required, the common duct is incised in its free portion in the gastrohepatic ligament, and a drainage tube inserted into this opening. The incision into the retroduodenal portion of the duct can be easily sutured, though this should not be necessary. This operation works well on the cadaver, and he asks those who think well enough of it to try it and report results.

60. **Cancer.**—Rogers suggests as a theory of the etiology of cancer that it is due to enzymes assimilating from the blood the carbohydrate to form the glycogen necessary for the life and growth of the cells, and by an excess of nutriment causing outgrowth beyond the natural limits in the shape of malignancy. That there is an enzyme in cancerous tissue has been shown by Buxton in a yet unpublished document, though he does not affirm that its amount is in proportion to the malignancy, but this the author suggests as an inference. He applies this theory to the clinical facts and reports experiments which are as yet, however, incomplete.

61. **Actinomycosis in Man.**—Maass offers the following as facts or disputed points made prominent by the cases of actinomycosis which form the basis of his paper:

1. The diagnosis of "primary pulmonary actinomycosis," even in the absence of all abdominal symptoms, must remain doubtful without a postmortem examination. 2. In abdominal, as well as in pulmonary actinomycosis, the patient should be closely questioned regarding any previous more or less indistinct symptoms of appendicitis and sores at the anus. 3. Fecal concrements found in the appendix in cases of actinomycosis should be microscopically examined. 4. In actinomycosis following typhoid-like symptoms, a Widal test should be made. 5. At the postmortem special attention must be paid to intestinal scars, which may easily avoid detection. 6. Experiments and clinical observation indicate that the fungus can not enter the human or animal body without a wounded surface. 7. Must the wounded body also be the carrier of the infectious material, or can infection take place secondarily through a granulating accidental wound or the chronic ulcers described? 8. Human actinomycosis of the skin or actinomycosis of the jaw in pasturing cattle may offer a suitable object for investigation in regard to point No. 7.

66 Idiopathic Bilateral Atherosis. V. Krafft-Ebing.
67 *Mixoscopic, Adolescent Survivals in Art, Literature and Pseudo-ethics. (To be continued.) James G. Kiernan.

62 (and 172). **Unrecognized Toxic Insanities.**—Crothers holds that toxic insanities, especially from drugs and spirits, are increasing. This is evidenced not only by the records of courts and hospitals in the degenerate classes, but also in the higher walks of life where unexpected crimes or aberrant conduct startles society. When these are studied they are found to be dependent largely on alcohol and drug habits. Close study, he says, reveals a distinct origin, progress and development of these degenerative psychoses with progressive brain and nervous disorders. Alcohol is the most prominent of these causes, but it is a probable fact that a large per cent. of all insanities occurring in the more well-to-do classes are directly or indirectly the result of alcohol or drugs, and are largely unrecognized except in the later stages, and then often do not attract attention except by accident. The changes in the conduct, character, habits, etc., in alcohol and drug users can only be explained as true psychoses. He remarks that fully one-fourth of medical practice in this country among the better off is directed to the correction of injuries produced by these habits, though the actual psychologic condition is often unrecognized and unknown. Among the lower classes it is evident that a very large proportion of the crime and insanity is due to this cause.

63. **Acute Hallucinosis.**—In this lecture Wernicke describes a case of hallucinatory paranoia, a type of psychosis, under this name, and which must be differentiated from delirium tremens from the simple acute psychoses of apprehension and from cases of chronic development. In former writings he has called it chronic hallucinosis. The course of the disease is characterized by acute, rapid onset and the descending condition of its curve. Its treatment is only possible in the acute stage at an insane asylum, and under these circumstances the prognosis is favorable, but it is quite frequently only the initial stage of a rapidly progressive sensory psychosis, which, he says, deserves the name of acute progressive hallucinosis.

64. **Aphasia.**—In this lecture Hughes notices the medicolegal bearing of aphasia, taking the view that if a patient is conscious of his crippled condition and attempts to compensate for it, he is capable of making legally valid wills or documents. The severe forms of altered speech utterances due to irritation of the speech centers or their psychologic areas are also alluded to, such as the gibberish of idiocy, but more especially the irritative functional sort of the disorder involving the speech center, such as a tendency to verbal autorhythmic forms of speech repetition. The repetition of a word, tone or phrase is more characteristic of the transitory functional disorders than of organic speech center damage. They are mostly examples of mental aberration with coexistent speech center rhythmic excitation, and we should be guarded and not mistake the counterfeit for the genuine aphasia.

65. **Hydrocephalus Internus.**—Senn reports a case of attempted subcutaneous drainage of an internal hydrocephalus, the object being to avoid infection. The patient died rather unaccountably—no postmortem was allowed—though marked improvement seemed to follow the operation. The case indicates to him, however, that subcutaneous drainage is preferable to open drainage, and proves conclusively that the cerebrospinal fluid is quickly absorbed by the connective tissue elements as soon as it escapes from the ventricle.

67. **Myxoscopic Adolescent Survivals.**—Kiernan, in this installment of his article, notices the cases of Pope, Rousseau and Sacher-Masoch as instances of this type. The histories and comments are interesting and instructive. They illustrate, he thinks, how adolescent storm and stress often dominate mentally long after adolescence, even in those who have apparently passed through the period without nervous breakdown. Many instances of morbid mentality show that the relationships between genius and idiocy are of this kind.

69 *Tinnitus, with a Plea for Its More Accurate Musical Notation. James A. Spalding.
70 The University Clinic for Diseases of the Ear and Throat in Rostock. O. Koerner.
71 Three Clinical Communications to Otology (Scotoma Auris, Syncope, etc.).

68. **Deafness and Accident Insurance.**—Spalding notices his own case and concludes from his personal experience and study that owing to the greater care the deaf person takes of himself because of his defect, and his better perception of sounds in street noises, than in the case of those who can hear, and also in his better bone conduction by which he readily becomes aware of approaching danger, he is as good a risk against pedestrian accidents as are those who can hear well.

69. **Tinnitus.**—Spalding has studied the musical pitch of tinnitus and suggests the usefulness of testing this. He thinks in some cases it may be of practical value both in the relief of the condition and, if it is true, as Zaufal has suggested, that there is a certain set of auditory cells more easily affected by irritation than others, we can probably in no better way discover what those cells are and where they are situated in the labyrinth than by studying and investigating their location-pitch as exhibited by their tinnitus when they are irritated.

77 Report of a Case of Purulent Metastatic Ophthalmia in Meningitis, Giving Rise to Meningitic and Sympathetic Symptoms After Thirteen Years; Enucleation; Recovery. C. Zimmermann and Brown Pusey.

72. **Accommodative Asthenopia.**—Bull argues that the so-called accommodative asthenopia of Donders is more a disorder of function of the motor nerves of the eye than of the accommodation or refraction. He asks whether the name accommodative asthenopia should be maintained, and whether the term muscular asthenopia should not be limited to cases of insufficiency of the internal recti.

73. **Intracapsular Irrigation.**—Riek advocates the use of intracapsular irrigation in cataract operations and finds that he is in accord with McKeown in favoring this method. His conclusions are in substance that the introduction within the eye of sterilized saline solution is harmless, and that the removal of cortex is a mechanical process and regulated by ordinary physical laws, and that from the anatomic structure and conditions irrigation is more efficient in removing cortex than any other method. It also removes blood and bubbles of air. It shows the condition of the capsule, gives tone to and replaces the iris and is effectual in making the toilet of the wound. Free irrigation by the nozzles may be practiced without fear. The irrigation does not tend to cause prolapse of the vitreous, and secondary operations are required in a very small percentage of cases.

Journal of Eye, Ear and Throat Diseases, Baltimore.

July-August.

78 *The Bacteriology of Acute Otitis Media. E. C. Ellett.

78. **The Bacteriology of Acute Otitis Media.**—From a study of cases, including some 40 in private practice, in which bacterial determinations were made, Ellett concludes that all the usual varieties of pyogenic organism are associated, apparently as the cause, with acute otitis media. We can not tell from a bacteriologic study which cases are likely to prove severe and of long duration or mild and brief. A classification of otitis media from a bacteriologic point of view is possible, if care is taken, but its value is questionable.

Ophthalmic Record, Chicago.

82 *Concerning the Terms Antimetropia and Anisometropia; Brachymetropia and Hypometropia in Place of Myopia; Hypermetropia and Hyperopia. G. F. Suker.

79. **Capsulotomy.**—Erwin advocates opening of the capsule and describes his method. After dilating the pupil he passes the cataract knife in the corneal margin at the equator. Then advancing on a plane declining 10 degrees from the horizontal he transfixes the capsule, then raises the point of the knife and counter punctures the cornea two or three mm. above the equator, and completes the corneal flap in its clear margin. Unless the capsule is especially brittle the knife will pass up under it to the pupillary margin, cutting a smooth central flap about the size of the ordinary pupil, which will be enlarged by the passage of the lens. This large flap will naturally fall to the lower segment of the capsule, leaving a clear pupil. This operation, he thinks, is so safe and complete and easily done he wonders why it has not been generally adopted. His last one hundred cases thus operated on have not shown a single case of sepsis, iritis or luxation, and only 8 cases have required a secondary operation.

82. **The Correction of Ophthalmic Terms.**—Suker pleads for the more correct use of the terms antimetropia and anisometropia, the former meaning a different kind of refraction and the other an unequal amount or degree of the same kind of refraction in the two eyes, supplanting a less useful term at the present time. He also suggests the use of brachymetropia and hypometropia in place of myopia and of hyperopia as expressing the relative amount of sight of one eye in comparison with the other without any reference to its actual refraction—simply the greater acuity of vision—instead of confusing it with hypermetropia, as is too often the custom. He notices the various definitions of these words and shows the present confusion in their current use. He urges that the term myopia should be discarded, as in its basic sense it signifies merely blinking or winking.

83. **Tetanus.**—Thompson reports 3 cases, all cured by chloral and bromid treatment, and in 2 supplemented by carbolis acid injections according to the Bacelli method.

93. **Drugs and Their Adulteration.**—Wiley's article is a very interesting, but rather a long one, showing how drug adulteration is often done, its saving of expense and the amount of swindling of the public which is carried on in this way. He mentions especially the substitution of acetanilid, which is worth about 2 cents per ounce, for phenacetin, which is retailed for about $3.20, making a profit something like 160 times the original value; the use of wood alcohol in extracts, etc. He notices the results of state board examinations, and the practice of the courts in regard to the question. He thinks that good national and state laws properly formulated would not require numerous annoying persecutions because the reputable dealer would be likely to readily fall in with the law.

Texas Medical Journal, Austin.

99 *Experiments to Determine the Disinfecting Value of the Morris Formaldehyd Generator. Allen J. Smith.
100 Tenotomy as a Preliminary Procedure for the Reduction and Cure of Talipes; Report of Eight Cases. J. S. Wooten.
101 Suggestions on the Preparations of the Lying-In Chamber. W. B. McLaughlin.

99. **Formaldehyd Disinfection.**—Smith's article is an experimental one with the Morris formaldehyd generator. A large proportion is taken up with tabulated statements of experiments. The room used for disinfecting experiments was not large and its absolute closure not possible, but from his trials it would seem that 1,000 c.c. of alcohol thus used are sufficient to effectually destroy the organisms in three hours' time in a room containing 850 cubic feet of air space or when the gas is generated in the proportion of 1.6 per cent. by volume or above. It would probably be best if the charge could be so arranged as to give approximately 2 per cent. per volume in rooms having more apertures. Under the conditions used in these experiments the gas generator is efficient in the destruction of the *Streptococcus pyogenes*, the *Bacillus typhosus*, the *Bact. anthracis*, the *Mycob. diphtheriæ* in from three to six hours of exposure. Its efficacy was evidenced by its distinct destruction of the sporulating anthrax. There are, however, some organisms that are resistant, as shown by the type of the *Bacillus subtilis* producing contamination, but this is not remarkable as special forms of this organism have been found to resist streaming steam for sixteen hours.

107 Notes on Cases of Sarcoma of the Nose, with Presentation of Pathologic Specimens and Micrographs. J. Price-Brown.
108 A Case of Empyema of the Frontal Sinus with Complications. T. W. Moore.

102. **Bilateral Aural Hemorrhage.**—Goldstein reports a case at length which had been thoroughly studied by other physicians as well as himself. He excludes by the history the charge of malingering, though that diagnosis had been made by leading authorities. He considers it largely a hysterical condition. The source of bleeding he could never absolutely ascertain, though he located it as nearly as possible in the angle formed by the posterior wall of the auditory canal in the plane of the membrana tympani. While he has seen it appear all at once he was not able to locate the bleeding point. The case seemed to be cured by radical suggestive therapy. The patient was anesthetized, the auditory canal dried out and the entire head put in a plaster-of-paris bandage. The patient was kept in the recumbent position and watched for forty-eight hours. A stiff crinoline bandage was then applied for forty-eight hours and renewed daily for one week. At the end of that time the dressings were removed and the patient announced cured and there has been no recurrence. He thinks the case is without a parallel in otologic literature. He reproduces all the other cases of bilateral hemorrhage of the auditory canal that he has found in the literature.

103. **Hemorrhage into the Tympanum.**—Oppenheimer reports cases showing this phenomenon and illustrating the tolerance of the tympanic cavity to large amounts of blood. While trauma is perhaps the most frequent cause, it may follow other diseases, as in the cases reported by Hektoen, Kümmel and others. The symptoms are impairment of hearing and tinnitus. Vertigo is absent as a rule. There may also be a history of otitis media as in the so-called hemorrhagic otitis media described by McBride.

106. **Facial Neuralgia.**—Peyre-Porcher holds that the most frequent cause of severe facial neuralgia is localized inflammation in the nose, antrum or teeth. In the last 6 cases treated by him the chief and only cause of the trouble was found in these organs. In 2 of the cases which he reports there had been removal of the gasserian ganglion without effect, and the nasal conditions had been entirely overlooked.

115 Cesarean Section Versus Abortion or Miscarriage in Women with Deformed Pelves. M. H. Bishop.

109. **Typhoid Fever.**—McCormick reviews his 22 fatal cases and details his treatment in the successful ones. His plan is to keep the bowels open first with calomel and then with saline, licorice powder or other laxative, using also camphor as an arterial stimulant in some cases, with the local application of guaiacol for the reduction of temperature both by topical applications and hypodermically, and in some cases preceding it with a hypodermic injection of 1/100 gr. of nitroglycerin. For hemorrhage he objects to the use of opium and relies on strychnin to support the circulation with hypodermoclysis of saline solution. He prescribes an easily digestible diet of animal broths, buttermilk, etc., not relying on any one thing. A careful examination of the stools is the guide for the diet. For an intestinal antiseptic he employs acid sulphate of soda and gives his results, also detailing extensive experiments on guinea-pigs and *in vitro*. He employed this drug in 4 cases and concludes from his observations:

That the acid sulphate of soda is germicidal to typhoid bacilli in a solution of 1 to 300. 2. That it does not have a toxic effect when used hypodermically on guinea-pigs in a solution of 1 per cent. 3. That it increases leucocytosis and, in this way, helps nature to combat the disease. 4. That it neutralizes typhotoxin, and must, in a measure, lessen the delirium, fever, diarrhea and mental stupor, and modify various other symptoms attributed to this poison. 5. That it prevents, to a great degree, the congestion of Peyer's patches and the other lymph follicles of the intestines. 6. By so doing it prevents, to some extent, hemorrhage and perforation. 7. That it will resist the bacilli or toxin in any portion of the body. 8. That it will greatly lessen the complications of the disease. 9. That it is a prophylactic, as it can be taken by mouth in large quantities in an antiseptic strength, and as it will not be neutralized in the stomach, although the susceptible typhoid stomach is one of subacidity. 10. That this acid sulphate of soda will replace physiologically the deficient hydrochloric acid. 11. That it furnishes an abortive treatment, since if it lessens the intestinal involvement it would necessarily shorten the disease. 12. It may be used to purify contaminated drinking water by allowing the solution to stand from twelve to fifteen minutes before being taken.

110. **Climate in Phthisis.**—Bissey's article chiefly treats of the climate of New Mexican resorts, the advantages of which he points out.

111. **Silver Antiseptics.**—Coblentz describes the various new silver preparations which have been brought forward as obviating the disadvantages of silver nitrate. Argentamine, (ethylene diamine silver nitrate) is less irritating than silver nitrate, though it still has this bad quality to some extent. Tachiol (silver fluorid) and silberol (silver sulphocarbonate) are mentioned as drugs in regard to which the literature is as yet too scanty to afford an opinion. Ichthargan is said to have an astringent as well as an antiseptic action, being a combination of silver nitrate and ichthyol sulphonic acid. Citrate and lactate of silver, which have been used by Credé in surgical practice both in solution and as dusting powders, are discussed. Care should be used in their application as they discolor the clothing. Argonin is a combination of silver, casein and alkali and argonin-L contains twice the strength in silver. Albargin is a combination of gelatose with silver nitrate; largin, a combination of para-nucleo-proteid with silver, containing 11.1 per cent. of the latter, a gray powder soluble in water; nargol, a combination of nucleinic acid and silver; argentol (silver oxychinolin sulphonate); collargol (argentum soluble Credé, or argentum colloidale), protargol and argyrol or silver vitellin. Nearly all of these are unstable preparations and require to be protected from the light. Their principal use has been in gonorrhea and eye troubles. The conclusions which he reaches are that the organic silver preparations represent a real addition to modern material medica. All of them are less irritating than the nitrate of silver, and therefore much better tolerated by the patient. The fact that they are not precipitated by albumin and chlorids enables them to penetrate more deeply into the tissues, and therefore promotes their germicidal activity. The percentage of silver is of much less importance than the special combination in which the silver exists.

1. **Surgical Tuberculosis.**—Tubby's article is a plea for the country hospital rather than treatment in city hospitals, on the ground that the air of cities is not good for the patients. He has taken the statistics of four municipal hospitals in London and one country hospital which he has been able to obtain, and finds that out of 218 cases treated in city hospitals only 68, or 31.2 per cent., were cured, while 58.6 per cent. were relieved. Relief is no cure in tuberculosis, and half cures are worse than none. Taking the statistics of one country hospital which he has obtained it does not, he says, have a fair chance, as many of its patients were sent down from London hospitals after treatment had been tried and failed. The operative work has not been specially successful there, and the total number of operations was 3. The results, however, showed 14 cures and 24 relieved out of 42 cases, and, therefore, while the stay in the hospital was much longer than in the city hospitals the proportion of cures was very much greater. The advantages of the country hospitals are the smaller number hospitals the proportion of cures was very much greater. The rural hospital, he thinks, should be devoted to but the one object, being conducted on definite principles. No limit should be made as to age; cases once admitted should stay until they are cured or clearly proven to be incurable and separate establishments should be provided for the latter.

6. **Tuberculosis of the Spine.**—Clarke reviews the recent work on this subject and gives reports of cases, personal and otherwise. From the experience derived he concludes that when paraplegia develops rapidly and involves the sensory as well as the motor functions operative interference is necessary, but in other cases rest in bed with some form of extension should be tried; this failing, a skiagraphic examination should be made and the choice then lies between laminectomy and lateral drainage. Removal of the transverse process alone, when guided by a skiagraph, will be sufficient to open a large abscess. He advises against curetting out the abscess cavity, as the cord may be exposed behind it. When there is a sharp angular deformity in the spine the cord will not be in danger of being bruised during the introduction of the tube, but when the spine is nearly straight the tube should be introduced in a forward direction. The daily injection of a small quantity of carbolic lotion may be made through the tube. The transverse processes on both sides of the spine may be removed in order to obtain thorough drainage. Clarke considers Keeley's operation too dangerous in ordinary hands. Menard's costo-transversectomy involves the risk of injury to the pleura. If the removal of a transverse process does not reveal an abscess, laminectomy may be proceeded with, either immediately or after an interval, and the presence of a lateral opening will produce an easy outlet for further suppuration and probably prevent extension of tubercular infiltration around the spine. He objects to weight extension as confining the patient to bed too closely. If bedsores threaten, a water bed should be used. He thinks that the frame of iron gas-piping of Bradfrod's, on which canvas is stretched and on which the patient can be carried is better than weight extension. Plaster-of-paris corsets and poroplastic supports are hot and heavy, but for temporary use molded troughs of plaster-of-paris or felt are useful.

15. **Malaria in Algiers.**—Among the points mentioned by Gros in reviewing his experience are that intense heat seems to affect the mosquito as unfavorably as extreme cold or dry weather. This explains the variations in the number of mosquitoes in different years.

16. **Relations of Arthritism to Diabetes.**—Fiquet argues that the arthritic temperament predisposes to certain diseases, but is not an affection in itself, being merely insufficiency of intracellular oxidations. It manifests itself differently, according to the kind of oxidation which is defective. If oxidation of the carbohydrates is insufficient, then diabetes mellitus appears. The oxidases which normally aid in the combustion of sugar are defective or absent, but those which preside over the combustion of albumin and fats may be present in abnormal amounts to make up for their deficiency. If the defective oxidases are those which aid in combustion of fats, then obesity results, while if the missing oxidases are those which aid in combustion of albumin, then a variety of diabetes ensues for which he proposes the name "albuminoic diabetes." Treatment is similar to that for ordinary diabetes, only the albuminous substances and not the carbohydrates must be omitted from the dietary. Cases of this kind may be detected in the early stages and impending serious disease warded off by a

hydrocarbonate and vegetable diet, iron to favor oxidations, massage and hydrotherapy to promote cellular functions in general and the oxidations in particular, and rest in country surroundings. The diagnosis is based on examination of the urine. Determination of the "coefficient of oxidation," that is, the proportion of the ureic nitrogen to the total nitrogen, is important, but not enough alone for the diagnosis. This is established by determination of the alimentary substances which have escaped the action of the oxidases. The best technic for the purpose is by precipitation of these substances by phosphomolybdic acid, which is as valuable for these cases as Fehling's reaction for diabetes mellitus. He adds to 15 c.c. of urine 10 c.c. of fluid containing in 15 gm. of distilled water, 1 gm. of the acid in crystals, and 25 gm. of an 1.18 per cent. solution of hydrochloric acid. The precipitate can be weighed or merely measured in a graduated test tube.

17. **Foreign Bodies in Nerve Cells.**—Marinesco's article was reviewed on page 690. It is copiously illustrated here.

18. **Centrifugalization as Test of Milk.**—Fabre recommends the practice which has been long in use at his clinic to determine the nutritive value of breast milk. After the child has been nursing for two or three minutes 10 c.c. of the milk are drawn into a graduated tube and three drops of methylene blue are added, which does not stain the cream. It is centrifugalized for five minutes, and the amount of space occupied by the cream determines the nutritive value of the milk. He sometimes proceeds further to test the amount of albumin, lactose, etc. In pathologic conditions the information derived has proved of the greatest value for further care of the infant.

19. **Vagino-Perineal Approach to Recto-Vaginal Fistulas.**—Legueu gives cuts of the various steps of his method of obliterating a fistula in the upper part of the recto-vaginal septum. He detaches and incises the rear wall of the vagina up to and beyond the fistula. He then sutures the rectal wall, and later the vaginal wall separately. The site of the lesion is amply exposed, while the disadvantages of incising the perineum proper are avoided.

21 La tachycardie orthostatique. J. Thomayer.

20. **Neurofibro-Sarcomatosis.**—Raymond has observed 2 cases of this affection, both in young subjects with tuberculous parentage. The symptoms developed suddenly without apparent cause, suggesting a brain tumor with its principal localization at the base of the brain. In some cases on record spinal symptoms were also observed, but not in his patients, and yet the spinal cord was the seat of multiple tumors in the case that came to autopsy. The main tumor is usually in the cerebello-protuberantial angle, of fibroplastic nature and adherent to the meninges. The nodules in the peripheral nerves usually escape discovery. Treatment can be only palliative owing to the multiplicity of the nodules. He believes that the condition may be regarded as a mesodermic tumor, a primary lesion of the connective tissue of the nervous system. The elements of ectodermic origin are not involved in the process.

25. **Embolic Transportation of Bullets in Heart or Large Vessels.**—Schloffer reports 2 cases of this kind. In one a bullet entering the heart was swept into the subclavian artery. The symptoms were pains in the arm and ischemic paralysis of the right forearm. In the second case a bullet entered the upper third of the femoral artery and was carried into the posterior tibialis posticus. The bullets were removed by an operation in each case. He has found 10 similar cases in the literature in which the bullet entered the circulatory system and remained at the spot or was swept along a certain distance. Experimental research also has confirmed the possibility of such an occurrence. The patients all died in this series. He has collected 23 cases of bullet wounds of the heart, and only 6 survived more than two months. In all of these the right ventricle had been the seat of the lesion.

27. **Treatment of Fissure and Prolapse of Rectum.**—Czerny describes a case of prolapse treated by operative intervention through a parasacral incision exposing the rectum and taking a lengthwise tuck in it with a row of button sutures. The stitches did not pass into the mucosa and the tuck projected toward the lumen of the intestine. The rectal wall was sutured at the same time with several catgut stitches to the severed fibers of the ligaments. By these procedures the wall of the rectum was made smaller and stiffer and it was suspended, thus completely counteracting the tendency to prolapse. He treats fissure by excision in profound anesthesia, uniting afterward the tip of the wound in the mucosa with the opposite point of the wound in the skin, drawing it out for the purpose by a suture passed through the mucosa at the tip of the incision. The rest of the wound is united with two to four stitches. The fissure is thus radically extirpated and the defect left is lined with sound mucosa. He has found the operation a success in his 6 cases treated in this way.

30. **Surgical Experiences in Kidney Disease with Functional Diagnostic Measures.**—Kümmel reviews his extensive experience at the general hospital at Hamburg, which includes 205 cases, with 228 operations. He states that kidney stones were diagnosed by the Roentgen rays in 18 cases, and in 16 they were found at the operation and in 2 at the necropsy, thus confirming the radioscopy in every instance. He regards silk catheters for the ureters as a great improvement, as they can be boiled freely. He boils them in a saturated solution of ammonium sulphate and keeps them in a dry glass cylinder. The information to be derived from cryoscopy is reviewed. His record includes 95 nephrectomies, with a mortality of 16.8 per cent., and he proclaims that since the new functional diagnostic measures have been introduced it has been reduced to 6.4 per cent. The article fills nearly 200 pages and is profusely illustrated. His total mortality was 31, and 174 of the patients were cured. He removed the kidney in 30 out of 35 cases of tuberculosis of the organ, with nephrotomy in 5, and reports 28 recoveries in this group.

31. **Bio-Chemistry of Pregnancy.**—Opitz describes experiments with what he calls a "syncytiolytic serum" derived from rabbits, goats, a heifer and a horse, previously injected with tissue from human placentæ freed from blood. The results of the tests were negative in regard to Veit's assumption in regard to syncytiolysis, but, on the other hand, the serum displayed an antitoxic power against the assumed syncytiotoxins which Opitz assumes to be circulating in the blood in eclampsia and to bear a causal relation to it. As soon as the maternal blood penetrates into the trophoblast, cells from the periphery of the ovum drop off into the maternal blood and are swept into various organs. These deported cells perish sooner or later under the action of cytolysins formed in the blood, and the products of their disintegration have a toxic action as foreign bodies. A substance is then produced to neutralize these toxic substances, an anti-syncytio-toxin. This process can be copied in animals by injection of placental tissue, and their serum then acquires the properties of an anti-syncytiotoxin. Opitz has applied this new serum in the treatment of several cases of eclampsia in Olshausen's service, and the results have encouraged the preparation of the serum on a larger scale, and it will soon be put on the market. He does not give any details of the effects on eclamptic subjects further than that it proved absolutely harmless, reserving the particulars for a later communication.

32. **Alkalinity of Blood.**—Orlowsky examined 63 patients with various affections to study the alkalinity of the blood in different morbid conditions. He found that in health it ranged from 240 to 267 mg. NaOH in 100 c.c. of blood with the litmus test, and that in various diseases the alkalinity is proportional to the number of red corpuscles, declining when there are few reds and increasing with them. Artificially increasing the alkalinity of the blood by internal administration of an alkali or by a tepid alkaline enema, has only transient effect. The action of the latter is more pronounced than that of the former.

33. **Generalized Infection with Thrush.**—Heubner's patient was a child of sixteen months, brought to the clinic with symptoms of a diphtheroid affection, suggesting the presumptive diagnosis of generalized infection with thrush. It was confirmed by the postmortem findings. The child died in less than a month after the first symptoms had been noticed. Injection of animals reproduced the syndrome and the anatomic changes. In both the little patient and the animals there was the same period of incubation, the high septic fever, the extreme acceleration of pulse and severe dyspnea without lung findings, with retention of consciousness and the rapidly fatal course. The lungs were the only organs free from the overgrowth of the fungi. The invasion could be traced from the necrotic tonsils into the lymph capillaries and thence into the general circulation. Without close attention and study of the case it would have been erroneously diagnosed and labeled diphtheria.

34. **Radio-Therapy of Cutaneous Affections.**—Scholtz reports his experience with different combinations of salves, *x*-rays, the iron lamp and the curette in skin affections, lupus in particular. By varying the combination he found it possible to obtain excellent effects.

37. **Antitoxin Treatment of Tetanus.**—Behring affirms that the day, even the hour, the minute, when the antitoxin can be applied, is of the greatest moment. He urges that it should be accessible at all times, as only by this means can a correct judgment as to its efficacy be formulated. A blank circular is given now with each vial, which the physician is requested to fill out with the details of the case and return.

38. **Congenital Malignant Growths.**—Joseph publishes from Czerny's clinic a case of a mixed tumor removed with the left kidney from a weakly child sixteen months old. Several varieties of tissue were found in the tumor which had evidently developed from the Wolffian body, including pure sarcomatous granulations. The infant has grown since into a remarkably healthy child, with no indications of recurrence of the malignant neoplasm. It was peculiarly interesting from the fact that the tumor formed a movable thrombus in the renal vein. It was the size of a fist, and weighed 600 gm. He reports also a second case, an embryonal tumor in the abdominal wall, in malignant degeneration, removed from an infant five months old, with no recurrence to date. The mothers were healthy in both these cases. The fetus can thus become affected with malignant disease, although apparently protected from the causes to which we are inclined to ascribe its etiology, and it can develop without affecting the maternal organism.

40. **Mechanical Treatment of Blepharoptosis.**—Abelsdorff had a spring applied on the inner side of the glasses the patient was in the habit of wearing, starting from the nose-piece. When putting on the glasses the latter lifted the drooping eyelid on the spring and thus mechanically corrected the deformity. No trace of the spring can be seen in the cuts showing the glasses in place.

41. **Quantitative Determination of Sugar in Urine.**—Behrendt points out that the Fehling reaction is unreliable in case of the presence of organic combinations of iron in the urine. He has been seeking to remedy this and describes a technic which is simple and sufficiently accurate. He uses an alkaline solution of bismuth nitrate which differs from Nylander's reagent in that only one-tenth of the amount of the nitrate is used. He weighs out 32.747 gm. of the sediment after dissolving the nitrate in distilled water. Then 500 c.c. of double normal soda solution is poured over it and the precipitate dissolved in 50 gm. Seignette salt (potassium sodium tartrate), and distilled water added to make a liter. He adds 10 c.c. of this fluid to 10 c.c. of the urine in an Esbach tube, and heats in the water-bath for half an hour. It is then set aside for fifteen to twenty minutes. The amount of the precipitate (bismuth oxydul) is the index of the sugar, as 1 c.c. corresponds to 1.4 per cent. sugar.

47 *Ueber Spondylitis infectiosa. H. Quincke (Kell).
48 *Chronic Inflammation of Spine. R. H. Focken (Heidelberg).—Ueber chronische ankylosierende Entzündung der Wirbelsäule.

43. **Struma with Metastasis in Bones.**—De Graag found metastases in the lungs and in the tenth and eleventh thoracic vertebræ in case of an adeno-carcinoma in the thyroid gland. The metastases, however, under the microscope resembled more the structure of the original thyroid gland than the structure of the neoplasm.

44. **Lymphatics of Esophagus Region.**—Injection of the cadavers of children by Gerota's method showed that the lymphatics of this region originate in two separate sets, with no direct communication between them. The first set is arranged lengthwise in the lower layer of the mucosa, while the second is not so large nor so regular, and forms a network on the surface of the perimysium. The lymphatics communicate directly with those of the pharynx above and those of the stomach below, although the intervening vessels may run a long way in the submucous tissue or against the wall before reaching them. The close clustering of glands around the recurrent nerve explains the paralysis of this nerve frequently observed in cases of carcinoma of the esophagus. He noted it in 18 out of 236 cases, and in 13 it was unilateral. The glands may, therefore, be grouped as the near and the distant. The latter are represented by the deep, lower cervical glands, found in the angle formed by the subclavian and internal jugular veins.

45. **Tuberculosis of Hernial Sac.**—About 58 cases of this condition have been published and Lewisohn has observed 4 more.

The affection may occur with or without effusion and with or without nodules. The diagnosis is difficult in the absence of evident tuberculosis elsewhere, but is suggested by an existing tubercular peritonitis, reducible, fluid contents of the sac, large nodules on the floor of the sac and smaller nodules leading toward the inguinal canal. The hernia may increase rapidly in size or may become tender. Operative treatment is urgently indicated, with extensive resection of the sac. The prognosis after operation is good; in some cases it was followed by the healing of an existing tubercular peritonitis.

46. **Hyperalgesia with Bullet Wounds of Head.**—Wilms noticed transient zones of hyperalgesia in the neck and back of the head in 4 cases of bullet wounds of the head. The zones did not correspond to peripheral nerves but to the cervical segments, and may be explained by assuming injury of the sympathetic at the sinus cavernosus. In one case the bullet was found at this point, and in 2 others it might have lodged there temporarily.

47. **Spondylitis Infectiosa.**—Quincke has observed a case of spondylitis consecutive to typical pneumonia, another consecutive to a streptococcus pleuritis and one after typhoid. He thinks that the bone marrow of the spine is affected in case of infections the same as the spleen, but that the abundance of blood in these organs renders them more resistant generally than the marrow of the long bones. This assumption of the involvement of the spine in severe infectious diseases explains many hitherto puzzling symptoms during convalescence. It also renders urgent the protection of the spine against trauma and over-exertion at this time.

48. **Spondylitis Deformans.**—Focken does not believe that a close distinction can be drawn between the Bechterew and the Marie-Strümpell types of chronic spondylitis with a tendency to ankylosis. Both in etiology, symptoms and the pathologic anatomy there is close resemblance between them. He thinks it probable that the same injurious agent which affects the ligaments acts also on the nervous system.

49. **Treatment of Nervous Cutaneous Affections.**—Joseph calls attention to the diagnostic value of the secondary lesions that develop after scratching an itching affection. In scabies and prurigo an eczematous process develops secondarily to scratching, but in lichen, after scratching, nothing but a recrudescence or new eruption of the lichen nodules is seen. Consequently in dubious cases the discovery of an eczematous lesion decides against lichen. The absence of eczema is also notable in pruritus, although in certain cases of circumscribed pruritus a lichenification of the scratched patches may be noticed, to which the name simple chronic lichen has been given. These lesions do not heal like lichen planus with little if any tendency to recurrence, but recur again and again and always at the same spot or spreading from these points. In the treatment of pruritus he has found nothing so effective as bromocol, a combination of dibromin and tannin, which he was the first to introduce into dermatology. Time has confirmed its value, especially of the mixture with glycerin, zinc oxid and starch, which dries at once into a varnish, rendering further dressing unnecessary. He recommends this as a very valuable remedy for pruritus of various origins, also for strophulus infantum and urticaria due to autointoxication. Bromocol plaster has proved a particularly convenient method of applying the bromocol in certain nervous affections.

50. **Treatment of Osteomyelitis with Iodoform Filling.**—Damianos illustrates a number of specimens and cases to support his assertions that chronic osteomyelitis is essentially an affection of the spongiosa, which fact has been overlooked heretofore in treatment. In reality, the irregularly distributed foci of granulation are the principal cause of the development and persistence of chronic myelitis. The spongiosa should be removed far into sound tissue, and this has been rendered possible by Mosetig's filling. He exposes the bone with a semi-circular incision and turns back the flap of soft parts, which includes the periosteum. He then removes the tissues affected, far into sound tissue, and fills the cavity left with the iodoform mixture described in THE JOURNAL, xl, p. 1,544, ¶75. Damianos gives radiograms of a number of patients thus treated with complete success, the limb functioning perfectly, free from pain and any tendency to recurrence of the bone affection.

51. **Diseases and Accidents of Wood-Workers.**—Steiner's practice in Herzegovina and Bosnia brings him in contact with men working in saw-mills and lumber camps, and his article is a comprehensive study of the subject, especially from the standpoint of industrial insurance. He notes that the largest number of accidents occur on Monday, and that the proportion of accidents is very much higher when the hours of work are long than when they are short, fatigue evidently rendering the men less cautious.

52. **Nephritis in Early Stages of Syphilis.**—Syphilitic infection may induce acute nephritis in hitherto sound kidneys, but it yields speedily to mercurial treatment. The effect at first seems to be an aggravation, as the kidney casts off the cells that have been injured by the syphilitic process, but when these have been expelled, the nephritis will be seen to have been cured by the specific treatment.

53. **Appendicitis.**—Carl Beck gives 12 cuts of interesting specimens and cases from his experience in America, and says a good word for the term "appendicitis" as descriptive and apt. The condition is not a typhlitis nor a perityphlitis nor a paratyphlitis, and these terms should not be applied to it. The Germans should use either the word "appendicitis" or their home term "Wurmfortsatzentzündung," which is etymologically correct if not very melodious. He also describes his operative technic with which Americans are familiar.

62 Beitrag zur Thier-Skoliose (in animals). Ottendorf (Vulpius' Institute, Heidelberg.)

54. **Habitual Luxation of Patella.**—The luxation was of traumatic origin in 3 of the 4 cases in Bade's experience. The other was a young girl with abnormally lax joints. In all the cases of habitual luxation the patella is unusually movable and the musculature relaxed. Treatment should be essentially the wearing of a splint which allows only extension and flexion of the knee. Direct fixation of the patella is seldom necessary, and a knee-cap is usually superfluous. Operation should not be attempted unless the gait is interfered with to an extent that disturbs the working capacity and depresses the patient. If surgical intervention is decided on it should

be thorough, some osteoplastic operation combined with shortening the capsule or osteotomy as indicated.

55. **Mikulicz's Plastic Operation on the Foot.**—Wieting shows by radiograms and description of several cases the gratifying results obtained by this method of operating on deformed feet without mutilating them. It is astonishing, he adds, how quickly the circulation becomes re-established in the remodeled foot through the narrow bridge left. The dorsal flexors are the only muscles left, but they impart elasticity to the foot. He thinks that the principle of the operation should be extended to other interventions.

57. **Fracture of Neck of Femur in Young Subjects.**—Hoffa remarks that since the introduction of radiography we have learned that fracture of the neck of the femur occurs more frequently in young subjects than the profession had hitherto imagined. No cases in children had been observed in the 75 fractures of the neck treated at König's clinic, and only 3 in the second decade, as reported a few years ago, but since then Hoffa has found 78 cases on record and 10 have been observed in his practice. In 1899 Gerstle was able to collect 53 cases of traumatic detachment of the epiphysis. In the total of 84 cases of injury of this part of the femur in which the age was mentioned, 17 of the subjects were under 5; 18 between 6 to 12; 34 from 13 to 16, and 15 from 17 to 20. Hoffa gives the details of his own and of some of the other cases. The symptoms at first of fracture of the neck or detachment of the epiphysis are slight. There is sharp transient pain, but the subjects are usually able to walk notwithstanding the injury. They are not confined to their bed long and the disturbances from the trauma are not apparent until after an interval of weeks or months. Very few are correctly diagnosed from the start; the injury is treated as a mere contusion and later as a coxitis, or, after healing, as a coxa vara statica. The absence of muscular atrophy and of reflex muscle spasms speaks against coxitis and also the sudden onset, and radioscopy will locate the lesion. The prognosis to date has not been good as to function. The epiphysis is apt to lose its slant and heal in a more or less vertical position, which changes also the direction of the neck as it develops further. Immobilization should be applied with a plaster cast if the fracture is seen early, and even after due consolidation of the fragments the patients should not be allowed to use the limb freely for a year at least, but should wear an appliance to relieve the thigh of the weight of the body, with massage and exercises to strengthen the muscles. When seen late, if massage and gymnastics and a supporting apparatus do not relieve, an operation is necessary, either resection or subtrochanteric oblique osteotomy.

60. **Chronic Arthritis in Children.**—Spitzy describes in detail the clinical history of 17 cases and the results of treatment, with numerous illustrations. He found systematic massage extremely useful, even in some cases rebellious to all other measures, especially when combined with active hyperemia. Immobilization was necessary in most cases at first, but he warns against its too prolonged use. The pernicious form of nodular rheumatism has always proved intractable. Not a single case of recovery is on record, but if a bacteriologic etiology can be determined serum treatment may supply the needed weapon.

63. **Alcohol in Therapeutics.**—Mircoli has previously proclaimed that the blood serum of persons accustomed to the use of alcohol—but not to a pathologic extent—possessed the power of neutralizing the action of tuberculin. He is convinced that alcohol confers an increased resisting power in respect to tuberculous infection. Experiments on rabbits under the influence of alcohol showed that they displayed a much more vigorous local reaction to inoculation of tubercle bacilli than the controls, and frequently the local lesion healed without general infection. Other experiments with rabbits given a large amount of alcohol at once produced results exactly opposite to those induced by the same amount in fractional doses over a long period. He also found that rabbits under the influence of a large dose of alcohol required twice the usual amount of tetanus toxin to induce symptoms. One of the rabbits after a large dose of alcohol showed pronounced autohemolysis and hemoglobinemia, urobilinuria and hemoglobinuria, additional testimony in regard to the action of alcohol on the composition of the blood.

67. **Significance of Auto-Hemolysis from Alcohol.**—Mircoli further states that the serum from healthy men accustomed to drink two or three quarts of wine a day proved bactericidal *in vitro* for cultures of the typhoid bacillus. Other experiences have demonstrated that besides this direct bactericidal action, the alcohol also stimulates the organism to elaborate greater quantities of more powerful alexins, thus aiding in repelling bacterial invasion. He suggests that it may be dangerous to deprive patients of their daily modicum of alcohol in case of an infectious disease affecting a person accustomed to its use. The production of alexins under the influence of alcohol is transient and ceases on its suspension. He thinks that his research has confirmed the fact that alcohol confers antitoxic, bacteriolytic and bactericidal properties on the serum, and enhanced resisting powers on the tissues. This does not occur directly, but by the participation of the organism thus temporarily stimulated by the alcohol.

68. **"Paraganglina" in Atony of Stomach or Intestines.**—This name has been applied to an extract of the medullary substance of the suprarenal capsule of beef cattle. It is not affected by the gastric juice, and is well tolerated by the stomach, while it has a decidedly favorable action on the motor function of the digestive tract administered by the mouth or rectum. The relief and improvement were so prompt and so remarkable in many cases of gastrointestinal atony and general asthenia, that Baccarani believes the symptoms must have been primarily caused by insufficiency of the suprarenals. The extract does not seem to have any cumulative action, but has a tendency to raise the blood pressure, increase the frequency of the pulse, the amount of urine, and the elimination of nitrogen and phosphoric acid in the urine, while the nitrogen in the feces is diminished.

69. **Agglutination with Horse Serum.**—Normal horse serum has no agglutinating or antitoxic properties, Caffarena reiterates, but acquires them by the addition of minute amounts of antituberculosis serum. Serum from horses immunized against tuberculosis has marked agglutinating power, up to 1/400.

71. **Graphic Tracings of Kidney Function.**—Mircoli points out a source of error in the findings of the methylene blue functional test of the kidneys. This is the "bioscopic" power of the serum, which varies in different conditions. Certain toxins also have an effect on the color of the stain, and the liver may influence its elimination. The findings are also unreliable in incipient or well-compensated kidney lesions, as the sound part may substitute the defective part. He also doubts the reliability of the phloridzin test, as injection of phloridzin increases the proportion of sugar in the blood even after extirpation of the kidneys. In other tests phloridzin was artificially circulated through one kidney, but no sugar was de-

tected in the ureter on this side, while it existed in the other ureter. He refers to recent experiences which suggest that the variations in the freezing-point are not absolute indices of the morbid conditions as some believe. The freezing-point remained the same before and after an uremic crisis in a case of glomerular nephritis consecutive to scarlet fever. The findings are liable to be influenced by ingestion of water, by change of diet and by the capacity of the tissues for absorption and retention. He has been conducting research along different lines, and believes that valuable information may be obtained by studying the spontaneous urine at different periods during the twenty-four hours, recording the frequency of micturition and the quantity of the urine, with its specific gravity at various hours, showing the relations between the secretion of water and of the solid elements dissolved in it. By the two curves thus obtained an insight into the actual work done by the kidneys is afforded. It can be expressed by the formula: Work equals the specific gravity multiplied by the number of cubic centimeters to the hour. The two lines representing the elimination of water and of solid materials parallel each other in health, and diverge or cross in parenchymatous nephritis. In the interstitial there is more or less irregularity, but the tendency is more towards a parallel. These graphic tracings may reveal disease, still latent, that escapes other tests.

72. **Experimental Administration of Antituberculosis Serum by the Stomach Route.**—Figari reports experiences with desiccated specific serum administered to guinea-pigs and to one patient in the clinic. The results established beyond question, he thinks, that it is possible to obtain effective curative results with specific serum treatment by the mouth the same as by subcutaneous injection. The serum of the animals acquired marked agglutinating property, and in the patient it rose from 1/10 to 1/50. His results corroborate those obtained by Roncagliolo with tuberculosis antitoxin administered by the mouth in his clinic.

73. **Lime as a Hemostatic.**—Silvestri's tests on dogs confirm the fact that lime has a coagulating effect on the blood and may prove effective in arresting hemorrhage. He administered it by the mouth to a patient with a tendency to hemophilia and found that after taking fractional doses of calcium hypophosphite for seven days the blood which at first did not coagulate for twelve hours, clotted abundantly in less than nine. He took at first 7 and then 4 gm. a day.

77. **Puerperal Tuberculosis of the Endometrium.**—Cova describes the clinical history and postmortem findings of a case of tuberculous endometritis, the first symptoms of which appeared in the form of diarrhea during the pregnancy. It was evidently aggravated by the puerperium and proved rapidly fatal. He has observed a second case of tuberculous endometritis, which was likewise rapidly fatal after delivery. Veit and Franqué have also reported cases of accelerated progress of genital tuberculosis after childbirth. Davidson and Merletti have published instances of miliary tuberculosis in the puerperium. Cova thinks that there are no mechanical reasons which can explain this increased gravity of tuberculous lesions in the peritoneal or genital regions such as explain the acceleration of tuberculous lesions in the lungs by the process of pregnancy and parturition. He suggests as a possible explanation for the extraordinary malignancy of tuberculous infection during the puerperium that the tubercle bacilli may find in the pregnant woman a particularly favorable soil for their development. Roster mentioned in the discussion that followed, a case of puerperal tuberculous infection of the peritoneum which took the form of periuterine exudates, followed by symptoms of pulmonary tuberculosis, although the patient survived for some time.

74 and 83. **Action of Veratrum Viride in Health and in Eclampsia.**—Chidichimo's researches on dogs and other laboratory animals indicate that veratrum viride has a marked depressant action in physiologic conditions. It rapidly reduced the temperature, and this reduction continued for hours, while about thirty hours were required before the drug was eliminated from the organism in case of rabbits and dogs. The facts observed indicate also that it acts mainly as a toxin on the muscles. On the whole his experience would impel him to proclaim that veratrum viride should be banished from the treatment of puerperal eclampsia if it were not for the possibility that the organism in the stress of eclampsia may react differently to the drug than might be expected from its physiologic action on animals. Pinzani reports in No. 1 three cases of puerperal eclampsia treated with this drug. He made 2 subcutaneous injections of 1 c.c. of the Italian fluid extract of veratrum viride, with a half-hour interval, after forceps extraction of a dead fetus. The same amount was given in a single dose to the second patient. The fetus was extracted later with forceps, as it was seen to be succumbing. The same amount was injected in the third case, but with a longer interval. Improvement was marked in all after the injections, as also in 6 other cases treated in the same way and previously reported. The women all recovered but the fetus did not survive. In one case he gave it by the mouth. The total amounts ranged from 1 to 4 c.c., never more than 3 c.c. in one dose. Saline infusion or enemata were the only other measures used. The pulse is the guide; as this becomes less rapid, under the influence of the veratrum, the convulsions subside.

84. **Cyclic Psychoses and Mania.**—This communication and the previous one in No. 19, treating of mania, both issue from the Moscow clinic for mental diseases. The writers urge the importance of distinguishing between a cyclic course in mania, melancholia and amentia and the true cyclic psychoses. The former may terminate in recovery, and this has led to the belief that the true cyclic psychosis is curable. They observed 86 cases of the latter, including 34 men. It formed 1.94 per cent. of all the mental diseases, but men afforded only one-third of the contingent. In two-thirds of all the cases the affection commenced between 16 and 25, as was also noted with mania, and it was usually ushered in with a phase of depression. Hereditary influences were noted in 87.5 per cent. of all the cases of mania, which numbered .56 of 2,840 male patients and 1.51 per cent. of 1,594 women. Heredity was also a factor in the cyclic psychoses in nearly the same proportion. Melancholia was much more common, especially in women, in whom it occurred seven times oftener than mania.

85. **Psychosis After a Burn.**—Toporkoff's patient recovering from childbirth developed an acute amentia with hallucinations after a burn of the third degree. As the general health improved the mental affection vanished.

86. **Displacement of Liver.**—Savelyeff describes in detail the clinical picture and methods of treating hepatoptosis.

88. **Actinomycosis of Lungs.**—Spisharny's 3 cases all terminated fatally, notwithstanding vigorous potassium iodid treatment and evacuation of the abscess in the wall of the thorax. The focal process deeper in the lung was not operated on as no communication could be found between it and the abscess. He is convinced that the focal process sometimes spreads by actual metastasis.

89. **Complications of Vincent's Angina.**—Ivanoff has observed 2 cases and reviews 9 on record to call attention to the complications liable to be encountered. There may be a polymorphous erythem and pains in the joints; occasionally, albuminuria, abscesses and even appendicitis have been observed. In his personal cases he discovered streptococci in the throat associated with Vincent's bacilli, and he ascribes the complications to their participation. He mentions that they are most liable to occur after stomatitis and glossitis.

90. **Surgery of Digestive Tract.**—Warnek's communication describes an extensive operation on the cecum, and in another case resection of part of the stomach, 9 by 15.5 cm., on account of a carcinomatous scirrhus at the pylorus. Both patients were in good health at time of writing, several months later.

91. **Leukemic Retinitis.**—Orloff gives cuts of his histologic findings to sustain his assertion that the tumor-like formations observed in the retina in the course of leukemia are merely accumulations of leucocytes at points where the walls of blood vessels have been destroyed. They occur only along the route of the vessels.

92. **Symptomatology of Multiple Sclerosis.**—Tutyshkin describes a case which he was able to diagnose correctly before the classical symptoms of nystagmus, tremor or disturbance in speech had developed. The progress of the affection confirmed his dictum. He based his diagnosis on the absence of the abdominal and cremaster reflexes and the discovery of the Babinsky sign on the right side only. The paralytic and spastic symptoms were also most pronounced on the right side. Among the early symptoms were periodical attacks of vertigo lasting several days, but then completely subsiding. He also noticed briefly transient attacks suggesting apoplexy: congestion with transient disturbance in speech and weakness in the right hand.

101 The Dark Side of Sterilization of Milk. N. P. Danilow.—Otritzatelniya storony sterilizatzie moloka v dyelye iskustvennago vskarmlivaniya dyetei.

93. **Resection of Nerves in Ablation of Tumors in Neck.**—Fedorow had occasion to resect the nerves in the neck in 4 cases of sarcoma which had grown around the nerves. He describes the cases in detail, the results showing that no disturbances followed resection of the spinal accessory nor of the nerves of the cervical plexus and short branches of the brachial plexus. Complete anesthesia of the skin of the side of the neck followed after the roots of the cervical plexus had been severed. His experience demonstrates that even extensive tumors in the neck can be successfully operated on, but those requiring resection of the vagus are most dangerous, especially when the common carotid and the jugular vein have to be resected also. Severe secondary symptoms may also follow resection of the long nerves of the brachial plexus, but, on the whole, his results are encouraging. All his patients recovered.

94. **Embolism of Aorta in Typhoid.**—Orlowski states that thrombosis of the abdominal aorta in the course of an infectious fever has been reported only 36 times, and he was able to find only 2 that corresponded to the case he describes. The patient was a young man, and on the fifteenth day symptoms developed suggesting myocarditis. The necropsy showed that thrombosis evidently followed, in the left ventricle, with embolism in the descending aorta.

96. **Repeated Cesarean Section.**—Orloff emphasizes that when a second operation of this kind is found to be necessary the prognosis is much better than for the first. The conditions are known and the patient is more tranquil. He describes a case in which a woman was thus delivered of a healthy child twice, with an interval of fifteen years. In operating, the probability of encountering adhesions must be borne in mind and the incision not made in the same place as the first. A "fundal" incision may prove advisable for these cases.

97. **Endogenic Origin of Eye Affections.**—Zelenkovsky publishes an account of experimental studies which indicate that the eye is liable to participate when there is infection elsewhere. The effects reach the eyes through the circulation and the anterior chamber is most liable to be affected. The posterior segment of the eye affords better conditions for microbes and consequently when they gain access to this part of the eye the resulting affection is more serious. Irritation of any kind and traumatism facilitate the entrance and lodgement of germs in the eye. On the other hand, he asserts that endogenic infection is not a factor in sympathetic ophthalmia.

98. **Action of Adrenalin on Animal Organism.**—Byelaventz has been experimenting with adrenalin on animals and noted that the rise in the blood pressure was due partly to spastic contraction of the vessels from stimulation of their walls and partly to stimulation of the heart action. It has at first a stimulating and then a paralyzing action on the centers of the vagus. When the pulse becomes accelerated the drug should be suspended. In small doses it promotes the gaseous interchanges, but in larger doses reduces them and with them the temperature. Death in intoxication from adrenalin is due to paralysis of the respiration center. The functional activity of the central nervous system is diminished by the drug. In conclusion he warns that he found it inconstant in its action and consequently urges great caution in administering it by the intravenous or subcutaneous routes.

99. **Differentiation and Treatment of Aneurism of Abdominal Aorta.**—Gurevitch remarks that the aneurism is almost invariably to be found on a level with the superior mesenteric artery. He has found that better results followed hygienic-dietetic measures than others. Subcutaneous injection of gelatin and internal administration of sodium iodid did not display much efficacy in his experience. The iodid is useful, however, when syphilis may be assumed. He reports three cases.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE AMERICAN ILLUSTRATED MEDICAL DICTIONARY. For Practitioners and Students. A Complete Dictionary of the Terms Used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry and the Kindred Branches, Including Much Collateral Information of an Encyclopedic Character, Together with New and Elaborate Tables of Arteries, Muscles, Nerves, Veins, etc.; of Bacilli, Bacteria, Micrococci, Streptococci; Eponymic Tables of Diseases, Operations, Signs and Symptoms, Stains, Tests, Methods of Treatment, etc., etc. By W. A. Newman Dorland, A.M., M.D., Editor of the "American Pocket Medical Dictionary." Flexible Leather. Pp. 798. Price, $4.50 net; with Thumb Index, $5.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

PROGRESSIVE MEDICINE. A Quarterly Digest of Advances, Discoveries and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia. Assisted by H. R. M. Landis, M.D., Assistant Physician to the Out-patient Medical Department of the Jefferson Medical College Hospital. Volume III. September, 1903. Diseases of the Thorax and Its Viscera, Including the Heart, Lungs and Blood Vessels; Dermatology and Syphilis; Diseases of the Nervous System;

Obstetrics. Cloth. Pp. 398. Price, $2.50. Philadelphia and New York: Lea Brothers & Co. 1903.

AMERICAN TEXT-BOOK OF SURGERY. For Practitioners and Students. Edited by William W. Keen, M.D., LL.D., F.R.C.S. (Hon.), Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, Philadelphia; and J. William White, M.D., John Rhea Barton Professor of Surgery, University of Pennsylvania, Philadelphia. Fourth Edition, Thoroughly Revised and Greatly Enlarged. Handsome Octavo of 1363 Pages, with 551 Text Illustrations and 39 Full-page Plates, Many in Colors. Cloth. Pp. 1363. Price, $7.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

AMERICAN POCKET MEDICAL DICTIONARY. Edited by W. A. Newman Dorland, A.M., M.D., Assistant Obstetrician to the Hospital of the University of Pennsylvania. Containing the Pronunciation and Definition of all the Principal Terms Used in Medicine and Kindred Sciences, Along with Over 60 Extensive Tables. Fourth Edition, Revised and Enlarged. Flexible Leather. Pp. 566. Price, $1.00. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

A TEXT-BOOK OF OPERATIVE SURGERY. Covering the Surgical Anatomy and Operative Technic Involved In the Operations of General Surgery. Written for Students and Practitioners. By Warren Stone Bickham, Phar.M., M.D., Assistant Instructor in Operative Surgery, College of Physicians and Surgeons, New York. With 559 Illustrations, Entirely Original. Cloth. Pp. 984. Price, $6.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

CLINICAL EXAMINATION OF THE URINE AND URINARY DIAGNOSIS. A Clinical Guide for the Use of Practitioners and Students of Medicine and Surgery. By J. Bergen Ogden, M.D., Formerly Instructor in Chemistry, Harvard University Medical School, Boston. Second Revised Edition. Illustrated, Including 11 Plates; 9 of Them in Colors. Cloth. Pp. 418. Price, $3.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

NERVOUS AND MENTAL DISEASES. By Archibald Church, M.D., Professor of Nervous and Mental Diseases and Head of Neurological Department, Northwestern University Medical School; and Frederick Peterson, M.D., President New York State Commissioner in Lunacy. Fourth Edition, Thoroughly Revised and Enlarged. With 338 Illustrations. Cloth. Pp. 922. Price, $5.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

LESSONS IN DISINFECTION AND STERILIZATION. An Elementary Course of Bacteriology, Together with a Scheme of Practical Experiments Illustrating the Subject-matter. By F. W. Andrewes, M.A., M.D. Oxon., F.R.C.P. Lond., D.P.H. Cantab., Lecturer on Pathology, Pathologist and Sanitary Officer to St. Bartholomew's Hospital, London. Cloth. Pp. 222. Price, $1.05. London: J. & A. Churchill. Philadelphia: P. Blakiston's Son & Co. 1903.

A COMPEND OF HUMAN ANATOMY. By Samuel O. L. Potter, M.A., M.D., M.R.C.P. Lond., Formerly Professor of the Principles and Practice of Medicine in the Cooper Medical College of San Francisco. Seventh Edition, Revised and Enlarged. With 138 Wood Engravings; also Numerous Tables and 16 Plates of the Arteries and Nerves. Cloth. Pp. 372. Price, 80 cents net. Philadelphia: P. Blakiston's Son & Co. 1903.

CHEMISTRY, INORGANIC AND ORGANIC, WITH EXPERIMENTS. By Charles Loudon Bloxam. Ninth Edition, Rewritten and Revised. By John Millar Thomson, LL.D., F.R.S., Professor of Chemistry, King's College, London; and Arthur G. Bloxam, F.I.C., Consulting Chemist and Chartered Patent Agent. Cloth. Pp. 871. Price, $6.00 net. Philadelphia: P. Blakiston's Son & Co. 1903.

A TEXT-BOOK OF THE PRACTICE OF MEDICINE. By James M. Anders, M.D., Ph.D., LL.D., Professor of the Practice of Medicine and of Clinical Medicine, Medico-Chirurgical College, Philadelphia. Sixth Edition, Thoroughly Revised. Fully Illustrated. Cloth. Pp. 1,300. Price, $5.50 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

A TEXT-BOOK UPON THE PATHOGENIC BACTERIA. For Students of Medicine and Physicians. By Joseph McFarland, M.D., Professor of Pathology and Bacteriology in the Medico-Chirurgical College, Philadelphia. Fully Illustrated; a Number in Colors. Cloth. Pp. 629. Price, $3.50 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

A TEXT-BOOK OF OBSTETRICS. By J. Clarence Webster, M.D. Edin., F.R.C.P.E., F.R.S.E., Professor of Obstetrics and Gynecology, Rush Medical College, in Affiliation with the University of Chicago. With 383 Illustrations; 23 in Colors. Cloth. Pp. 761. Price, $5.00. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

A HANDBOOK OF THE DISEASES OF THE EYE AND THEIR TREATMENT. By Henry R. Swanzy, A.M., M.B., F.R.C.S.I., Surgeon to the Royal Victoria Eye and Ear Hospital. Eighth Edition. With 168 Illustrations and Zephyr Card of Holmgren's Tests. Cloth. Pp. 580. Price, $2.50 net. Philadelphia: P. Blakiston's Son & Co. 1903.

A COMPEND OF THE DISEASES OF THE SKIN. By Jay F. Schamberg, A.B., M.D., Professor of Diseases of the Skin, Philadelphia Polyclinic and College for Graduates in Medicine. Third Edition, Revised and Enlarged. With 100 Illustrations. Cloth. Pp. 291. Price, 80 cents net. Philadelphia: P. Blakiston's Son & Co. 1903.

A TEXT-BOOK OF PATHOLOGY. By Alfred Stengel, M.D., Professor of Clinical Medicine in the University of Pennsylvania. With 394 Text Illustrations, many in Colors, and 7 Full-page Colored Plates. Cloth. Pp. 933. Price, $5.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

SERUM THERAPY, BACTERIAL THERAPEUTICS AND VACCINES. R. T. Hewlett, M.D., M.R.C.P., D.P.H. Lond., Professor of General Pathology and Bacteriology, King's College, London. Cloth. Pp. 262. Price, $1.75 net. Philadelphia: P. Blakiston's Son & Co. 1903.

A TEXT-BOOK OF OBSTETRICS. By Barton Cooke Hirst, M.D., Professor of Obstetrics in the University of Pennsylvania. With 746 Illustrations; 39 of Them in Colors. Cloth. Pp. 900. Price, $5.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

A TEXT-BOOK OF DISEASES OF WOMEN. By Thomas A. Ashby, M.D., Professor of Diseases of Women in the University of Maryland. With 233 Illustrations. Cloth. Pp. 661. Price, $4.50. Baltimore: Williams & Wilkins Co. 1903.

HOMOPHONIC CONVERSATIONS IN ENGLISH, GERMAN, FRENCH AND ITALIAN, Being a Natural Aid to the Memory in Learning Those Languages. By. C. B. and C. V. Waite. Cloth. Pp. 137. Price, $1.00. Chicago: C. V. Waite & Co.

TRANSACTIONS OF THE WEST VIRGINIA STATE MEDICAL ASSOCIATION. Charleston, May 26, 27 and 28, 1903. Instituted April 10, 1867. Paper. Pp. 144. Wheeling: West Virginia Printing Company. 1903.

ANNUAL REPORT OF THE ESSEX COUNTY HOSPITALS FOR THE INSANE. Newark, N. J. For the Year Ending April 30, 1903. Paper. Pp. 81. Newark, N. J.: Groebe-McGovern Company. 1903.

TRANSACTIONS OF THE AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS. Vol. XV. For the Year 1902. Cloth. Pp. 381. New York: Press of Stettiner Bros. 1903.

TRANSACTIONS OF THE IOWA STATE MEDICAL SOCIETY. Volume XXI. Fifty-second Annual Session, 1903. Cloth. Pp. 472. Council Bluffs, Iowa: New Nonpareil Company. 1903.

UNIVERSITY OF PENNSYLVANIA. Contributions from the William Pepper Laboratory of Clinical Medicine (Reprints). No. III. Paper. Philadelphia. 1903.

The Public Service.

Navy Changes.

Changes in the Medical Corps of the U. S. Navy for the week ending Sept. 5, 1903:

Asst.-Surgeon R. A. Bachmann, detached from the naval station, Cavite, P. I., and ordered to naval station, Guam, L. I.

Surgeon M. F. Gates, detached from the *Atlanta* and ordered to the Naval Hospital, Philadelphia, September 21.

Surgeon W. B. Grove, detached from the Naval Hospital, Philadelphia, and ordered to the *Atlanta*.

Asst.-Surgeon J. A. Murphy, detached from the *Celtic* and ordered home to wait orders.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Sept. 12, 1903:

SMALLPOX—UNITED STATES.

California: Los Angeles, Aug. 22-29, 2 cases.
Illinois: Chicago, Aug. 30-Sept. 5, 2 cases.
Massachusetts: Fall River, Aug. 30-Sept. 5, 6 cases.
Ohio: Cincinnati, Aug. 29-Sept. 4, 2 cases; Dayton, Aug. 30-Sept. 5, 1 case; Toledo, Aug. 30-Sept. 5, 1 case.
Pennsylvania: Pittsburg, Aug. 8-15, 46 cases, 15 deaths.
South Carolina: Charleston, Aug. 30-Sept. 5, 1 case.

SMALLPOX—FOREIGN.

Belgium: Antwerp, Aug. 8-22, 3 deaths.
Brazil: Rio de Janeiro, July 26-Aug. 9, 22 deaths.
British Guiana: Demerara, July 4-18, 3 deaths.
Canada: Vancouver, Aug. 1-31, 1 case.
Colombia: Barranquilla, Aug. 16-23, 3 deaths; Bocas del Toro, Aug. 18-25, 1 case.
Great Britain: Dundee, Aug. 15-22, 1 case; Leeds, Aug. 8-29, 24 cases; Liverpool, Aug. 15-22, 10 cases; London, Aug. 15-22, 13 cases; Newcastle-on-Tyne, Aug. 15-22, 5 cases, 1 death; South Shields, Aug. 15-22, 2 cases; West Hartlepool, Aug. 15-22, 1 case.
India: Bombay, Aug. 4-11, 8 deaths; Calcutta, Aug. 1-8, 1 death.
Italy: Catania, Aug. 20-27, 1 death.
Mexico: Vera Cruz, Aug. 22-29, 2 cases.
Russia: Moscow, Aug. 8-15, 1 death; Odessa, Aug. 15-22, 3 cases; St. Petersburg, Aug. 8-15, 3 cases.
Straits Settlements: Singapore, July 11-18, 1 death.
Turkey: Constantinople, Aug. 16-23, 1 death; Smyrna, July 19-Aug. 9, 60 deaths.
Venezuela: Maturin, Aug. 17, present.

YELLOW FEVER.

Brazil: Rio de Janeiro, July 25-Aug. 9, 5 deaths.
Colombia: Bocas del Toro, Aug. 24-31, 2 cases, 1 death.
Costa Rica: Limon, Aug. 20-27, 2 cases, 1 death.
Mexico: Citas, Aug. 23-30, 45 cases, 7 deaths; Coatzacoalcos, Aug. 22-29, 1 case, 1 death; Merida, Aug. 16-29, 21 deaths; Progreso, Aug. 16-22, 2 cases, 1 death; Tampico, Aug. 16-29, 30 cases, 26 deaths; Tehuantepec, Aug. 16-29, 8 deaths; Salina Cruz, Aug. 16-29, 10 cases, 6 deaths; Vera Cruz, Aug. 22-29, 61 cases, 15 deaths.

CHOLERA—FOREIGN.

China: Amoy, July 18-Aug. 1, 650 deaths.
India: Bombay, Aug. 4-11, 3 deaths; Calcutta, Aug. 1-8, 9 cases.
Peru: Pacasmayo, Aug. 13, present.
Straits Settlements: Singapore, July 4-11, 15 deaths.

PLAGUE—INSULAR.

Philippine Islands: Cebu, Sept. 3, present.

PLAGUE—FOREIGN.

Bolivia: La Paz, Aug. 13, present.
Brazil: Rio de Janeiro, July 25-Aug. 9, 8 deaths.
China: Amoy, July 18-Aug. 1, 100 deaths; Hongkong, July 18-25, 13 cases, 11 deaths.
India: Bombay, Aug. 4-11, 56 deaths; Calcutta, Aug. 1-8, 9 deaths.
Peru: Arequipa, Aug. 13, present; Molendo, Aug. 13, present.

THE BACTERIA CONCERNED IN THE PRODUCTION OF EYE INFLAMMATIONS.*

ROBERT L. RANDOLPH, M.D.

BALTIMORE.

I do not think we are called on to discuss the so-called eye bacteria from a historical point of view, for that would mean a consideration of nearly all these bacteria in their causal relationship to the diseases with which they were first identified. As a matter of fact, we have not found any bacteria which are pathogenic only for the eye, though the possibility of there being such bacteria is suggested when we think of sympathetic ophthalmia and trachoma, two diseases which appear to be peculiar to the human race, and one of which, in all probability, is due to a specific bacterium.

Before speaking of the bacteria which we usually regard as pathogenic for the human eye, I may be pardoned for introducing matter which to many of you may seem very elementary, but which may help to a better understanding of what follows. Bacteria may be divided into two classes, the saprophytes, or those which obtain their nutrition from dead organic material, and the parasites, or those which live at the expense of some other living organic creature. The activities of the saprophytes lead to decomposition, putrefaction and fermentation, while the activities of the parasites result in disease and death. The saprophytes resolve dead animal and vegetable bodies into simpler compounds, carbonic acid, water and ammonia, which serve as food for vegetation, and for this reason this group of bacteria may be regarded as benefactors, while the parasites exist at the expense of some living organic creature, or to put it stronger, at the expense of sight and life. It is to the second class, the parasites, that the group of eye bacteria belongs. In this group we will find two of the grand divisions of bacteria in general micrococci or cocci and bacilli, these names being given them according to their individual outline, the cocci being round or sphere-shaped, the bacilli being rod-shaped. The third grand division of bacteria, the spirilla, finds no representatives in the group of so-called eye bacteria.

In the group of micrococci we find the *Streptococcus pyogenes,* the *Staphylococcus aureus* and *albus,* the pneumococcus and gonococcus. In the group bacilli, we have Weeks' bacillus, the diplobacillus of Morax-Axenfeld, the diptheria bacillus, xerosis bacillus, tubercle bacillus, *Bacillus pyocyaneus* and colon bacillus. Several of these bacteria are often found in the normal conjunctival sac, and the *Micrococcus epidermidis albus* may be regarded as an almost constant inhabitant of this location, and to a somewhat less extent this is the case with the xerosis bacillus. These two bacteria, then, can not be regarded as actually pathogenic for the human conjunctiva, but I have included them in the group of eye bacteria because they are so closely associated with the life history of the eye, and as I have observed elsewhere, both these organisms under certain conditions can become pathogenic and cause inflammation. Very recently I have had occasion to make repeated cultures from the conjunctival sac of an individual with intense monocular conjunctivitis, which, clinically speaking, was indistinguishable from "pink eye," and I was never able to get anything in either culture or cover-slip but the xerosis bacillus. What rendered this micro-organism pathogenic in this particular case I am unable to say. More than once I have been forced to the conclusion that the *Micrococcus epidermidis albus,* which I have found so often in the normal conjunctival sac, was apparently the cause of an intense conjunctivitis which I was treating. The colon bacillus is another organism which is not generally considered pathogenic, but there is sufficient evidence to warrant the belief that it does become very pathogenic under certain circumstances, so that its presence in diseased conditions while possibly accidental, not infrequently means its direct causal relationship to the disease. A number of cases of catarrhal conjunctivitis have been reported where the colon bacillus was found in the conjunctiva in pure culture, and several years ago I reported a case of panophthalmitis in which I obtained this organism from the vitreous in pure culture. These three organisms, then, are the least pathogenic of the group. When we pass to the other members of this family or group the element of pathogenicity comes out stronger, being most marked in the diphtheria bacillus, then in the gonococcus, Weeks' bacillus, pneumococcus, diplobacillus of Morax-Axenfeld, tubercle bacillus, streptococcus and *Staphylococcus aureus.* The latter organism, as it is found so frequently associated with a normal condition of the conjunctiva and lids, may almost be classed with the three organisms which I have indicated as being relatively less pathogenic. The streptococcus is another organism which is most inconstant in its effects. At times it will seem to have little, if any, virulence, no matter how tested, while again, it exhibits very marked pathogenic properties. When found as the active factor in an ophthalmia we usually have a very intense reaction, as seen in the streptococcus diphtheria of the conjunctiva, also in Parinaud's conjunctivitis. Of course, my grading these bacteria as regards their pathogenic value is an

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, being Part I (accompanied with lantern slide demonstration) of a symposium on the Bacteriology of the Eye by a committee consisting of Robert L. Randolph (chairman), Brown Pusey and Edgar Thomson. Approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks.

entirely arbitrary arrangement, but judging from the effects produced by their toxins, the arrangement seems to me a reasonable one. All these organisms, however, irrespective of their pathogenicity, require to some extent a helping hand to render them capable of doing harm. While it is impossible to demonstrate always the exact nature of this co-operative agency, it is almost certain in a great number of cases that it consists in an abrasion or injury of the epithelium. Whatever lowers local resistance favors the multiplication of any bacteria which might happen to be in the conjunctival sac, and in overwhelming numbers ordinarily harmless bacteria can become dangerous. The more pathogenic an organism the greater would be the odds against the eye in case of mechanical injury, and I am convinced that the freedom of the eye from suppuration after penetrating wounds from accidents as well as from operations, while due in larger measure to the natural resistance of the eye to the disease, is also to no little extent due to the feeble pathogenic properties of those bacteria which are so often found in the conjunctival sac. No matter how pathogenic the bacteria if they fail to multiply it means that the battle is not to them. The sooner we realize, in dealing with the normal conjunctiva, that the latter is adequately equipped for adversity, the better will be the results of our operative work, and I look forward to no distant day when antiseptic irrigations of the normal conjunctiva in cataract operations will have been generally abandoned, and I am sure that during the past few years there has been a steady growth in the realization of the principle, clean hands, clean instruments, clean cocain, and leave the rest to the tissues of the eye. These rather practical thoughts suggest themselves to me in speaking of the bacteria which are found in the normal conjunctiva. Sometimes I am almost tempted to think that the bacteria which are so often found in this location perform certain important functions in the life of the normal conjunctiva, and that it is not intended we should disturb this relationship. We know that efforts to bring about intestinal and vaginal antisepsis have been followed by worse than failure, and that in the case of one enterprising obstetrician a large crop of puerperal fevers resulted. It is the same story here, bacteria ordinarily harmless are rendered harmful because our mental attitude toward bacteria in general is hostile, but I am convinced that with increasing knowledge we will be compelled to take up another position, even perhaps to regard some of the bacteria which are found in our bodies as benefactors, as blessings in disguise.

BACTERIA IN THE EYE,

AND NOTES ON SOME RECENT WORK IN OPHTHALMOLOGIC BACTERIOLOGY.*

BROWN PUSEY, M.D.
Instructor in Pathology of the Eye in the University of Chicago; Assistant in Ophthalmology in Rush Medical College.
CHICAGO.

Such an appropriate opening of a subject as that which is forced on me is seldom given to a man. The natural manner in which to consider my subject is to begin with the bacteria that may infect the human conjunctiva, and of these the bacillus of acute, contagious conjunctivitis must first have attention. In the writings of a celebrated German ophthalmologist we find the sentence: "For the principal work in the investigation of this microörganism and the real demonstration of it as the cause of a particular form of conjunctivitis, we are indebted to him who in 1886 described the first cases, in which he was able to prove this microörganism to be the cause of this disease." I have the pleasure of showing a specimen containing the organisms spoken of in the above sentence, which bear the name of the investigator referred to—Weeks, the chairman of our Section. My quotation is from the writings of a gentleman who was to have been the guest of this Section—Professor Uhthoff.[1]

The specimen is a smear from a conjunctival discharge. This statement reminds me of the fact that in studying bacteria in the conjunctival tissue we are greatly handicapped, because many of the organisms that cause conjunctivitis in man do not lend themselves to experimentation in the conjunctivæ of animals. Such is the case with the bacillus of Weeks, the Morax-Axenfeld diplobacillus, the diphtheria bacillus and the gonococcus. It is a curious and interesting fact that the last-named organism has never been found as a parasite in other animals. These organisms will not grow in the conjunctiva of animals, and, as we can hardly excise human conjunctiva for the purpose of such a demonstration, I can not show them in tissue.

In passing, I may refer to the fact that Weeks[2] and Morax[3] have examined tissue containing the small bacillus, and of the severe forms of conjunctivitis Randolph[4] has obtained such tissue from rabbits by injecting diphtheria toxin.

Taking up the chronic forms of conjunctivitis, I am fortunate in the possession of a specimen of leprosy of the conjunctiva, stained to show the lepra bacilli.

Of the chronic forms of conjunctivitis, none is so important as trachoma, and it would be most appropriate if I could at this point show the microörganism of this disease. You will all join me in my regret that such a demonstration is still impossible.

Before leaving the subject of the conjunctiva, I wish to refer to the very important recent work of the chairman of our committee—Dr. Randolph.[4] He has investigated the rôle of the bacterial toxins in inflammations of the eye, and has demonstrated for the first time that, in general, these toxins are incapable of absorption from the intact conjunctival surface, hence such toxins instilled into the healthy conjunctival sac do not produce inflammation; but if they are injected into the conjunctiva or anterior chamber, they invariably set up local inflammation. His conclusions are most interesting, and his experiments, as he says, are in harmony with clinical experience, in that a lesion of continuity is shown to be important, not only in opening a path for invasion by bacteria, but in permitting the entrance of toxins, which constitute the weapons by which the bacterial cells do injury. In this important work Randolph records a study of the bacteriology of the normal conjunctiva of the rabbit, based on an examination of

* Read, with stereopticon illustration, at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks.

1. Uhthoff, W.: Ueber die neuren Fortschritte der Bakteriologie auf dem Gebiete der Conjunctivitis und der Keratitis des Menschen Sammlung zwangloser Abhandlungen aus dem Gebiete der Augenheilkunde, ii, 5, p. 17, 1898.

2. Weeks, J. E.: The Bacillus of Acute Conjunctival Catarrh or "Pink-eye," Knapp's Arch., xv, p. 441, 1886.

3. Morax, V.: Recherches bacteriologiques sur l'etiologie der Conjunctivites algues, etc., Thèse de Paris, 1894.

4. Randolph, R. L.: The Rôle of the Toxins in Inflammations of the Eye, Amer. Jour. Med. Sci., November, 1902; also, Bulletin Johns Hopkins Hosp., March-April, 1903.

forty-seven cases. The value of this latter will be appreciated when it is recalled that practically all the experimental work of the ophthalmologist is done on the rabbit's eye, and heretofore no work had been done on the bacteriology of the eye of this animal.

Passing from the conjunctiva to the eyelids, I would call attention to the work of Hala[5] in demonstrating microörganisms in chalazion. In this work he verifies the findings of Professor Deyl, and it is of such interest that I venture to quote from his conclusions:

"Chalazion is an infectious bacterial process. The bacilli in incipient chalazion are in all their characteristics identical with that group of bacteria which are designated as xerosis bacilli. The so-called xerosis bacilli which exist in the normal and particularly in the different pathologic conditions in the conjunctival sac, get into the conjunctival tissue by rubbing of the irritated eyes, and cause an acute inflammatory process, which terminates in a chronic swelling filled with granulation tissue. The different catarrhal conjunctival affections, and the asthenopias, are predisposing factors. Contrary to the view of Baumgarten concerning the absolute avirulence of the so-called *Bacillus xerosis,* we have the experimental production of the chalazion process in the eyelids of rabbits by these bacilli, which are derived not only from human chalazion, but also from other pathologic processes. The chalazion is not a retention cyst, and it presents no signs of and has no relation to tuberculosis."

The histologic findings in chalazion make one a little uncertain in accepting unhesitatingly the last statement. The findings of Hala increase our interest in the *Bacillus xerosis* and make the article of Denny,[6] on its morphology and the morphology of its kindred forms (*B. diphtheriæ* and *B. pseudodiphtheriæ*) of more importance to us.

While on the subject of the eyelids, I may call attention to a suggestive paper by Dr. P. Friedenberg.[7] Starting with the fact that the hair follicles, crypts and glands of the lid margin may, even in apparently healthy lids, retain sebaceous matter, fatty detritus and a varied flora of bacteria, he demonstrates the importance of expression of the lid margins as a therapeutic measure in blepharitis and its complications.

Further important, recent work is that of Römer,[8] Mayer[9] and Hiroto[10] on the subject of the conjunctival sac as a route of general infection. General infection, which has been produced in numerous animal experiments by the introduction of organisms, e. g., pneumococci, into the conjunctival sac, may well give rise to interesting speculation. Hiroto, agreeing with Römer, concludes that in cases of infection by this route, the bacteria enter the circulation not directly from the conjunctiva, but from the mucosa of the nose, to which they are carried by the tears.

Of the serious eye affections, corneal ulcer is in the first class. Of corneal ulcers none is worse than the serpent ulcer. It has been given to Professor Uhthoff[11] [12] and his colleague, Professor Axenfeld, to demonstrate that the serpent ulcer is due to infection with the pneumococcus. The great importance of this work will be appreciated when we think of the possibilities in the treatment of these awful ulcers with antipneumococcic serum.

The next slide shows pneumococci on the edge of the cornea; this section is from an eye enucleated because of an epithelioma, and evidently has been obtained in the beginning of the infection with the diplococcus. The next slide shows these organisms in an eye that went to pieces from a serpent ulcer, and the following section shows the tissue stained with hematoxylin-eosin, and some of the results of the action of the organisms. For the sections from the serpent ulcer, I wish to acknowledge my indebtedness to Dr. E. A. Shumway. We are familiar with the histologic findings in such an ulcer of the cornea, but I wish to emphasize the extension of these organisms in colonies between the corneal lamellæ and the character of the leucocytes in the anterior chamber — polymorphonuclear leucocytes. The next section, for which I am also indebted to Dr. Shumway, shows staphylococci in the cornea.

Hematoxylin usually is not a satisfactory stain for bacteria. This is due to the fact that in ordinary infected tissue there are many nuclei of fixed as well as mobile cells, that take this stain and interfere with the recognition of organisms. I would call attention to the fact that the scarcity of nuclei and the absence of blood vessels in the cornea and, consequently, the slower emigration of leucocytes, allow this stain to show bacteria unusually well in the corneal spaces.

The next section shows gonococci in the cornea. For this section I am indebted to Dr. Gertrude French[13] of Portland, Ore. She got the material from the private practice of Dr. Gruening of New York. For evident reasons, such material is very rare.

Before leaving the subject of ulcer of the cornea, I would allude to the fact that our branch of the science of medicine is abreast of the times in the field of serum therapy. The use of diphtheria antitoxin in diphtheritic conjunctivitis is ancient history, and I believe it is appropriate here to register the ophthalmologist's debt of gratitude to von Behring. Recent work in the subject of serum therapy applies to that miserable ulcer of the cornea—the serpent ulcer. This work has been done by Römer,[14] and in his last communication he reports results that give us reason to expect that by the use of this serum this ulcer will lose its terror.

While dealing with this region of the eye, I may direct attention to a recent and interesting suggestion of Mr. Collins[15] as to a reason why wounds of the ciliary region are especially apt to be followed by sympathetic ophthalmia. He calls attention to the facts, that perforation of the globe in the region of the choroid is not apt to be followed by prolapse—the uvea tends to retreat

from the sides of the wound; in wounds of the cornea, the iris may prolapse, but it is not left with a vascular membrane over it; while in the ciliary region, a wound is apt to result in a prolapse, and such a prolapse will be covered with a vascular membrane—the conjunctiva—which is very prone to inflammation. "The possibility of subconjunctival entanglements of the iris or ciliary body forming the track along which inflammation (bacteria), likely to excite sympathetic disease, may enter an eye any time after the receipt of an injury, may be one reason why wounds of the ciliary region are specially liable to be followed by this complication."

The next specimen, for which I am also indebted to Dr. Shumway, is one which shows streptococci in the lens. This resulted from a penetrating wound.

The next shows the tubercle bacillus in an eye with tubercular iridocyclitis, which Dr. Hotz enucleated, and which I have recently examined. My experience in staining fully twenty-five sections of this material before I found one single bacillus illustrates one of the difficulties in this kind of work. The section of this material stained with hematoxylin-eosin explains the scarcity of bacilli in it, for it shows vigorous granulation tissue and an abundance of phagocytes. In such tissue tubercle bacilli are always hard to find. I would call particular attention to the character of the cellular infiltration in this process—large mononuclear leucocytes—in contrast to the cells which were shown in the anterior chamber of the eye that was destroyed by the serpent ulcer—polymorphonuclear leucocytes; and after seeing these two specimens, it is interesting to recall the views of Metchnikoff on phagocytosis—the large mononuclear leucocytes, as befits their slower and more unwieldy character, have a preference for animal cells and for bacteria of chronic disease, e. g., for tubercle and leprosy, while the polymorphonuclear leucocytes show a preference for the microörganisms causing acute disease. I would point out the fact that the anterior chamber, being practically a large lymph space with more or less fixed walls, has long been a particularly good region in which to study some of the general pathologic processes.

The next slide shows tubercle bacilli from a case of miliary tuberculosis of the choroid, and the next is a section from this case stained with hematoxylin-eosin, showing several foci of infiltration. I may say here that there is a great temptation in some of these specimens to point out interesting histologic features. I have resisted this so far as possible because of the time limit.

The next two sections illustrate difficulties that may be encountered in a search for bacteria in iridocyclitis or panophthalmitis. The section is from an eye sent to me for study by Dr. C. Zimmermann of Milwaukee, who enucleated it because of an acute inflammatory condition. It will be seen to have all the features of a bacterial process. In a search for bacteria, I stained and studied many sections. With Weigert's modification of Gram's method I found areas like the one illustrated by the next slide. I may say that more than one excellent bacteriologist, on examining this section, pronounced this a probable colony of bacteria. Without any question, these are not bacteria, but are granules of cells, probably mast cells. It will be recalled that mast cells are uncommonly abundant in the eye in inflammatory conditions, and it will be seen that, on account of the staining reaction of the granules of these cells, they here easily may mislead one. As was said, a thorough examination failed to demonstrate bacteria in this eye, although they must have been the cause of the acute process. This points to another possible difficulty in demonstrating bacteria in panophthalmitis, i. e., the bacteria may very quickly disappear. That microörganisms may quickly disappear has been experimentally demonstrated lately by Silberschmidt.[16] Working with a form of the hay bacillus, which caused panophthalmitis when injected into the eye of a rabbit, he discovered that on the third or fourth day after the infection the organisms could not be found in smears, and cultures remained sterile. In the case of the eye that I have just spoken of, it was removed four days after the general practitioner noticed that it was inflamed.

THE ESSENTIALS AND NON-ESSENTIALS OF OPHTHALMIC ASEPSIS.*

HAROLD GIFFORD, M.D.
OMAHA.

There are two fundamental propositions which should be kept in mind in our attempt to do aseptic eye surgery. First, that the conjunctival sac in the great majority of cases, and probably always, contains germs which are pathogenic, or which can, under certain conditions, become so. The white pus coccus is probably as constant an inhabitant of the conjunctival surface as it is of the skin. The pneumococcus of Fraenkel is frequently found there and probably occurs more often than most experimenters would have us think. I judge this to be the case from the difficulty with which it is grown and the ease with which its colonies are overlooked, when other germs are plentiful. The germ which occurs in the largest numbers in the conjunctival sac is the so-called xerosis or pseudo-diphtheria bacillus; and, although it is generally described as non-pathogenic, some of the best authorities regard it as a variety of the true diphtheria germ, and believe that, under proper conditions, it may become virulent. I have found it as the sole inhabitant of small abscesses in the lids, and Hala,[1] who has made the most careful study of the subject, believes it to be the common cause of chalazia. Kastalskaja[2] has found it in two cases of panophthalmitis, and it has recently been reported by Warnecke[3] as a cause of purulent otitis media.

The second premise to keep in mind is that to rid the conjunctival sac of these germs is a practical impossibility. This fact has been asserted often enough, but many operators still seem to dote on the idea that by rinsing out the sac with sublimate 1 to 5,000, or some other equally harmless mixture, they can obtain an aseptic operative field. In the latest work of that master of ophthalmology, Panas,[4] this notion evidently prevails, for he says: "The removal of the microbes and other impurities is not complete unless the lids are widely opened by the lid holder and the fluid, in the shape of a stream, is forced under them," etc. If there are any present who believe in the efficacy of such measures they need only make a few cultures from the retrotarsal folds of eyes that they have thus prepared for operation, to be convinced of their error. Furthermore, the germs can

not be rubbed out without injuring the tissues; and even if a small portion of the conjunctiva be everted and isolated by means of a Desmarres clamp, the area thus brought into plain view can be thoroughly wiped with moist swabs and treated with various antiseptics, and still, after waiting a minute or two, a scraping from it will show the presence of germs. The lashes also are a favorite abiding place for pathogenic bacteria. The main body of the lashes can apparently be freed from germs by thorough scrubbing with fat-dissolving agents, but none of these has any marked influence on the germs gathered about the roots of the lashes. I have tried all the most highly recommended methods and have found invariably that if, after the attempted sterilization, the lashes are pulled out instead of being cut off, a growth of germs, generally the white pus cocci, will be obtained from the roots. The method of Von Pflugk,[5] which consists in scrubbing the lashes with swabs dipped in benzine, is no exception to this statement. In the trials which I have given this method there has generally been no growth of germs from the shafts of the lashes; but from the roots germs have grown, as in all my previous experiments. I have said nothing about the tear passages because, while we recognize them as a constant possible source of infection, they could be cut off by one means of obliteration or another, if, by doing so, we should be certain of an aseptic field.

Starting with these premises, it is evident, I think, that a certain share of the precautions which general surgeons are apt to consider necessary, can, for the ophthalmic surgeon, be regarded as unessential or even to a certain extent detrimental. To begin with the bath: many operators in describing their technic refer with evident pride to their insistence on every patient taking a full bath. Now, while for esthetic reasons this may be eminently desirable, it seems to me that for an eye surgeon to have his patients take a full bath with any idea that he will on that account get better results from his operations, is on a par with the logic of the medicine man who beats a tom-tom to drive out the spirit of disease. Furthermore, the rigid enforcement of such a rule may occasionally lead to serious trouble. I have in mind an old Irish woman who, so far as I could learn, had never taken a full bath in her life, but who had, nevertheless, lived very happily and in perfect health to the age of eighty. On being sent to the hospital, the head nurse, as a matter of routine, had her stripped and put into the tub, and this unusual experience so excited the old lady that her mind became unbalanced and she was so unruly during her stay in the hospital that it was only through the purest good luck that she did not lose her eye. With regard to the preparation of the skin of the eye lids, it is obvious that the vigorous measures frequently employed in surgery to rid the skin of germs can not be used to advantage here, and unless the operation actually involves the skin, it is questionable whether the latter really needs any special attention, although there can be no objection to any such cleansing as can be done without irritating the eye. Where the skin of the lids is involved, besides scrubbing it carefully with sterile swabs, I think it advisable to paint the skin with 4 per cent. silver, allowing the latter to dry on. I have adopted this plan because I have found that by touching sutures with this solution once a day they can frequently be left in for a week or more without causing any suppuration, even if no bandage is applied. For cleansing the lashes, the benzine method of Von Pflugk is perhaps better than any other, but since it may be that some of the apparent efficacy of this method is due, not to the germs being killed or even removed by it, but to the remnant of some non-volatile impurity of the benzine being left on the lashes, I believe the safest plan in all operations on the globe is to cut off the lashes and, after scrubbing the roots with benzine swabs, to anoint them with an oxid of zinc or some other stable ointment, so as to hold in the germs which are invariably left on them. It may be asked why not pull out the lashes as recommended by Schiötz. My objections to this are that it is decidedly painful, and that it generally causes a marked reaction due, in my estimation, to the increased activity of the germs which must inevitably be left behind in the lash sockets.

The lid margin can apparently be temporarily sterilized by wiping it carefully with sterile swabs, though in doing this care should be taken to wipe away from the palpebral fissure and not to go over the same ground more than once with the same swab. All of these preparations, however, with the exception of cutting off the lashes, are probably non-essential for reasons which will be made evident when discussing the form of bandage.

The preparation of the normal conjunctiva, for an operation on the globe, should be conspicuous for its simplicity or even absence. Realizing that no plan has been discovered which will rid the sac of its germs, we naturally conclude that nothing must be done which will injure the conjunctival epithelium or excite any unavoidable irritation. All irritative antiseptics are worse than useless, and while I formerly wiped out the sac with a moist absorbent cotton toothpick-swab immediately before important operations, I found so many patients in whom even this simple procedure could not be carried out thoroughly without a certain amount of violence that I have abandoned it in all cases where the conjunctiva is entirely normal, limiting my interference with the conjunctiva to wiping it carefully at the point at which I intend to enter the knife; with the addition of an occasional irrigation of the field during and after the operation. As an irrigating fluid, a freshly made and freshly sterilized normal salt solution is probably the least objectionable, but in practice I generally use a boracic acid solution, since the salt solution, if kept in stock, is more apt to permit a growth of fungi which, though easily killed, might nevertheless render the solution somewhat irritating and unstable, while the boracic acid solution, if kept in a vessel with a layer of undissolved crystals at the bottom, is practically free from such growths.

Anything in the way of a preparatory bandage is to be abjured. Numerous experiments have shown that these always increase the number of germs in the normal sac. With regard to the tear passages, if there is any obstruction in the duct or inflammation of the sac, preliminary treatment should, of course, be instituted if there is a reasonable chance of restoring normal conditions in a short time; otherwise, as a preparation for a cataract extraction, it is probably better to extirpate the sac or close up the tear points with the galvanocautery; though I must confess that I have never attempted the latter procedure and have doubts as to whether the cautery will close the points as readily as some seem to imagine. In the case of patients who can be seen several days before a cataract extraction, I believe it is a good routine to slit the upper tear points slightly and inject some indifferent solution in order to be sure of the patency of the duct and the freedom of the sac from even minute quantities of pus; but where the patient must be operated on within twenty-four hours or so, if

5. Arch. f. Augenheilk., 45, 3.

the conjunctiva seems perfectly normal and there are none of the ordinary signs of obstruction of the duct or inflammation of the tear sac, this precaution may be omitted, since it is almost impossible to dilate either punctum without abrading the membrane; and any such abrasion, until entirely healed over, may furnish the breeding place which will convert a tolerably innocent germ into a pathogenic one. The practice of putting on a bandage twenty-four hours before an operation in order to test the condition of the conjunctiva and tear passages is, as I have previously suggested, decidedly objectionable. With regard to the bandage, there are, I think, very few who believe in using absolutely no protection for the eye after a serious operation. If our patients were all rational both when awake and when asleep this plan might be worthy of consideration, but as it is, I believe it to be a waste of time to discuss it. Whether to leave the eyelids entirely free under some sort of a shield is a more open question. It seems to me that it is decidedly easier for a patient to keep his eye still if a gentle uniform pressure is exercised on the lids, and the quieter the eye is kept for the first twenty-four hours and perhaps longer, the smaller the chance of secondary infection. I am aware of the claim that the action of the lids helps to rid the conjunctival sac of germs, and as previously mentioned, it is certain that in an eye not operated on the number of germs in the sac is increased by bandaging; but these considerations are more than outweighed, in my mind, by the rest which the binocular bandage secures to the operated eye; and as a matter of practical experience I have gained the impression that where an eye operated on is left open under a shield there is more apt to be an increase of secretion and irritation than where some sort of covering for the lids is used. The experiments of Genth[6] indicate, as one might *a priori* conclude, that the sterilization of the bandage materials is a matter of little moment. Genth made numerous operations on the rabbit's eye and applied bandages of cotton infected in the grossest way with pathogenic germs; and, in spite of this, obtained an infection in only six out of sixty-four cases. All of the infections occurred in a series of fifty operations in which the cotton placed next the eye was completely saturated with a fresh bouillon culture of virulent germs, while in fourteen other experiments in which the bandage cotton was infected in a number of places by wiping off the germs from a spatula dipped in the cultures, no infection took place. When we consider the exaggerated way in which these bandages were infected the conclusion is natural that under ordinary conditions the danger of infection from the average unsterilized cotton is so slight as to be hardly worth considering.

Not knowing just what process was adopted in the preparation of our best absorbent cotton and gauze bandages, I had several samples from standard manufacturers examined in the laboratory of the University of Nebraska in the hope that they might be found sterile. Portions of fresh packages of cotton and of gauze bandages were taken from the outside roll, from the inner rolls and from the ends, but with two exceptions germs growing on agar were found in all the experiments. The germs were not numerous nor were they of well-recognized pathogenic varieties, probably all belonged to the common atmospheric bacteria, but to allow for the possibility of some pathogenic germs being present, I have since then, as before, placed next the eye after all serious operations a layer of cotton which has been freshly boiled for ten minutes in a boracic acid solution. These experiments of Genth also indicate the slight importance of attempting to cleanse the lashes and the outside of the lids, although, on account of the real danger of touching the lashes with instruments, I believe, as previously stated, in cutting off the lashes.

There has never seemed to me to be any sense in sterilizing the roller bandage which is applied outside the cotton.

In deciding whether the cotton which comes next the eye should be moist or dry I have been influenced by the fact that the secretions from the conjunctiva never stick to moist cotton, while if there is any discharge under a dry cotton dressing it is always found stuck both to the lids and to the cotton. This convinces me that where there is any discharge containing mucus or pus, a moist dressing, or a dressing with some stable ointment, can alone be relied on to furnish good drainage. But if wet cotton is used it must, of course, be covered with rubber tissue or something similar to keep it moist. These, however, are matters of minor importance in comparison with the question of how best to apply the dressing so as to secure its prime object, namely, the protection of the eye from external violence and from infection by the patient's fingers. The best protection from external violence can only be secured by using one of the various shield dressings which provide an arch of some firm material, whether it be pasteboard, celluloid, gutta-percha, or metal; and to secure safety from the patient's fingers, nothing approaches the certainty afforded by pasting down the edges of the shield or bandage with thin strips of absorbent cotton and collodion.

The importance of distinguishing between the essentials and non-essentials of ophthalmic asepsis is in no way so well illustrated as by the various and, from a bacteriologic standpoint, heterodox methods employed by oculists in sterilizing their instruments. An operator who will insist on his patients taking a full bath and on sterilizing every scrap of bandage or cotton that comes within reach of the patient, will rely on some totally inadequate measure for sterilizing his instruments. In the paper by Panas, previously referred to, he says: "All objects used for bandaging, gauze compresses, silk threads, must be sterilized by steam at a temperature of 120 degrees for at least one-half hour. The absorbent cotton, whether in rolls or pledgets, is sterilized in tin boxes or wire baskets at a temperature of 150 degrees." This is not altogether necessary, but it certainly can not be objected to, but the sterilization of the instruments, the most important part of all, he dismisses with the following sentence: "All instruments of whatever kind must be previously immersed into boiling sterilized water to which has been added some bicarbonate of sodium which prevents rusting." Other operators put their instruments for a short time into one of the so-called antiseptic solutions. Now, there are few more pathetic things in the history of medicine than the innocent faith with which many excellent men, with no first-hand knowledge of bacteriology, have relied on the efficacy of everything that any investigator has seen fit to declare a germicide; and nothing has proved more deceptive than a vast amount of work which has been supposed to demonstrate the germicidal value of this or that chemical. The reason for this is found in the ease with which many germs, with their vitality in no way impaired, can be prevented from growing by minute traces of the chemical under investigation. And all the while we have in boiling water a disinfectant which all investigators agree in declaring infallible within certain limits. The comparative unpopularity among oculists

6. Arch. f. Augenheilk., 46, 2.

of the disinfection of instruments by boiling depends perhaps on the idea that boiling harms the keen edges and points of our instruments. I can not say that boiling has absolutely no such effect, but I do say that after having used the method for seventeen years, I have seen no evidence of it. That instruments are frequently injured while being boiled is true enough; but this is due, in my opinion, to their being rattled about together with the edges unprotected; while if the precaution be taken to wrap the points and blades tightly in cotton, no harm is done by the boiling itself. I have in my case a keratome which I have used at least a dozen times, boiling it from eight to ten minutes each time, which still cuts as well as the day that it came from the sharpener; but to obtain this sort of result, it is necessary also to have the instrument wiped and rewrapped immediately after it has been used. Boiling certainly spoils ivory or bone handles, but not those made of hard rubber, which I prefer to metal. There is one danger, however, which the disinfection by boiling opens the way for: If the instruments are not perfectly dry, a drop of fluid is liable to run down from the fingers to the eye; and to avoid this I have the instruments boiled immediately before each operation and have the water, while it is still boiling hot, poured out of the vessel; the heat which the instruments retain quickly drying off the moisture on the handles, the cover being replaced until the operation begins. A one per cent. solution of carbonate of sodium is perhaps as good as any thing to prevent rusting. Just how long the boiling should be continued is a somewhat open question. The ordinary pus cocci and probably all bacteria, except when in the form of spores, are killed by from one to two minutes boiling in a closed vessel. The spores of most, if not all, the germs commonly recognized as pathogenic are killed by about five minutes' boiling in a closed vessel; while, on the other hand, the spores of certain well-known saprophytes, such as the peptonizing bacilli of milk, will stand from ten to sixteen hours of boiling without apparent injury. Luckily, these germs are entirely harmless, but to allow for the possibility of some new pathogenic germs of unusual resisting powers being present, some compromise, such as a ten-minute boiling, has seemed to me reasonable, always, of course, boiling in a closed vessel. I will confess, however, that when in a hurry I sometimes boil the instruments five minutes only.

Collyria may, of course, be sterilized by boiling, but as cocain solutions lose their strength when boiled repeatedly, I sterilize a small quantity immediately before each operation, by suspending the tube which contains it in a pan in which the swabs for the operation are boiled for ten minutes. After the sterilization of the instruments it is not always so easy to keep them sterile until after the operation is completed, and, while it may seem superfluous, it will, I think, bear frequent repetition that the fingers of the operator, the skin, lashes and lid margins of the patient should all be regarded as more or less septic, no matter how carefully they may have been cleansed, and should not under any circumstances be touched by any instrument that must enter the globe; and the conjunctiva itself and the fluid in the sac should be touched as little as possible.

The management of the thread to be used for sutures is one of the most difficult tasks which the surgeon who wishes to be aseptic has to encounter. The threaded needles can be boiled with the other instruments if the silk be wound on bits of rubber tubing to keep it from getting tangled; but in introducing sutures into the conjunctiva it is very difficult to keep the thread from touching the lashes or skin of the eyelids, even if the patient wears a gauze mask.

With regard to the person of the operator, the full bath can, from a surgical standpoint, be classed with the luxuries, and the same may, I think, be said of the more elaborate attempts at disinfection of the hands, except in the rare cases in which the oculist must touch the tissues with his fingers. In my own experience, I can recall but three cases in which this has been necessary, the disease in each of these being a tumor of the orbit. It is now universally recognized that no method can be relied on to completely sterilize the hands, nevertheless the general surgeon tries to come as near the ideal as possible; but for the oculist it seems to me that anything beyond a good scrubbing with sterile soap and water and a careful drying on a sterile towel is a waste of time except in the rare cases mentioned. With regard to the dress of the operator, a surgical gown or jacket presents a good appearance and may be of some use, but it is far less essential than some form of protection of the nose, mouth, beard and hair, partly on account of the danger of dandruff falling directly on the operative field, but chiefly to hold back the germs from the nose and mouth which, as Flügge and his pupils have shown, are constantly shot out into the air while talking, coughing or sneezing. It is tolerably easy to have caps with face pieces made for this purpose, but nothing is so simple as a double thickness of gauze, about eight inches broad and a yard long. The center of this is placed over the nose, mouth and chin, and the ends crossed behind the head and brought around so as to cover the vertex and forehead as well.

I have thought it best to discriminate against the non-essentials in ophthalmic asepsis because if the methods are simplified there is a better chance that the essentials will receive the scrupulous attention which they deserve.

A paper of this kind necessarily deals with tedious details, and if it has seemed unusually tiresome I can console you with the assurance that I could easily have made it much more so without exhausting the really important features of the subject.

DISCUSSION

ON PAPERS OF RANDOLPH, PUSEY AND GIFFORD.

Dr. Casey A. Wood, Chicago—There is one condition from which it seems to me especially desirable to protect the eye: chronic dacryocystitis with dilatation of the sac and infection of the canaliculus and parts surrounding it, in any operation that involves the opening of the eyeball. I have recently had two cases where I was faced by this problem. It was not possible to treat the condition according to the Hirschberg method for two or three months. I have the same objection that Dr. Gifford referred to in speaking of the use of the galvanocautery. I also object to the extirpation of the sac; it takes too long to heal. I have resorted in a few cases to a little device mentioned by Knapp in his article in Norris and Oliver's System, i. e., shutting off the canaliculi by means of a simple suture, the thread being passed around the canaliculi as near the puncta as possible. No harm results, the suture does not cut through within nine or ten days after the operation, so that the wound in the cornea or sclera has time to heal. My two cases (of chronic dacryocystitis with double cataract) acted so nicely that I can recommend it to you as a simple and efficient device. Before tying the canaliculi I in one case filled up the sac and canaliculus with argyrol; and when the sutures were removed the brown fluid flowed out from both puncta, showing that no adhesion of the walls of the small canals had taken place at the site of the sutures.

Dr. Ira J. Dunn, Erie, Pa.—Dr. Randolph speaks of the action of streptococci not being persistent. I would like to

report a case in which they were to me painfully persistent and active.

A foreign body had remained in the cornea for nearly a week. The eye was treated after removal of the foreign body one week when the patient was sent to me. A large sloughing ulcer had formed near the center of the cornea. It was cleaned and cauterized. and iodin, iodoform, etc., were applied in the very careful manner so fully discussed and advised in this Section last year, but with no avail.

The eyeball perforated, panophthalmitis resulted and the eye was enucleated. Infection of the orbit followed, and this extended to the lower lid. The cheek and neck of the corresponding side became swollen and edematous. The opposite side was involved also, but did not slough. Temperature rose above 103. It was in an elderly subject and there was much discomfort and nervous agitation from the systemic disturbance. Three doses of antistreptococcus serum were given within a few hours and after the first dose the temperature began falling, the progress of the orbital inflammation began subsiding and the patient became quiet and comfortable. While there was a large slough in the lower lid there was no further anxiety and little deformity resulted, an artificial eye being comfortably worn.

DR. W. H. DUDLEY, Easton, Pa.—For some time I have been in the habit of making an examination of the secretion of inflamed conjunctivæ, and within the past few weeks two cases have come to my office which have demonstrated the importance of doing this as a routine measure in any suspicious case. There is a certain class of cases in which the acute conjunctivitis with the Weeks bacillus will produce a very severe attack. There is usually very little difficulty in diagnosticating a case of gonorrheal ophthalmia, though it may occur.

The first case I refer to was one of gonorrheal ophthalmia, and examination of the secretion in the office at the time showed at once any number of the organisms of Neisser.

A week or two later one of the physicians of our town came in with his lids and conjunctiva swollen almost a duplicate in appearance of the former case. I asked if he were treating any patients with gonorrhea, and he said he was, several. The condition looked alarming. I made an examination of the secretion at once and found it consisting of a pure culture of the pneumococcus. Of course we were both greatly relieved, and this demonstrates the usefulness of making these examinations of the conjunctival secretion when there is a possible question of its character.

DR. ADOLPH O. PFINGST, Louisville, Ky.—This subject is of the greatest importance to all of us. The mere fact that the conjunctival folds harbor such pathogenic organisms as the streptococcus, staphylococcus and pneumococcus is a point that should make us consider carefully a thorough sterilizing of the sac. I believe we should carefully cleanse the conjunctival surface of the lids and the edges. We should get out hands as sterile as possible and be prepared in every way just as the general surgeon is. We should leave no possibility of getting these germs into our wound. As to the sterilization of instruments I think the heat doesn't affect the edge of the knives as much as is usually supposed. The dullness is caused more by the operation, cutting through such tissue as the cornea than it is by the boiling.

DR. A. R. BAKER, Cleveland, Ohio—It has been my custom for many years to wrap my knives and forceps in cotton and place them in boiling water. I boil them only a short time. Then while waiting for the anesthesia I amuse myself by wiping the points of the instruments with bits of sterile absorbent cotton held between the forceps in the boiling water. I adopted this practice many years ago from some experiments made for me by a young bacteriologist. We had fewer growths with this way of cleaning the instruments than with any other method. This method of wiping the knives has proven to be sufficient to remove the bacteria.

DR. E. C. ELLETT, Memphis, Tenn.—I would like to mention a method I recently adopted to prevent infection in case of cataract extraction. The case was one of incurable conjunctivitis due to a mixed infection of the staphylococcus and pneumococcus, and the method I resorted to was this: preceding the operation I incised the conjunctiva all around the cornea and dissected it up from the eyeball for a space of about a half inch away from the cornea. I then did the operation of extraction, and picking up the edges of the conjunctiva brought them up over the cornea and sutured them in that position. There was not an undue amount of reaction. The sutures were removed on the fourth day, when the corneal wound was healed and the conjunctiva eventually slipped back to its normal position. The patient got vision of 20/30 without a needling operation.

DR. W. R. PARKER, Detroit—I want to mention one case on which I operated after the method of Dr. Ellett. Without going into details, I followed his method, suturing the conjunctiva over the entire cornea. The sutures were removed on the third day. At the end of the second day after sutures were removed the whole lower portion of the cornea was exposed, and on the third day the whole cornea. Vision was 20/40.

DR. J. H. CLAIBORNE, New York—The health and vitality of the patient have much to do with the healing of cataract wounds. I had one case that illustrates this very well. An old man of seventy-two, apparently healthy, with clean conjunctiva, was operated on by the combined method. The wound remained unclosed for nine days, and at the end of that time became infected. Inside of ten days or two weeks he developed acute nephritis. I could not trace any source of infection, and could only assume that his vitality had been very much lowered and his tissues were unable to resist the presence of the bacteria in the sac. The older Critchett used to say he would never do a corneal section where the patient was not in good health.

DR. HAROLD GIFFORD, Omaha—In regard to Dr. Ellett's method, while I do not question its originality so far as he is concerned this is a tolerably old idea. De Wecker recommended the purse-string suture for protecting corneal wounds and Kuhnt has been recommending a flap drawn down from above as a protective measure in some cataract extractions. For the last three years I have been using a modification of this method, putting in a purse-string suture beginning and ending at the lower margin of the cornea, but dissecting up only the upper half of the conjunctiva. The suture is thus ready to tighten the instant the extraction is finished, and still the lower part of the cornea is left free. I have used the method in four or five cases of dislocated lens with good results. I have also used it in one case of cataract extraction with dacryocystitis, without a trace of infection.

As to the method referred to by Dr. Baker of sterilizing his instruments, there is no doubt that if you use sterile cotton in this way you can get off most or all of the germs. At the same time you can not tell but what you may just loosen up some of the bacteria which do not come away on the cotton but are ready to come away on your tissues. I think it is certainly safe to boil the instruments for ten minutes. Of course some of the more resistant spores can not be destroyed in that time, but the ordinary pathogenic germs are killed in a few minutes by boiling in a closed vessel; and in ten minutes you can be reasonably sure that your instruments are safe.

He Can Not Afford It.—No man, irrespective of the amount of work he is doing, can afford to remain out of the medical society in his county. He needs the society and the society needs him, and his active work in the society means a broadening of the influence and sphere of usefulness of both. Too many medical men are now in a rut for want of the influence and advantages offered by contact with other medical men in medical societies, and it is to reach such a class of men and to stimulate active members of medical societies to increased effort, that the organization scheme has been proposed by the American Medical Association. The movement is in the right direction and should receive the encouragement and support of all physicians who have their own interests as well as the interests of the medical profession at large in view.—*Ft. Wayne Med. Jour.-Mag.*

SOME CLINICAL ASPECTS OF TUBERCULAR PERITONITIS.*

JOSEPH EICHBERG, M.D.
CINCINNATI.

Among the many startling results that have followed the introduction of laparotomy, exploratory or curative, none shows a more decided departure from beliefs of a former generation than the present attitude of the profession with regard to tubercular peritonitis. The surprising clinical fact, recorded by Sir Spencer Wells, that a case of tubercular peritonitis, accidentally opened under a mistaken diagnosis of ovarian tumor, should not only recover from the immediate effect of the operation, but promptly go on to apparent recovery, and end in perfect restoration to health was so anomalous a history that it savored of the miraculous. This was before the days of bacteriology, and while the battle as to the single or dual nature of tuberculosis was a great pathologic issue. With the knowledge of the bacillus as the one essential feature in causation, and with the great advance in surgical technic, the pathologic relations, as well as the clinical features, have received a more critical study, and much light has been gained.

Brunn[1] gives a most comprehensive review of the literature of this subject from 1885-1900. Our knowledge may be said to have reached its greatest development in this period. Many of the tables and references are taken from an analysis of this review. Of some 28,000 cases coming to autopsy, many of these were healed, many showed co-existing diseases of other organs. Tubercular peritonitis was found in 2¾ per cent. As early as Morgagni we find descriptions of tubercular peritonitis, with the significant statement that it frequently occurred with pulmonary tuberculosis, and a suggestion of the similarity of adhesions here formed with those observed in the pleuræ and pericardium. Almost a century of study has thus been given to this particular form of tubercular disease.

The peritoneum may be one of the sites of local manifestation of a generalized miliary tuberculosis, but the term tubercular peritonitis is generally understood to apply to the chronic form of the disease, which in a measure constitutes a distinct affection. Even here the process is usually secondary to disease, appearing primarily in some distant part, most commonly the lungs; or the peritoneal involvement may follow by direct extension or by dissemination through the lymph paths, or by a simple process of grafting from a previously ruptured tubercular focus having access to the peritoneal sac, and sowing, as it were, the elements of the disease over the entire membrane.

As primary foci near the abdominal cavity may be mentioned psoas abscess, caries of the vertebræ, tuberculosis of the genitourinary tract in both male and female, including the suprarenal gland, tubercular ulceration of the intestine, solitary tubercle of the spleen, and tubercular disease of the retroperitoneal glands. Some cases of tubercular peritonitis appear to be primary, as shown partly by the manifestly greater age of the diseased parts of the peritoneum when contrasted with the evidence of tuberculosis in the other organs, in part by the absence of any other discoverable tubercular deposit. In children the appearance of primary tubercular peritonitis is more frequent than in adults; of 22 cases reported by Rilliet and Barthez, 12 were classified as primary.

Tubercles may be distributed uniformly, more or less thickly set, over the entire peritoneum, or they may form nodular masses of varying sizes which undergo caseous or ulcerative changes, and thereby furnish the nucleus of secondary daughter tubercles in the vicinity.

With such multiplicity of lesions, and with the symptoms of the primary pathologic process complicating most irregularly the clinical picture of the peritoneal affection, it is not surprising that there should be a wide range in the symptomatology. On the basis of the postmortem findings various classifications have been made. The simplest recognizes two forms, the dry and the exudative, including under the latter head the caseous and the purulent varieties.

From a clinical standpoint Hawkins divides all cases into four varieties:

1. Latent.
2. Severe, with ascites and a spontaneous tendency to remissions or encapsulations.
3. Cheesy purulent form, with frequent formations of large caseous masses and adhesions.
4. Fibrous-adhesive form.

The French and English authorities generally describe three varieties:

1. Ascitic.
2. Fibro-adherent.
3. Ulcerative form with or without suppuration; while Galvani gives five, and Aldibert has some eleven subdivisions.

Judging by inoculation experiments, differences in the pathologic product of the bacilli depend in some degree on the source of infection. Injection into the peritoneum made with fluid obtained after weakening of the bacilli in sputum by exposure to a temperature of 60 degrees, produces rather the fibroid; the use of a fluid rich in bacilli or of unemulsified sputum, the cheesy, purulent variety.

Injection of the first tuberculin of Koch produced no reaction, whereas the tuberculin R caused proliferation of the intestinal serosa.

The general symptoms of tubercular peritonitis are pain, fever, emaciation, anemia, anorexia, to which are to be added as more purely local manifestations, change in the contour of the abdomen, ascites, diarrhea, or constipation; and, occasionally, redness or inflammation about the umbilicus, with possible perforation and formation of a suppurating sinus or of a fecal fistula; profuse and very exhaustive sweats occur in the caseous and ulcerative varieties. Of physical signs, the most important may be properly said to be the alteration in the impressions conveyed by palpation, whether in the dry or exudative cases. In children, particularly, the examiner is apt to be impressed by the manifest malnutrition, so that there is a striking contrast between the distended abdomen and the general emaciation. With the patient on the back and the abdomen relaxed to the utmost possible extent, there will usually be noted an oval or round distension of the cavity, very different from that due to ascites, arising from other causes. There is not the tendency to bagging in the groin, or above the iliac fossa. If liquid be present, it is rarely perfectly free in the abdominal cavity, being bounded in one or other direction by firm adhesions. After absorption of this fluid the exploring hand experiences a sense of tension or hardness in the abdominal wall, a peculiar elastic resistance, which, according to Grisolle,

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

1. Cent. f. allg. Path. u. Path. Anat., 1902.

is found in no other malady, and which has been described by DeMussy as an incomplete elasticity with resistance, as though the hand were plunged into firm dough.

In addition to this the abdominal wall may, over certain areas, give an impression of plaque-like thickening, there being in these places increased induration and resistance. Palpation should always be made by laying the whole hand gently yet evenly on the abdominal wall, and then carefully indenting the fingers, preferably moving all the fingers together, so that no indentation of the walls occurs at any one point. In this maneuver it will occasionally be found that adhesions and loops of intestine, particularly when distended, may simulate tumors, especially in the region of the cecum. Occasionally loops of intestinal coils may be seen and felt through the thinned muscular wall; this is exceptional. Palpation will also show the presence of fluids, which may or may not obey the law of gravity with the patient's change of posture.

Attention has already been directed to the cases with exudation as constituting a special class; yet the value of such classification may well be questioned, when it is remembered that in very many cases the presence of abundant fluid constitutes rather a phase than a form of the malady. In children, for the most part, and in many adults, the so-called ascitic form is only transitory, and the fluid is later resorbed; so that the value of effusion as a symptom may depend on the period at which the case is seen. It may even happen that as the effusion disappears, the contour of the abdomen changes, though a permanent meteorism usually occupies the space occupied by the fluid. Thomayer has called attention to a physical sign of some value. In the shortening of the mesentery resulting from tubercular infiltration, retraction takes place toward the base of attachment, so that the entire mass of intestinal coils, when not previously adherent, is drawn upwards, backwards, and to the right, while the fluid exudation accumulates below, and to the left.

By this change the symmetry of the abdomen is often disturbed, as may be verified by inspection, palpation and percussion. Palpation will also disclose the presence of the transverse induration about or just below the level of the umbilicus, due to the infiltrated and curled-up omentum. This sign is wanting where, as often happens, previous adhesions have fixed the omentum to some of the pelvic viscera or to its brim. Where tubercular ulceration exists, particularly if multiple, movable cylindrical masses, in reality the hose-like, greatly infiltrated intestine can also be outlined. In some instances a distinct friction rub, either localized or more general, will be noted; it may be a very mild friction, what the French writers term starch-like, *amidonienne,* or an unmistakable harsh, rasping rub. Auscultation may be employed to control or check the results of palpation. During palpation one observer describes the condition as suggesting that the abdominal wall and subjacent viscera, firmly united by adhesion, could not glide over each other. The friction rub is felt more frequently in the upper quadrants. Percussion corroborates the presence of the fluid, and its data should be carefully noted. It will inform us as to whether the fluid is movable or sacculated in small pockets, as often happens; according to Grisolle, in one-tenth of the cases.

A careful record of the areas of dullness should be kept from day to day, for, as Christie has remarked, a striking feature consists in the atypical character of the percussion data, changing slowly and imperfectly with change of posture, but often varying spontaneously. It can usually be determined that the quantity of the fluid is inconsiderable; it may amount to 2 or 3 liters, but never equals the enormous amounts encountered in cases of obstructive lesions of the portal vessels.

Of the general symptoms fever is perhaps the most inconstant. It may be encountered at one stage of the disease (usually in the earlier periods) to disappear for many weeks or months and return when ulceration takes place in some of the caseous masses. The number of observations on the temperature is not very extensive, yet enough has been collected to show the frequent absence of fever in cases where the diagnosis has been confirmed by autopsy or by laparotomy. It has been absent in the majority of my own cases. In 16 cases observed by Hinterberger there was fever following the operation in 14; five times it had existed before, 9 times it developed for the first time after operation, and two cases remained afebrile throughout. In several cases occurring in my own practice, other physicians, while inclined to the diagnosis of tubercular peritonitis, had found the absence of fever an insuperable barrier to such a conclusion. High fever usually accompanies ulcerative tissue destruction. Pain may be entirely absent. It occurs in the majority of all cases; it is oftentimes constant and fixed, though it may change both in intensity and location. Its development is often very gradual, consisting at first in a sense of uneasiness, which becomes accentuated where any weight rests on the abdomen, and is certainly felt on pressure. Despite the fixity of the lesion, the pain may be erratic, and its maximum intensity may not correspond with the location of the trouble. When not spontaneously present it may often be developed by suddenly releasing the abdominal wall, previously depressed by firm and gradual application of the flat of the hand, as suggested by Henry. In adults persistent abdominal pain, with no other symptom than progressive emaciation, would suggest a possible tubercular peritonitis. The tenderness over infected viscera may become extreme.

Diarrhea is the regular accompaniment of tubercular ulceration of the intestine, but in other forms constipation is the rule. There may be but one movement daily, but the dejections are liquid, and this fact may be utilized in diagnosis. In children the stools are often acholic (Berggrün and Katz), though there is no jaundice or bile-coloring matter in the urine, the clay color of the stools being due to excess of fats. On the other hand, the constipation may be most aggravated, and may go on to complete intestinal obstruction, due to the pressure of strands of adhesion, twisting or paralysis of the bowels, or the formation of large tumor masses in which intestinal coils become adherent. The obstruction usually ends by yielding either spontaneously, or with medication, after some days. Death has resulted, the end coming slowly after twenty to thirty days. Anorexia is frequent; vomiting, especially in children, is very rare.

Periumbilical inflammation may occur in other forms of suppurative peritonitis, but is most frequently due to tuberculosis. From this hasty summary, it will appear that there is no absolute sign that clears the diagnosis, which is often to be made only by exclusion. Age has a most important bearing. While exceedingly rare in children under one year of age, one case only in 300 collected by Carr, the early periods of life contribute the largest contingent, a fact frequently overlooked because of the tendency to spontaneous cure; it is infinitely the

most common form of peritonitis between the ages of six and ten, and, though beginning acutely, may soon become subacute and thus continue throughout.[2] Spontaneous cure has baffled many students; yet no one would to-day repeat such a criticism as this of Siredey: "We believe that Hilton Fagge suffers from a strange illusion when he says that the majority of children suffering from tubercular peritonitis may be cured by mercurial liniments, and we hasten to add that such observations as he has cited in support of his views are absolutely valueless." It is difficult to divorce from the professional mind the idea of necessary fatality in connection with tuberculosis of any internal parts.

In doubtful cases with ascites, the withdrawal of fluid has been recommended for agglutination and inoculation tests. Benedix claims to have found a positive agglutination test in a dilution of one to ten, while a non-tubercular ascites failed; both conclusions were corroborated by autopsy, the second case showing cirrhosis. The inoculation test in lower animals would, however, appear to be the main reliance. Bacteriologic examination of the fluid withdrawn may show nothing, yet the same fluid will promptly give rise to an inoculation tuberculosis in guinea-pigs. A most important factor in diagnosis is the coexistence of tuberculosis in other localities, particularly tuberculosis of other serous membranes. Aran has formulated his view that tuberculosis of the peritoneum often is a part of a more generalized process affecting serous membranes. Goddier says: "Where there is tuberculosis of the peritoneum, there is always tuberculosis of one or both pleuræ as well," and other observers have directed attention to what is termed an isolated tuberculosis of serous membranes. As the starting point for this form of tuberculosis is often found in the genital tract, a very careful examination of these organs is essential. In women nodular masses of varying sizes will frequently be found in and about the pelvis.

Laparotomy does not always establish the diagnosis. Even with the entrails exposed, error is possible. Echinococcus vesicles, the eggs of the tenia, and simple cell inclusions have all given rise to tubercular formations, whose macroscopic diagnosis was impossible. The nature of the fluid is often suggestive, the sacculation of the exudate, the whitish opacity or bloody tinge of the liquid with its viscid, jelly-like consistence, all argue for tuberculosis; absolute certainty is, however, only possible with the microscope or inoculation test; but tuberculosis may be generally assumed as the cause of nearly all nodular tumors, merely on the doctrine of averages.

We now come to the question of laparotomy. The example of Spencer Wells, of performing an operation under a mistaken diagnosis, for a condition which then promptly improved, has been unintentionally repeated several times, and probably will continue to be repeated. Too much credit for the recovery can not fairly be assigned either to the operation or the operator. König undoubtedly is responsible for the popularization of laparotomy as an element in the treatment; and since his day there have been many undoubted cases, as shown by autopsy or by survival for many years of healed tuberculosis following abdominal section. Indeed, some cases are on record of coexisting tuberculosis of other organs, in which, following operation, these additional lesions presented notable improvement. Has this not been another instance of the *post hoc*? The operation is constantly urged by the surgeon, and Pribram goes so far as to advise its performance in every case, which shows no improvement after a few weeks of medical treatment, even where there is a pulmonary complication.

Good results have followed simple incision, irrigation of the cavity, drying of the peritoneum, resection of diseased parts, and other modifications. The essential feature seems to be an incision, even when not carried into the cavity; for there are many cases in which the cavity no longer exists. Some regard as essential the mere access of air, and Mosetig, to be on the safe side, merely punctured the abdomen, and then inflated it with sterilized air, thinking thereby to impart some altered quality to the bacilli. Then it has been held with unconscious humor that the opening of the abdomen allows of such rapid drying that the bacillus dies. Others regard the effect as due to more pronounced reaction of the serous membrane after operation. In cases with ascites the mere mechanical relief following withdrawal of the fluid can be easily understood; the diminution of pressure may also allow better conditions for resorption and improve the circulation. It is a widely entertained opinion that operation assists the peritoneum to more effective isolation of tubercular foci by stimulating the growth of new formed connective tissues. Another more modern theory would explain the action by the agency of antitoxins, whose formation is started by the operation, or of alexins generated in the blood; while another view attributes the improvement to the actual escape of the bacilli and their spores through the incision the moment they have a chance to get out!

After all this elaborate effort at explanation, the true answer to the question as to why laparotomy cures tubercular peritonitis, is: "Because it does not." The percentage of recoveries without operation, for all ages, and with or without complications, is greater than with operation. This is admittedly true of all forms except that with effusion, and here the results of medical treatment have been most satisfactory; for these are the cases which tend most commonly to spontaneous cure. In the course of five and a half years Herringham observed twenty-five cases diagnosed as tubercular peritonitis, of which nineteen recovered without operation, and three were unimproved. He finds the only justification for operation is a return and increase of the ascites, after puncture. Hawkins reported fifty-nine recoveries, all but three of whom were treated by internal medication. From a collective report of 112 cases treated by operation, Hawkins concludes that the percentage of recoveries is as great without as with operation, the indication for which is furnished by the presence of marked ascites. The distinguished surgeon, Czerny, cautions against expecting too much from the operation, whose mortality in his hands has been very high, for out of ten cases operated on, but two survived after three months. Leyden asserts that operation furnishes no better results than can be secured without it. He attaches little importance to experimental inoculation or the detection of the bacillus, and thinks general symptoms sufficient for the diagnosis. Where abdominal tension from fluid is great, he recommends occasional punctures. According to Pic, the ulcerative form may heal in children, never in adults; the fibroid form heals in both, and the form best adapted for operation is tuberculosis with ascites. Wheeler declares that the operation is absolutely contraindicated where there is no exudation in the abdomen, or where there is abundant development of nodules and bands, or where there is marked tuberculosis of other organs, especially intestinal ulceration. With this view

2. The proportion of the sexes is nearly equal before ten years, but the female sex furnishes a much larger contingent after this.

I am heartily in accord. Wheeler also advises against drainage, owing to the likelihood of a fistula, fecal or tubercular.

The operation has been particularly recommended for exudative cases in children, but in the last number of the *Archives of Pediatrics*, Guthrie gives a summary of some personal experience showing recoveries with and without operation in the ratio of 16 per cent. to 50 per cent. His language in condemning the operation is not without a tinge of bitterness.

Jaffé has shown that many cases reported as cured still contained at the time when they subsequently came to autopsy, smoldering foci of tubercular disease, which required apparently but the merest accident for general dissemination, or for reappearance of the local process in active form.

The opinion that a diagnosis of tubercular peritonitis calls for immediate laparotomy is certainly erroneous, not to say vicious. It would be responsible for many deaths. In the hands of the most skilled surgeon the mortality incidental to the operation *per se* is not less than 10 per cent. Cases requiring relief by operation can be temporarily improved by simple puncture and withdrawal of the fluid. The majority of such cases under the tonic regimen will end in recovery without operation. It will be found that some cases will disappoint every expectation of improvement, under any plan of treatment, and again complete recovery will follow under conditions apparently most unpromising. What the particular factor is that determines the issue must still be doubtful, but increasing experience and most careful analysis of figures would lead us to place it in that unknown chemical and physiologic property, the native resistance of tissues. We may assume a variability in the toxic properties of bacilli, even as we see variations in structural details; and this variability plus the equally variable inherent constitutional resistance gives us our equation, whose resultant is naturally most inconstant. It is certain that the peritoneum, perhaps even in greater degree than most other serous membranes, possesses the property of finally disposing of the tubercle bacillus, by a process of fibroid inclusions, so effective that it not only results in a limitation of the infected area, but often in the actual destruction and disappearance of the pathogenic germ. We find ourselves coming back to the standpoint, which Virchow investigated in his studies of the "combat between the cells and the bacilli," and, while sparing no endeavor to limit the possibilities of entry of the bacillus, and to render innocuous those sources of infection easily controlled, it will be found that our best weapon lies in so fortifying the cells which, in the final test, must bear the brunt of the fight, that the natural processes of reactive inflammation may lead to the development of organized fibroid tissue. As in the fight against tuberculosis in the larger arena, so here the solution will be found in giving to the patient, in greatest abundance, good food, pure air, unbroken rest, and ease of mind. It is not that we would slight the surgical management of such cases; but surely that science is best which by early recognition of diseased conditions and prompt institution of appropriate remedies protects the patient from the necessity of submitting to the hazard of operation, with the possibility of no permanent relief. Immediate recovery from the effect of the operation can not be counted an advantage. It remains for collective investigation to show the percentage of patients in good health six months after the operation, before determining the position of laparatomy.

As illustrating somewhat different types, I append a brief history of the following cases:

CASE 1.—Discrete tubercles of peritoneum, probably secondary to appendicitis, with ulceration discovered at operation for appendicitis. Recovery.

S. R., aged 12. Has had repeated attacks of appendicitis, some very severe, others of less duration and intensity, coming on as often as every two months in the year preceding operation. Boy always pale, thin and feeble. Bowels habitually constipated; no appetite. In intervals between attacks no tenderness of abdomen, no induration or sensitiveness anywhere about abdomen. Operation for removal of appendix in February, 1892. Appendix thickened, surrounded by adherent omentum and intestinal coils, small perforation with sacculated cavity containing a few drops of pus. Neighboring loops of small intestine, and parietal peritoneum showed limited number of gray nodules, firm, translucent, surrounded by a pigmented crescent, but apparently giving rise to little, if any, local reaction. Recovery after operation prompt. No subsequent symptoms except slight hernia in line of incision relieved by second operation. Young man to-day enjoys excellent health. There was no family history of tubercular disease; no signs of pulmonary or other involvement preceding operation.

CASE 2.—Generalized chronic tubercular peritonitis, with special localization about liver, producing chronic perihepatitis. Ascites. Repeated puncture. Death.

J. H. patient male, aged 54, single; generous liver. Family history good. History of persistent alcoholism, never carried to excess. Taken sick with sudden pain in abdomen, most marked in right hypochondrium; chills, fever of intermittent type; anorexia, constipation, gradually increasing distension of abdomen, dyspnea, emaciation, anorexia, subsidence of fever, but increase of abdominal swelling. No cardiac or renal disease; no jaundice. Physical examination shows abdomen distended with ascitic fluid, freely movable. Liver dulness not easily made out. Some tenderness or palpation over abdomen. After withdrawal of 2½ gallons of straw-colored fluid liver dulness found to be slightly increased. Abdominal walls apparently thickened and unusually resisting. No fever. Reaccumulation of fluid in very brief period. Death six months after onset of symptoms from exhaustion. Autopsy confined to abdominal cavity. Chronic perihepatitis (capsule thickened so as to measure half an inch), generalized tuberculosis, parietal peritoneum about one-quarter inch in thickness, intestinal coils showing few adhesions. Retroperitoneal glands enlarged, reddened, no tubercular infiltration. Diagnosis corroborated by microscopic sections.

CASE 3.—Dry adhesive peritonitis with caseous salpingitis. Operation. Final recovery after prolonged suppuration from tubercular sinus.

L. B., aged 21, dressmaker. Fairly well nourished, single. Family history, several deaths from tuberculosis in direct ancestry. Never been very robust, menstruation at 15, fairly regular, painful. Appetite poor, chronic constipation. No fever. Some pain in back and tenderness over abdomen. Physical examination, no pulmonary involvement. Abdomen oval, distended, rather resistant, no mass or induration. No fluid. Diagnosis, tubercular peritonitis. Under general measures and attention to bowels some improvement. Four months later patient passed through attack of typhoid fever of moderate severity, during which persistent abdominal distension was most distressing symptom. Complete recovery from typhoid. Pain in abdomen dull, heavy and variable, continued. Operation. General matting together of all viscera; omentum stretched tightly in front had to be detached from borders of pelvic cavity, showing caseous tuberculous infiltration and softening of both tubes, several tubercular abscesses in pelvic cavity. Following operation patient has gained some in weight, the temperature slightly lower in range, but still persistent. Exudate still being poured out, however, showing the process still active.

Removal of adnexa, cleaning out of tubercular debris, irrigation and drainage. Tedious recovery and persistence of dis-

charge from sinus left after removal of drainage tube. Irrigation of fistulous tract with zinc chlorid solution; no effect. Following use of small quantity of peroxid of hydrogen, marked and sudden increase of pain in abdomen with collapse, probably giving way of adhesions due to pressure of liberated gases when peroxid reached deeper parts of tract. From this time on marked aggravation of symptoms, increased discharge, great pain on movement, some fever, final and complete recovery about five months after operation.

Case 4.—Chronic tubercular peritonitis with sacculation by formation of an artificial diaphragm across lower part of retracted intestines and mesentery. Operation for movable kidney a year earlier showed no tubercular disease in abdomen. History furnished by Dr S. P. Kramer, with whom this case was seen in second operation. Tubercular fistula, still discharging.

Mrs. E. T., housewife, aged 33. Mother of five children, all healthy. One brother dead from tuberculosis. Other family history negative. March 20, 1902, operated for floating kidney, right side. At that time pelvic organs normal. Present illness of about six months' duration. Abdominal distress, intestinal indigestion, great deal of flatus and pain in bowels. For past two months gradually increased dropsical swelling in lower part of abdomen. Temperature ranges from 99 F. in morning to 101 in evening. Examination shows fluid in abdomen, serous in character. Confined to lower segment of abdomen and pelvis. Abdominal walls tense, protruding; eversion of umbilicus, no tumor discoverable. Bowel resonance does not change when position of patient is changed. Abdominal walls thickened by peritoneal deposits. Ovaries and tubes matted together so that they can not be palpated. Menstruation regular and normal. Urine normal. Feb. 12, 1903, laparotomy. Ovaries and tubes markedly tubercular; parietal peritoneum, having deposits of tubercles and tubercular hypertrophy. Pelvic organs separated from intestines by about three quarts of bloody serous fluid, which became partly gelatinous on exposure. Above the fluid there had formed a diaphragm of adhesion completely walling off the intestine from the cavity occupied by the fluid.

Ovaries and tubes removed. Abdomen closed without drainage. Primary union. On the twelfth day discharge from the lower angle of wound of about half pint of same fluid as before. At this point there formed a fistula the size of a pin head, which continued to discharge serous fluid up to date of discharge, March 14, 1903.

Case 5.—Tubercular peritonitis wih slight ascites. Chronic pleurisy, operation, no improvement. Occurred in gynecologic service of my friend Dr. Withrow at Cincinnati Hospital.

E. Y., female, aged 32, housework, colored. Family history not known. Menstruation at 16, regular, lasting four to five days. Complains of pain in abdomen, especially low down in left side, extending down left leg. Some backache coming on in paroxysms; never pregnant. Admitted to Cincinnati Hospital Jan. 18, 1903. Unable to work for three months past. Swelling of abdomen began about three weeks before admission so severe that she could not wear her clothes. Swelling at first more marked on left side. Swelling varied from time to time. Not much pain. T. 100.2, P. 108, R. 24. Slight tendency to constipation. No appetite. Some resistance on palpation over lower half of abdomen, where resistance is more marked, where there is no tenderness on deep pressure. On day after admission dulness over left lower quadrant; remainder of abdomen tympanitic. Enema to unload bowel did not change physical signs. Next day dulness had completely disappeared. Vaginal examination negative. Evening temperature 102. Five days after admission dull area in lower left quadrant again present, extending somewhat beyond median line to right. Two days later dull area on left side does not reach to median line. I saw the case eleven days after admission. There could then be made out a small quantity of fluid in left chest, an indurated mass lying transversely across abdomen just below umbilicus, about 1½ inches in thickness, 4½ inches in length, not tender, slightly movable. Peculiar doughy elasticity of abdominal walls. Evening temperature reached 104. Laparotomy February 4. Incision 1½ inches in length in median line. Peritoneum thickened and gelatinous. About a quart of straw-colored fluid escaped. Peritoneum everywhere thickly studded with tubercles, those in the pelvis larger than on intestinal or parietal layers. Wound closed. Union by first intention. Apparently nothing gained by operation. Temperature ranges for next month, during which time patient was under observation, continued same as before.

Case 6.—Tubercular peritonitis, secondary to ulceration of intestine. Indurated bowel palpated through abdominal wall. Laparotomy; death in eight hours.

Mrs. E. D., aged 48. Married, one child, housewife. Still menstruating, never robust, but always well until one year ago. Began to have some pain in abdomen. Pain at first not constant; abdomen always sensitive, so that weight of hand accidentally resting on it as she lay in bed was painful. Not much appetite. Fever for three months with pretty constant diarrhea. Large liquid stools. Anorexia. Lately very profuse sweating. Abdomen tense, oval distension. A movable cylindrical mass felt in right iliac fossa. No pulmonary symptoms. Vaginal examination negative. Diagnosis, tuberculosis of bowel with peritonitis. Operation. Several areas of cylindrical induration of bowel discovered, making resection impossible. Pelvic viscera and entire parietal and visceral peritoneum covered with recent tubercles. Wound closed. Patient never rallied. Death in six hours.

Case 7.—Secondary to tubercular pleurisy, adhesive form. Laparotomy. Death in three days.

J. H., saloonkeeper, aged 37. Brother died of phthisis. Always well until two years ago; had grippe. Pleurisy with exudation, relieved by repeated aspiration. Final obliteration of pleural sac. Abdominal distension gradually growing worse for six months. Slight fever, emaciation, obstinate constipation. Physical examination shows dulness over the base of the right lung posteriorly, due to the greatly thickened pleura. Breath sounds very distant. The abdomen distended, irregular areas of dulness in the midst of tympanitic resonance. Diagnosis, tubercular peritonitis with sacculation. Operation. All viscera matted together. A few small pockets of fluid are broken up; possibly eight ounces of turbid liquid escaped. Wound closed. Death on the third day.

Case 8.—Pain in abdomen. No ascites, no fever.

Child, aged 11. Family history good. No previous illness. Sick four months. Characteristic distension of abdomen. Tenderness on pressure slight. Principal pain comes on after eating so that the boy fears to take food. Steady emaciation. No fever. Bowels constipated. In right iliac fossa a mass can be felt as though made up of adherent omentum; this is not particularly tender. Owing to prominence of gastric symptoms, test meal was given. Analysis showed normal condition of gastric juice. Treatment, rest in bed. Forced feeding. Still under observation.

DISCUSSION.

DR. E. J. BROWN, Decatur, Ill.—Dr. Fenger, several years ago, advised against operation in these cases, showing that the mortality with the so-called medical treatment was less than with the surgical treatment. I think it is very discreditable to the profession to give a bad prognosis in tuberculous peritonitis. I have seen three cases, in which the surgeon who was called in consultation advised operation, all improve without operation.

DR. JAMES TYSON, Philadelphia—As a physician my experience with tuberculous peritonitis has not been large, but so far as it has gone I have about concluded that to treat it medically is to temporize; in other words, that there is but one treatment that is likely to lead to satisfactory re ults, and that is surgical.

TUBERCULOSIS IN THE NEGRO.*

SEALE HARRIS, M.D.

Health Officer of Bullock County from 1895 to 1903; President of the Southeastern Alabama Medical League; Councilor of the Alabama State Medical Association.

UNION SPRINGS, ALA.

Tuberculosis was a rare disease among the slaves in the southern states, yet, after a little more than a quarter of a century, it causes more deaths among the emancipated negroes than all the other infectious diseases. The negro death rate from tuberculosis is more than three times that of the whites from the same disease.

These statements, as startling to some as they are true, announce the motive which induced me to select for my theme on this occasion, "Tuberculosis in the Negro"; and if I can be the means of inciting any of you to consider the causes of this enormous mortality from that disease in the negro race and the measures to be taken for their relief, the objects of this paper will have been attained.

From the best information which I can gather, tuberculosis is unknown among the savage tribes in the interior of Africa. It is also unquestionably true that the negroes along the west coast of Africa were not affected by tuberculosis until the infection was carried there by the slave traders and colonists. However, since their exposure to the infection, the negroes in their native clime are not only more susceptible to tuberculosis than the white colonists who reside there, but the disease is more fatal among them. This is shown by the following table (Dr. Rudolph Matas, "The Surgical Peculiarities of the Negro"), which gives the mortality from tuberculosis in the English colonies for the negroes and whites on a basis of each 1,000 deaths:

	English.	Negroes.
Jamaica	7.5	10.3
Dominica	8.3	16.8
Guiana	6.4	17.9
Ceylon	4.9	10.5
Gibraltar	5.3	43.0

Tuberculosis was so rare among the slaves in the southern states that some physicians contended that the negro was immune to tuberculosis. I have heard large slave owners, and several physicians who had large practices among the slaves in Georgia and Alabama, say that they never knew of a case of consumption among the negroes prior to the war. The disease was so rare that in 1830 a Cincinnati physician reported a case of a negro with "undoubted consumption," in which the autopsy showed "unmistakable evidences of the disease." There were no doubt a few cases among the slaves, but the disease was rare and confined almost entirely to the slaves in the cities, where they were overcrowded and the sanitary conditions were bad. The fact that there were so few cases of tuberculosis among the negroes while they were slaves was a great triumph of intelligent, though enforced, hygiene, and it also proves that tuberculosis is a preventable disease, because prior to the war it was not of infrequent occurrence among the whites of the South. That consumption is almost a scourge to the emancipated negro we all know, and the only reason why it was not so with the slaves was that their habits and sanitary surroundings were better than those of many of their masters.

Because of their indolence and improvidence, I am sure that the majority of negroes in the South do not get a sufficient amount of the proper nourishing food and the other necessities of life on which to maintain health and vitality up to the normal, and such lack of nutrition, added to the worst possible ignorance and carelessness pertaining to personal hygiene, renders his tissues less resistant to bacterial infection of all kinds. In other words, it makes the tissues of the negro a suitable pabulum or soil for the invasion and propagation of the bacillus of tuberculosis. We also know that unless the tuberculous subject is well nourished he has but little hopes of recovery, and I am sure that one of the reasons why there are so few recoveries from tuberculosis in the negro race is that, as a rule, they are not provided with a sufficient quantity of palatable and nutritious food.

The following statistics of Charleston, S. C., which have been accurately kept for many years, show the increase in tuberculosis among the negroes since their emancipation: In 1860 the negro death rate was the same as for the whites, i. e., 12.00 per 1,000. The last census gives the white death rate in that city as 21.4, and the negro death rate of 43.1 per 1,000 of population. The deaths from "consumption," calculated at ten-year intervals, were in 1865, whites 57, negroes 74; 1875, whites, 54, negroes, 132; 1885, whites 57, negroes 209; and in 1895, whites 39, negroes 194. Estimated population in 1895 was, whites, 28,870; negroes, 36,295.

The census returns for the year 1900 show, in the "registration area," in which the statistics may be regarded as fairly accurate, that for every 100,000 of population there died from "consumption" 126.5 native whites and 485.0 of negroes.

I regret that I am unable to give any statistics regarding the mortality from tuberculosis in Alabama and the other southern states. I studied the census returns carefully and found but little that I thought would be of interest or value. The following letter came to my relief, and caused me to destroy most of the data which I had compiled from the census report, and I quote from it to show the fallacy of deductions based on mortality statistics of the United States Census Report, except those for the "registration area":

CENSUS OFFICE, WASHINGTON, D. C., Sept. 20, 1902.

Dr. Seale Harris, Union Springs, Ala.

Dear Sir:—I regret to state that this office can not furnish you any data that are of any value concerning either the

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

general death-rate of the white and colored in the United States as a whole, the southern states, or for South Carolina and Alabama individually, or the mortality of these classes from tuberculosis.

The return of deaths in all of the southern states and in most of the other states was secured by inquiry of the enumerators, and falls very far short of being complete. In fact, the return is absolutely worthless for the purpose of computing death rates and any conclusions based on them would be erroneous. It is only in those states and cities that have efficient systems of registering deaths that we are able to secure anything like a correct return of the deaths that actually occur which can be utilized for determining the death rates. Unfortunately, there are no southern states, and very few cities which have a complete system of registration, and prior to 1890 this source of information was not utilized in any way in census statistics. Very respectfully,

W. A. King, Chief Statistician.

The statistics for some of the southern cities are regarded as being as accurate as those for the registration area, and below I give reports of five representative southern cities:

Rates per 1,000 of Population.

	All Causes.				Tubercular Diseases.			
	1890.		1900.		1890.		1900.	
	Wh.	N.	Wh.	N.	Wh.	N.	Wh.	N.

Mobile, Ala.	21.5	34.5	21.0	32.5	3.04	6.08	3.08	6.09
Charleston, S. C.	21.4	42.2	21.4	43.1	3.55	6.86	1.65	6.21
Savannah, Ga.	24.7	37.8	22.6	42.2	3.71	5.44	2.64	4.91
Richmond, Va.	22.3	37.6	18.1	32.8	2.30	4.11	2.05	3.94

The statistics which I have collected for Union Springs, with an equal population of whites and negroes, and which I think are reliable, show that in the past eight years there have died from tuberculosis fourteen whites and thirty-nine blacks; and of the considerable number of negro deaths reported with the cause of death unknown, I am sure that several died of tuberculosis. I do not know of any other statistics of any value for the small towns or rural districts of the South, for the reasons that the majority of deaths occur without the attendance of a physician, and are reported by midwives and undertakers, who know nothing of the causes of death.

The great prevalence of tuberculosis is not so much due to any inherent tendency to the disease as to their habits and environments, which render their tissues less resistant to the tubercle bacilli, and for the same reasons they fall easy victims to its ravages. However, it is no doubt true that there is a less development of lung tissue and the accessory muscles of respiration among the negroes than for the whites. Dr. McDowell, a surgeon in the United States Army, made frequent autopsies on white and colored troops during the Civil War, from 1861 to 1865. He found that their chest measurements were full (up to the army standard), but their lungs were always lighter and smaller than those contained in the same sized chest among the white troops. The statistics of Otis and Woodward for the same period are interesting. They found a less lung capacity and smaller brain for the negro troops than for the whites. They also found that of whites who contracted tuberculosis during the war, one out of two and one-half died, while of negroes twelve out of thirteen died. Dr. Russell, another army surgeon, states that the average weight of the negro was four ounces less than that of the white.

F. L. Hoffman[1] gives the following interesting table, which he compiled from the report of the Provost-General (Vol. I), and the reports of the Surgeon-General, U. S. A., 1893-94-95, which shows the difference in chest expansion of the slaves who entered the army, and of the emancipated negro of thirty years later:

Comparative Chest Mobility of U. S. Recruits, 1861-65 and 1892-94:

Age Periods.	U. S. Army, 1861-65. White.	U. S. Army, 1861-65. Colored.	U. S. Army, 1892-94. White.	U. S. Army, 1892-94. Colored.
Under 20 years	3.26	3.17*	2.82	2.56*
20 to 24 years	3.25	3.28†	2.86	2.52*
25 to 29 years	3.22	3.25†	2.93	2.62*
30 to 34 years	3.22	3.19*	2.96	2.64*
35 to 39 years	3.26	3.18*	2.94	2.57*
40 to 49 years	3.18	3.34†	2.84	2.52*
All ages	3.24	3.23*	2.93	2.58*

* Excess in favor of white. † Excess in favor of colored.

This table clearly proves that there has been a diminution in the chest expansion of the negro since his release from slavery.

Gould has proven that the average lung capacity of the negro is considerably less than that of the white. Thus, for the average height of 5 feet 8 inches, the pulmonary capacity was for the whites 188.5 cubic inches, for the negro, 167.5 cubic inches—giving a mean difference in favor of the whites of 15.0 cubic inches. The pulmonary capacity of the average chest measuring thirty-six inches in circumference was for the whites 186.5, for the negro, 170.5—thus showing a mean difference of 16 cubic inches in favor of the whites.[2] Dr. R. M. Cunningham[3] has called attention to the "more or less encroachment of the abdominal organs on the thoracic viscera, and for that reason the perpendicular diameter of the chest of the negro is less than that of the same sized white." My observations, carried out on the line of Dr. Cunningham's ideas, from the examination of many healthy chests among the negroes, show that the normal liver dulness on the right side, sometimes extending as high as the fifth rib, and the tympanitic note over the stomach on the left side (Traube's semilunar space) of the negro are higher than that of the whites. I have also noted that Litten's diaphragm phenomenon is less marked in the normal negro than in the white.

Thus all observers agree that there is less development of the lungs of the negro than for the whites, and this physiologic difference no doubt accounts for, in a measure, the inordinate mortality from consumption, pneumonia, and the other pulmonary diseases among the negroes.

Dr. M. L. Perry, pathologist of the State Sanitarium of Georgia, examined the brains of 100 whites and the brains of 100 negroes. He found that the average weight of the brain of the negro was 100 grams, or 3½ ounces less than that of the whites. It is also well known that in the brain of the negro the convolutions are less complex, and the sulci are shallower than that of the Caucasian, which, added to the fact that his brain is smaller, gives the negro considerable less gray matter than for the white. Thus the negro's brain approaches nearer the Simian type than that of the Caucasian, which, according to our ideas of evolution, would place him on a slightly lower scale as a man than his white brother. Probably for this reason they are lacking in the inherent vital nerve forces which in serious illness is sufficient to make them succumb to all diseases, particularly those of a wasting nature like tuberculosis, than does his white brother, who is endowed with a better developed brain structure. I am sure that even under the most favorable circumstances, which I am sorry to say is given to but few of their

1. Race Traits and Tendencies of the American Negro, page 161.

2. Gould, Military Statistics, pp. 480 and 493.

3. The Negro as a Convict, Transactions of the Alabama State Medical Association, 1893, p. 321.

sick, the negro dies more readily from all forms of disease. I have known of many whites who have recovered from consumption when the treatment was begun early, but of the large number of cases which I have treated among the negroes I have seen but a few who showed even temporary improvement, and only one who recovered from the disease.

I would not be understood as meaning that there are any inherent differences in structure of the tissues of the whites and blacks—only a difference in development. The whites have many centuries of enlightenment and civilization under such varied conditions that there has been the psychical and physical development, which fits him to endure the manifold dangers of disease which beset us in our struggle for existence in this complex age, while the negro, a century or two ago, was a savage, perhaps a cannibal, who needed only to provide himself with food, of which nature so lavishes both animal and vegetable in the forest of the tropics of Africa. The heat of that climate made it unnecessary for him to have clothing to protect his body, and with the low altitude and the warm, humid atmosphere, less oxygen was required to maintain body temperature, so there was a corresponding lack of development of the lungs of the native African. This, the hygienic life which he was compelled to lead as a slave, was overcome to a great extent, as is shown by the table compiled by Hoffman, which makes it clear that the chest expansion of the negro was nearly, if not quite, equal to that of the whites in 1861-5, while in 1892-4 it was considerably less. However, the life of a slave did not fit the negro to provide for himself in a climate entirely different in environment to that which his ancestors had lived for ages, and the utter incapacity of the majority of negroes to take care of themselves and families in this climate is the great underlying reason why tuberculosis, which finds its victims in those of a lowered state of vitality, has increased so rapidly, and almost always proves fatal among the members of this unfortunate race.

The filthy habit of spitting shows its highest development among the colored population. Nearly all the men chew tobacco and their women use snuff, and the healthy and the tuberculous alike spit on the floors of many of their homes and churches. The best of their churches are provided with boxes filled with dry sand or sawdust into which they expectorate. The sputum, either on the floors or in the boxes, becomes dry and gets into the dust of the atmosphere, and the bacilli are inhaled in large numbers, and, lodging on lung tissue already weakened from the causes of which I have spoken, they find a favorable soil for their development. When we remember that the consumptive, with a cavity in his lungs, expectorates from 2,500,000,000 to 4,000,000,000 germs in twenty-four hours (Nuttall), and that tuberculosis is so prevalent among the negroes, we can see that this is no chimerical idea that their churches are among the great disseminators of tuberculosis.

Syphilis is not in the least allied to tuberculosis, but it is a well-known fact that syphilitics die from tuberculous diseases. Syphilis is certainly one of the great predisposing causes of tuberculosis, and the great increase in syphilis in the past thirty years has been *pari passu* with that of tuberculosis.

Gonorrhea, on account of their habits of licentiousness, is one of the most frequent diseases among negro men, and every physician who has examined many negro women knows how frequently they are afflicted with "pus tubes." Osler says: "Tuberculous peritonitis in America is a more common disease in the negro than in the white race, and recently collected statistics show that females predominate." Kelly has shown that a very considerable proportion of all cases is secondary to tuberculosis of the fallopian tubes. It is also well known that in man tuberculosis of the seminal vesicles often precedes the development of the disease in the peritoneum. My own observation has been that tuberculous peritonitis is a very much more frequent disease in the negro than in the white race, and that it is several times more frequent in women than in men. For this reason I am inclined to the opinion that gonorrheal salpingitis, prostatitis and seminal vesiculitis prepare the soil for the bacilli of tuberculosis, and from these loci minoris resistentiæ the disease originates and extends to the peritoneum. Therefore, it seems that the gonococcus is the indirect cause of a considerable proportion of negro deaths from tuberculosis.

A great many negro children die from tuberculous peritonitis, which is frequently secondary to the disease in the intestines, and I have no doubt but that the causes of death in many cases reported as gastroenteritis are really enteritis and peritonitis of tuberculous origin.

Nasal catarrhs, tonsillitis, bronchitis and other troubles which are commonly called colds, which are frequent precursors of phthisis pulmonalis, are very prevalent among the negroes, and are rarely ever treated. They are exposed to all kinds of weather, and in winter many of them do not have sufficient clothing to keep the surface of the body warm. Their lack of personal cleanliness, as is demonstrated by their proverbially characteristic odor, which, by the way, is not so noticeable in those who bathe frequently and regularly, prevents the skin from acting freely, therefore, predisposing factors in the development of so much consumption among the negroes, and for the same reasons they are prone to the most virulent types, i. e., acute pneumonia phthisis, phthisis florida or "galloping consumption." Those of us who have treated many cases of tuberculosis among the negroes have seen them die from the acute pneumonic type in a few days or weeks. I am quite sure that many of the deaths reported as due to pneumonia really result from acute pneumonic or bronchopneumonic phthisis.

While the lungs of the negro are the organs most frequently attacked by tuberculosis, he is subject to all its protean forms. Tuberculous pleurisy and meningitis and tuberculous disease of bones and joints are of frequent occurrence among them. Indeed, there is hardly a tuberculous condition which I have seen described that I have not seen in the negro. Lupus seems to be less prevalent among them than any other form of tuberculosis. Lupus, however, seems to be a rare disease in the South.

That tuberculosis is so prevalent among the negroe everyone admits, yet every year goes by and almost nothing is done to stay the hand of this fearful disease, which, with the other diseases to which the emancipated negro is especially prone, threatens the extinction of the negro race and, indeed, greatly endangers the happiness and lives of the whites of the South. This is no new theory with me. Hundreds of other physicians in the South hold to the same opinion, but the whites generally and the negroes do not seem to realize the danger which threatens to almost exterminate the "ward of the nation."

F. L. Hoffman[4] says: "It can be proven at the present time that the colored race is subject to an inordinate

4. Race Traits and Tendencies of the American Negro, p. 82.

mortality from consumption and respiratory diseases, which will menace the very existence of the race in the not far distant future."

Dr. Cunningham says in his paper on the "Negro as Convict": "In conclusion, I will submit that the race problem will be largely settled in the event of public works being established throughout the South, which means ready money for the negro; that means the profitable practice of prostitution; that means gonorrhea and consequent sterility; tuberculosis will do the rest."

Dr. Rudolph Matas,[5] in his splendid and comprehensive paper on "The Surgical Peculiarities of the American Negro," makes the following statement: "Tuberculosis has been called the "great white plague"; but if we look at this matter statistically and through the eyes of all experienced observers we would with greater propriety call it the black plague, as it is unquestionably the dominant cause of the increasing death rate of the negro in this country."

Dr. P. B. Barringer, Chairman of the Faculty of the University of Virginia, in his masterly address before the Montgomery (Ala.) "Race Congress," placed tuberculosis as the principal factor in "that grand but ghastly tragedy—the sacrifice of a race."

I am not an alarmist, and this paper, which calls particular attention to the weak points of the negro, is written for no other purpose than to call attention to the alarming increase of tuberculosis in that race, with the hope that something may be done which will lessen the frightful mortality of the disease in this generally kind-hearted people. The South is doing a noble part by the negro in the line of education, and I am glad that it is so, because without the guiding and protecting hand of a master, the African and his descendants in this climate and this strenuous age can only hope to survive the struggle for an existence through the education of their minds and the training and development of their bodies. If for no other reason than that of self-protection, it is high time that the whites of the South, on whom must fall all the cares and responsibilities of managing the affairs of state for the public good, should take steps to prevent the continued spread of tuberculosis among the negroes. If our cooks, nurses and other servants have the disease there is danger of our families becoming infected. Incidentally, I will mention that I do not believe that tuberculosis is decreasing among the whites of the South, and whatever steps are taken to lessen the prevalence of the disease should apply equally to the whites and negroes.

The methods to pursue in limiting an infectious disease like tuberculosis should be directed toward (*a*) increasing the strength and vitality of the individuals of the race, thereby rendering their tissues an unsuitable soil for the invasion and propagation of the specific germs of the disease, and in (*b*) preventing his exposure to the infective agent, as by the isolation of those already afflicted, and by destroying the organisms causing the disease.

The first proposition presented is the development and upbuilding of the minds, morals and bodies of a "child race," an alien people, placed under conditions and environments which would seem to be unfavorable to the growth and stability of the race, and wholly unlike those under which his ancestors had lived for centuries. In a paper like this I can only discuss this phase of the question briefly, but those who are interested I would strongly urge to read "The Race Tendencies and Traits of the American Negro," by F. L. Hoffman, the able statistician of the Prudential Insurance Co. of America. He has collected and published in this book, at an enormous expenditure of time and energy, the largest and most valuable statistics bearing on all phases of the negro question that I know of in all the literature on the subject. He has applied statistical methods in forming his deductions, and, being a German by birth, and, therefore, free from the so-called race prejudice, his conclusions are of great value, and the facts and figures which he has presented can hardly be questioned.

Much may be done to develop the negro through education applied on the right lines. He has every opportunity in the South that the whites have of obtaining both a common-school and collegiate education, but the moral, physical and hygienic education of the race is almost wholly neglected. By educating the children in these matters they would instruct their parents on the hygiene of their persons and their homes. Their school buildings should be inspected by the health officers in every county and should be kept in a sanitary condition. Regular physical exercises, directed especially toward developing their lungs and the accessory muscles of respiration, should be a part of the daily routine of school duties. The children should be taught the importance of taking frequent and regular baths; that filth means disease, and cleanliness should be required of them. They should be shown the direful effects of immorality on their bodies as well as their souls. A higher standard of morals and education in their ministry and among their teachers would help much in this direction.

Regular daily lessons and talks on practical hygiene should be a part of the curriculum of every school. They should be taught how to live in their homes; that there "cleanliness is next to godliness"; that fresh air and sunlight are among the great boons to humanity, and if they would have health they must have plenty of both in their homes. They should be shown the dangers of overcrowding; that health can not be maintained when more than two or three sleep in the average-sized room; that there is danger in sleeping in the room with any sick person, especially one with a cough. They should be doubly impressed with the danger of spitting on the floors, walls, or any place where the sputum can dry and dust particles get into the atmosphere; that the germs of consumption, which disease, the youngest of them know, is the cause of many deaths of their relatives and friends, is carried through the atmosphere and breathed into their lungs, and that the dried sputum is practically the only source of infection. They should be instructed in the hygienic management of a case of tuberculosis; that there is danger in even a casual association with a consumptive who is careless in his habits of spitting, but that there is little danger of contracting the disease even by close association with a person who has consumption, and who is cleanly in his person and at his home, and who is careful to expectorate into vessels containing dilute solutions of an antiseptic fluid, or into spit cups, which are burned before the sputum has time to dry.

They should also be taught that health and happiness come from regularity of habits and work, diet, recreation and sleep, and that a liberal quantity of all are required to keep in perfect health. Above all, they should be taught the manliness and honor of physical labor, and that their education fits them for their life's work, and not for a life of ease and luxury; that there is as much honor in farming as in teaching or preaching.

5. Transactions of the American Surgical Association, vol. 14, p. 523.

Industrial education is, therefore, a movement capable of doing great good for the race. They should be taught to economize, to save their money and put it in homes and farms. That for their race the dangers of Sodom lie in the towns and cities; that there lurk consumption and death.

These things, and much more, should be taught to the negroes, not only for the sake of right, but to make them stronger physically, so that they may resist the infection of tuberculosis.

The isolation of those infected with tuberculosis would unquestionably limit the disease in a great measure, but the difficulties of enforcing or carrying into effect in any way the isolation of the thousands of indigent tuberculous negroes in every state in the South are so great as to make the suggestion impracticable, though something may be done on that line.

The state could enforce the isolation of the tuberculous patients in their convict camps and penitentiaries, which are often great harbingers of the infection of tuberculosis.

The establishment of sanatoria for the isolation of the tuberculous should receive more attention from philanthropists and the civil authorities. In Massachusetts and other states they have been successfully conducted by the state for several years. Such establishments need not call for expensive buildings, but rather the cottage system, or even on the plans of the plantation quarters for slaves, where the negroes enjoyed such immunity to tuberculosis. They should be located in the country, where the inmates can get plenty of outdoor exercise and when able do farm work, and assist in paying the expenses of such institutions. Very few negroes would be able to pay their expenses at these sanatoria, and they would necessarily have to be charitable institutions, but they could be maintained at a probably less per capita expense than those at the hospitals for the colored insane, and I am sure that the same number of tuberculous negroes are a source of greater danger to their families and to their friends than the same number of their insane, if left in the care of their families. Aside from the isolation feature of sanatorium treatment for consumptives, the hygienic education that it gives to the patient and through him to his relatives and friends will materially aid in protecting many who are exposed to the disease.

There should be several such sanatoria in every state. Even if they should entail a great expense to the state, in the end it will be economy, because in a few years, perhaps a quarter of a century, when tuberculosis will have a chance at the weakened offspring of this and the coming generation of negroes, the havoc will be so great among that race and the danger to the whites so clear that enormous expenditures will have to be made in order to relieve the acuteness of the situation. The state and municipal authorities will spend thousands to prevent an epidemic of smallpox or yellow fever, yet spend almost nothing to prevent the spread of a disease which destroys a hundred times as many of our citizens, and which entails far greater and more prolonged suffering than both of those diseases, besides the direful effects on the offspring of its unfortunate victims.

Unquestionably, tuberculosis should be managed by the health authorities, as are the other infectious diseases. In some of the cities every case of tuberculosis is required to be reported to the health officers, who instruct the patient and his family as to the methods to use to prevent the spread of the disease. The patient is not interfered with in any way, except that he is expected to employ the usual methods of destroying the sputa, and to follow the simple rules of hygiene to protect those with whom he comes in contact. After the removal or death of the patient the patient's room, or house, is disinfected just as for other infectious diseases.

The health officer of every city and county should be required to understand the use of a microscope, and it should be a part of his duty to examine, without charge, every specimen of sputum sent to him. He should also be skilled in physical diagnosis, so that the physician or patient could call him in to clear up the diagnosis in cases of doubt, as is required of him in the other infectious diseases. We all know that tuberculosis is one of the curable diseases if the diagnosis is made early and intelligent treatment is applied. If the public could be educated to call in the health officer in the early stages of tuberculosis and thereby become certain of the diagnosis, not only would many of the patients be saved, but it would aid in lessening the infection, because it would give the health officer the opportunity of instructing the patient and his family on the hygienic measures necessary to prevent the spread of the disease before the home had become infected.

Since the tuberculous patient is dangerous to his friends and the community only from his ejected sputa and directly in proportion to his habits of spitting, the antispitting ordinances, which are already in force in all cities for their public buildings, cars and streets, are doing great good by lessening the chances of breathing the infection from the atmosphere. The states should adopt such ordinances for public buildings of all kinds, including schools, churches and depots. Of course, they would not always be enforced, but a placard announcing the ordinances and stating the reason for their adoption, would call attention to the dangers of spitting, and would aid in molding public opinion against the spitting evil.

Physicians who come in contact with negroes at their homes should, more than any other class of whites, consider it a duty to instruct them in the simple methods of hygiene, particularly when one of the family is afflicted with tuberculosis. The whites should be educated along the same lines, and when the laity, both among the whites and blacks, properly understand the nature of tuberculosis, the life history of its germs, and the methods to employ to prevent its spread, then, and not until then, may we hope to limit the ravages of this disease, the greatest enemy to mankind, and which is the principal agent that threatens the extinction of our "brother in black."

PUBLIC HEALTH POWERS.

WHERE UNDER OUR FORM OF GOVERNMENT DO THEY RESIDE AND HOW SHOULD THEY BE EXERCISED?*

W. H. SANDERS, M.D.
MONTGOMERY, ALA.

The theme for discussion involves the analysis of two questions:

1. Where under our form of government do public health powers reside?

2. How should they be exercised?

In dealing with the first of these questions it becomes necessary to call attention to a few fundamental principles and distinctions that apply to all forms of govern-

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Hygiene and Sanitary Science, and approved for publication by the Executive Committee: Drs. S. Fulton, Seneca Egbert and H. M. Bracken.

ment. Obviously, in all governments power must be lodged somewhere, and on the seat of its lodgement depends the form of government. In a pure democracy all power resides in the people; in an absolute monarchy it resides in the ruler or king. Between these two antipodal forms of government many modifications exist, in which power varying in kind and degree is delegated to the legislative bodies or to officials, civic or military.

Every governmental power, therefore, that is true to the type of government to which it belongs must be derived from the source of power corresponding with that form of government, that is to say, in a democracy every governmental power that can be legitimately exercised must be derived, either directly or indirectly, from the people; while in an absolute monarchy every such power must come in legitimate descent from the king or ruler.

Without delaying time to deal with modifications of these two generic forms of government, it may be said that in any form of government the exercise of a power not clearly derived in accordance with the principle just stated is illegitimate, and therefore revolutionary and dangerous. It follows, therefore, that a public health power in order to be legal must be logically and legitimately derived from the source of power existing in the form of government of which it is a function.

This principle announced, we are now ready to enter on a specific discussion of the first division of the subject, namely, where under our form of government do public health powers reside?

All will concede that after the independence of the states was achieved and before the formation of the Union was accomplished all governmental powers of every kind, including, of course, public health powers, must have resided in the states, or in the people thereof. By the adoption of the federal constitution a national government was created, and to it certain powers were delegated, the powers so delegated being specifically enumerated. Unless it can be pointed out in the constitution that public health powers were surrendered to the national government, they must remain with the states, where they originally belonged. It may be safely asserted that no clause in the constitution can be pointed out that transfers public health powers from the states to the nation, hence the conclusion is irresistible that they still belong to the states. Any one who may take issue with this proposition is challenged to point out in the constitution the clause that overthrows it.

An official who occupies a national position in reference to public health matters was once asked by the writer to point out such a clause, whereon he forthwith cited the power to regulate interstate commerce, conferred on the national government by the constitution. The citation was utterly fatal to his contention.

Before concluding this paper evidence will be furnished from the highest possible source—the Supreme Court of the United States—to prove that while power to regulate interstate commerce does belong to the national government, power to regulate health does not so belong, the two powers being entirely separate and distinct.

Some persons assume that because the power of the national government is supreme in some things it must be so in all things, forgetting that the constitution itself specifically points out the spheres of supremacy of the national government.

"Inclusio unius est exclusio alterius," or the inclusion of one is the exclusion of the other, is a logical law of interpretation that applies to the constitution of the United States as to all other documents.

By applying this law we are able to formulate the definite and incontrovertible proposition, namely, that all powers not specifically or impliedly conferred on the national government are reserved to the states.

Other persons assume that the national government possesses public health powers in and over the states because they think it should be so; that is, they permit their preferences, and not the constitution, to decide the question. Such a position is not entitled to any respect whatever; therefore, time will not be consumed in combating it. The question is, not what should be, but what is.

In this connection it may be well to quote the tenth amendment to the constitution, adopted soon after the ratification of that instrument by the states. It reads as follows:

> The powers not delegated to the United States by the constitution, nor prohibited by it to the states, are reserved to the states, or to the people.

In the face of these plain and strong words, and in the absence of any specific or implied grant of public health power to the national government, the conclusion can not be avoided that such power belongs exclusively to the states.

We now appeal to the highest tribunal in the land, namely, the Supreme Court of the United States, for an interpretation of the constitution on this point.[1]

In Gibbons vs. Ogden, 9th Wheaton, p. 203, Chief Justice Marshall said:

> Inspection laws, quarantine laws, health laws of every description, as well as laws for regulating the internal commerce of a state and those which affect turnpikes, roads, etc., form a portion of that immense mass of legislation which embraces everything within the territory of a state not surrendered to the general government. No direct general power over these subjects is granted to Congress, and consequently they remain subject to state legislation.

In Fertilizing Company vs. Hyde Park, 97 U. S., p. 667, Mr. Justice Swayne said:

> That power (the police power) belonged to the states when the federal constitution was adopted. They did not surrender it, and they all have it now. It extends to the entire property and business within their local jurisdiction.

In Patterson vs. Kentucky, 97 U. S., p. 505, Mr. Justice Harlan said:

> Hence the states may, by police regulations, protect their people against the introduction within their respective limits of infected merchandise. A bale of goods on which duties have or have not been paid, laden with infection, may be seized under health laws, and if it can not be purged of its poison, may be committed to the flames. So may the states by like regulations exclude from their midst not only convicts, paupers, idiots, lunatics and persons likely to become a public charge, but animals having contagious diseases.

Judge McLean, in the Passenger cases, 7 How., p. 400, said:

> In giving the commercial power to Congress the states did not part with that power of self-preservation which must be inherent in every organized community. They may guard against the introduction of anything which may corrupt the morals or endanger the health or lives of their citizens.

In the Passenger cases, 7 How., p. 414, Mr. Justice Swayne said:

> The states of the union may, in the exercise of their police powers, pass quarantine and health laws, interdicting vessels

1. For the extracts from decisions of the Supreme Court introduced the writer is indebted to a masterful argument on "Federal and State Powers as to Quarantine," delivered by Hon. Edgar H. Farrar of New Orleans, at a quarantine convention held in Mobile in February, 1898.

coming from foreign ports, or ports within the United States, from landing passengers and goods, prescribe the places and time for vessels to quarantine, and impose penalties on persons for violating the same; and . . . . such laws, though affecting commerce in its transit, are not regulations of commerce. . . . .

Feb. 25, 1799, Congress passed the following act:

The quarantine and other restraints established by the health laws of any state, respecting any vessel arriving in or bound to any port or district thereof, shall be duly observed by the officers of the customs revenue of the United States, by the masters and crews of the several revenue cutters, and by the military officers commanding any port or station on the sea coast; and all such officers of the United States ,shall faithfully aid in the execution of such quarantine and health laws, according to their respective powers, and within their respective precincts, and as they shall be directed from time to time by the Secretary of the Treasury.

The above extracts from decisions of the Supreme Court of the United States, to which many others of similar tenor might have been added, seem to prove beyond controversy that public health powers belong wholly to the states.

While regarding this principle as thoroughly established, the writer stands on record as having repeatedly expressed the opinion that certain public health powers should be conferred on the general government, the nature and scope of which will be discussed later on in this paper. It would seem that such a grant of power could not be conferred in any other way than by an amendment to the constitution.

We are now prepared to enter on the consideration of the second division of our theme, namely, how shall public health powers be exercised, or, in other words, how shall a public health system suited to our form of government be formulated and executed?

Ranking the public health system of a country as quite equal, if not superior, in importance to that of a judicial or military system, the answer to the question just propounded is worthy of close and critical study.

A categorical statement of the cardinal principles that should be embodied in a public health system for this country may be made as follows:

1. The system should conform closely to the spirit and genius of our government.

2. It should, as far as possible, recognize and respect the principles of local responsibility and of local self-government.

3. It should be co-extensive with the country, and susceptible of immediate enforcement whenever and wherever needed.

4. It should be based on a uniform, coherent and complete organization of the medical profession of the entire country.

5. Boards and bureaus of health should be composed of physicians only, and eligibility for positions in such bodies should depend on membership in the organized medical profession.

6. All medical health officials should be elected by the organized medical profession of the territory or district over which their several jurisdictions extend. All non-medical officials should receive appointment, either directly or indirectly, from the same source.

7. The system should be widely divorced from politics, and should be wholly independent of commercial influence.

8. It should be substantially uniform for municipalities, counties and states.

9. The first function of the system should be advisory; the final one, executive.

10. Economy of administration should be a distinguishing feature of the system.

Should any of these propositions be deemed vulnerable or impracticable, attack on them is invited, as the writer flatters himself they are susceptible of easy and successful defense. Before proceeding further, however, it might not be amiss to briefly comment on some of the propositions.

The first proposition affirms a truth the value of which can not be overestimated. The public health system of a monarchy and that of a democracy must, in some respects, radically differ. In a monarchy, the power needed to operate the system must be drawn from the king or ruler, and all health officials must receive their appointments from, and be responsible to, the same source; while in a democracy the power to operate the system must, in the last analysis, be drawn from the people; and all health officials—medical and non-medical —must, either directly or indirectly, be responsible to the people. That is, the public health systems of these two forms of government must be supplied with vitality and power from two opposite poles or sources.

The same principle applies, *mutatis mutandis,* to all modifications of these two forms of government.

If in the construction of a public health system this principle be violated, either tyranny, on the one hand, or anarchy, on the other, will, sooner or later, terminate the life of a system that fatally transgresses a fundamental law of jurisprudence. We may just as well transplant a tree by placing its branches in the soil and its roots in the air and expect it to grow and flourish and bear fruit as to expect that a public health system constructed to suit a monarchy will permanently live and prosper in this country. Should such a system become a permanent institution in this government it will be because the people have abandoned the faith of their fathers and turned their backs on the blood and treasure spilt and spent in purchasing rights they prized more than life itself.

The second proposition follows naturally and logically on the first, and simply reaffirms the doctrine of local self-government, a doctrine that has been so inbred in the blood and bone of our body politic as to become an integral part of its organic life.

The third proposition will be accepted on its mere statement.

The fourth will also, I hope, as it stands with relation to some of the propositions that follow as premise to corollary.

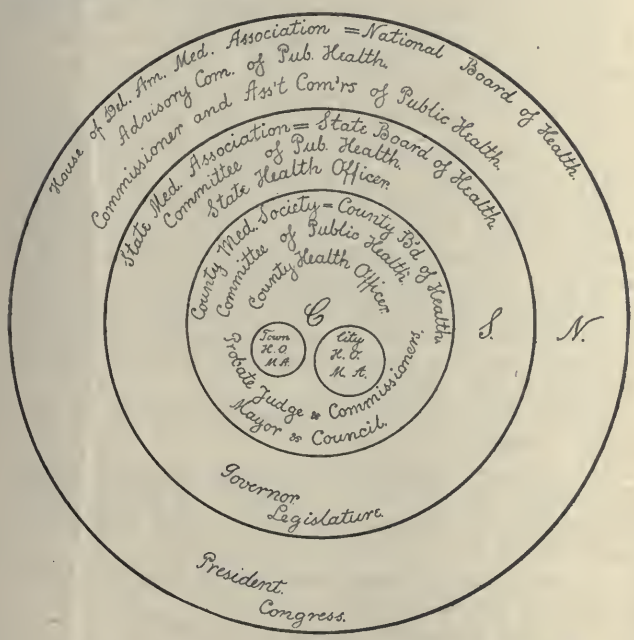
The soundness of the fifth and sixth propositions will not, I presume, be questioned by a body of medical men, but their practicability may be. An argument on this point will be offered a little later.

The seventh, eighth and tenth propositions will, I feel confident, be accepted without argument.

The ninth proposition may need some explanation. This will be given in another and more appropriate connection.

An effort will now be made to apply the principles just enunciated to the hypothetical construction of a public health system for this country, and in so doing use will be made of a diagram, with the hope that thereby the work of construction can be both shortened and rendered more complete and perspicuous. The same unit of construction will be adopted as that generally agreed on for the organization of the medical profession of the country, namely, the county.

The first problem, therefore, to be solved is to formulate a public health system for a county that will be sus-



ceptible of application to all counties, wherever situated. Let the inner or smaller of the three concentric circles in the diagram (in the center of which is the letter C) represent the territory of a county, within which are two smaller circles, one representing an incorporated city, the other, an incorporated town. Within the circle C and within the smaller circles are enumerated, respectively, the authorities that should co-operate in the protection of the health of the people of a county and of all incorporated cities and towns therein.

For the county, it will be seen that these authorities are given as follows:

1. A county medical society, to membership in which all reputable and licensed physicians in the county, including those in incorporated cities and towns, should be eligible.

2. A committee of public health, composed of from five to ten of the most experienced and trustworthy members of the county medical society.

3. A county health officer, with an assistant for each beat, or for two or more beats, according to the size and population of the beats.

4. County authorities, that is, the probate judge and commissioners, or officials corresponding thereto.

For incorporated cities and towns the authorities are indicated on the diagram as follows:

1. City health officer (City H. O.).
2. Town health officer (Town H. O.).
3. Municipal authorities (M. A.).

A little analysis will show the wisdom of an arrangement of authorities such as that proposed, and also of the partition of power that will be made among them.

The organization of a county medical society, composed of the legal and reputable physicians of the county, is a basic principle of construction that must be laid in order to build up a public health system best adapted to our form of government.

Such an organization, aside from being the logical bedrock of the system, would materially promote the advancement of scientific and practical medicine, and by rapidly disseminating among the members the well-digested results of research and experience would render them more skillful and resourceful than they would otherwise be when called on to do battle against disease.

The county medical society should be by law constituted the board of health of the county, and in that capacity should be made the legal adviser of county and municipal authorities on all sanitary and public health questions, subject, however, to such supervision by the state board of health as might be provided for by law. Endowment with such advisory power would naturally stimulate the members of the county board of health to devote more or less special study and attention to sanitary and public health problems, and thus to better equip themselves for the responsible position accorded them.

Further, the meeting-hall of the board would furnish the best possible field for the discussion of all public health questions that might arise, and whatever conclusions might be reached each member would be disposed to accept them in good faith as the judgment of a majority of the members, rendered after full and fair discussion.

Without such a court of last resort differences of opinion as to the best methods of procedure would be continually arising, and in danger of disturbing the harmony, if not of destroying the perpetuity, of the system.

To endow a few physicians of a county with plenary public health powers, without allowing their colleagues any voice whatever in the discussion or direction of public health policies to be pursued under critical conditions, would inevitably lead to discord and disruption and possibly at times to unwise and injudicious action.

In times of peril or pestilence the combined sanitary wisdom of all of the members of the county board of health should be made available, which can not be done in any other way than by making the county medical society the county board of health.

Such a body could, in its regular meetings, discuss broad sanitary questions and indicate general lines of policy to be pursued under varying conditions, but, obviously, a county board of health thus constituted would be too large and unwieldy to meet emergencies, hence the necessity for the second one of the county health powers mentioned above, namely, a committee of public health.

As already stated, such a committee should be composed of from five to ten of the wisest and most experienced members of the county board of health. While large discretionary powers should be delegated to such a committee, it should be required to report its action from time to time to the parent body, when, after thorough review and discussion, such action could be either approved or disapproved. Such a committee would soon become trained in its work and could be very safely trusted to act for the best interests of all concerned.

Next in the list of authorities come the executive officers; that is, a county health officer, with assistants, for the county, and city and town health officers for the incorporated cities and towns.

While the general duties of these officers should be definitely fixed by law, yet in the performance of those duties they should be subject to the guidance and control of the committee of public health.

Lastly, the scope of authority of the county and municipal powers must be fixed, namely, that of the probate judge and commissioners and of the mayor and councilmen. These officials are supposed to be laymen, and, although unacquainted with disease and sanitary science, they must play an important part in executing a public health system suited to a democracy.

They are the legal custodians, respectively, of the treasuries of the counties and of any incorporated cities and towns therein. To them only should belong the

right of appropriating the people's money for public health purposes, except such sums as may have been by law specifically set aside for definite purposes and placed at the disposal of the medical health officials. The county and municipal authorities, being elected by, and, therefore, responsible to, the people, should properly be held accountable for the wise and judicious expenditure of the people's money for public health purposes, as for all other purposes. For violation of this obligation the people could punish said officials by displacing them from office, a check that could not under the proposed system be applied to the medical health officials, they being elected by the organized bodies of the medical profession, and not by the people.

As a public health system can not be executed without money, these county and municipal authorities must, from the treasuries they respectively control, furnish this indispensable lever; hence, as said, they occupy a very important relation with respect to the enforcement of a public health system.

According to the system thus briefly sketched for a county, it will be seen that the advisory and executive health officials, county, city and town, are to be physicians and representatives of the organized medical profession of the county, and that in the application of the teachings of sanitary science to the prevention of diseases they shall avail themselves of the resources of practically all the physicians of the county; that is, the medical health officials would be expected to furnish the expert knowledge necessary to execute a public health system for a county; while the county and municipal authorities would be expected to furnish the money necessary to execute such a system.

When the expenditure of money has been authorized by the county or municipal authorities, as the case may be, to the corresponding medical health officials should be accorded the right of directing the mode of expenditure. If expert knowledge is needed to point out what should be done to protect the public health, the same kind of knowledge is needed to direct how it should be done, else the expenditure of money for such purpose would often be injudicious and wasteful.

In the practical enforcement of the proposed system in a county, including incorporated cities and towns therein, the consecutive steps to be pursued by the coordinate authorities may be stated as follows:

1. The medical health officials of the county, or of the municipality, as the case may be, would advise what should be done.

2. The county and municipal authorities would decide as to whether or not money should be expended.

3. If money is to be expended the medical health officials would supervise the mode of expenditure; that is, the first function of said officials would be advisory, the final one executive.

A little reflection will show the wisdom of such division of authority and of such partition of power.

The members of the medical profession of a county are unquestionably more competent than others to judge of the personal and professional fitness of one another for filling public health positions; hence to no other electors could the selection of expert advisers be so safely and wisely entrusted as to the organized medical profession of the county.

For even stronger reasons the people should exercise the right of selecting the guardians of their treasuries. These guardians, although not physicians, are usually intelligent men, and, therefore, fully capable of deciding on the wisdom or not of expending money for public health purposes, when the reasons therefor are laid before them by physicians in whose knowledge of sanitary affairs and in whose interest in the welfare of the community they repose entire confidence.

Were medical health officials, elected in the way proposed, permitted to expend money for public health purposes (except definite sums set aside for specific uses) without the endorsement of officials elected by, and responsible to, the people, very soon the cry of unwise and lavish expenditures, however unfounded they might be, would overthrow and utterly destroy such a system.

The only way, therefore, of achieving the best results is to so frame a public health system as to place the selection of the medical officials in the hands of those most competent to name them, and at the same time to leave to the people, acting through the custodians of their treasuries, the right to decide whether or not they will provide the means for operating the system.

Objection might be offered to a system that is made dependent on such a contingency, but the answer is easy.

If the people will not provide the means for operating a public health system they will not enact a law making it mandatory on the custodians of their treasuries to provide the means; hence either alternative leads at last to the same test—the will of the people. But if a public health system be provided that works promptly, efficiently and economically, the people will give it their warm support, and such a contingency as that mentioned will not be apt to happen. However, should it occur through antagonism on the part of incumbent county or municipal authorities, popular clamor could soon bring the offending authorities to terms, and at the next election such officials could be retired from office. Any difficulty that might arise in this way would be infinitely less than would result from any other system that can be devised.

We are now prepared to enlarge the system so as to make it comprehend a state.

Let the next larger circle in the diagram, marked S, represent the territory of a state. In that circle are enumerated the powers that should enact and enforce public health laws for the state, to-wit:

1. A state medical association, which should be by law constituted the state board of health.

2. A state committee of public health, composed of ten or more members elected by the state board of health.

3. A state health officer, elected by the state board of health.

4. The governor, as the state executive officer.

5. The legislature, as the law-making power.

The arguments advanced in support of a similar division of public health authorities for a county apply with even more force to the above division of state authorities, and, therefore, need not be repeated here in detail. Some explanation, however, may not be out of place.

The state medical association, hereafter to be called the state board of health, should consist of an organic union of the county boards of health; that is, membership in a county board of health should, *ipso facto,* carry with it membership in the state board of health, conferring the right to attend all meetings, to introduce new measures, to participate in discussions, etc. The voting privilege, however, should be so regulated as to give to each county board of health its due share of strength.

A state board of health thus organized would furnish the medical men of the state a forum for the discussion of public health questions and a tribunal for their set-

tlement—so far as they are concerned—that would tend more than all else to cement the profession together, and to promote that harmony and unity of action without which a thoroughly efficient public health system suited to our form of government can not be maintained.

A state board of health organized as indicated above would for a stronger reason than that applied to a county board be too large and unwieldy to act quickly, or to meet sudden demands, hence the absolute necessity for the existence of the two next authorities mentioned above, namely, an advisory committee of public health and a state health officer. Both of these should be elected by, should act for, and should be responsible to, the parent body—the state board of health.

The state health officer should be clothed with executive authority, but should receive counsel and help from the advisory committee whenever he applies for it, or whenever the committee chooses to give it to him.

The relations between the several state officials should correspond with those outlined for county officials; that is, the function of the medical health officials should be to furnish the advisory and executive skill necessary to enforce a public health system, and that of the governor should be to authorize the expenditure of money for such enforcement, whenever in his judgment the facts represented and the recommendations submitted seem to justify such expenditure.

The function of the legislative authority should, of course, be to enact a code of sanitary laws for the state, in doing which it should freely avail itself of counsel from the state board of health.

Lastly, it remains to see how naturally and logically the system applied to counties and states can be applied to the nation, and made to comprehend certain well-defined public health powers.

Let the largest of the three circles in the diagram, marked N, represent the territory of the nation. Within that circle the following arrangement of health powers is proposed:

1. The House of Delegates of the American Medical Association as a national board of health, to which the health officer of each state should be one of the annual delegates from his state.

2. A commissioner of public health and two or more assistant commissioners, elected by the House of Delegates.

3. An advisory committee of public health consisting of the health officers of the several states.

4. The president, as a national executive officer.

5. Congress, as the national legislative power.

In order to determine what public health powers should be conferred on the national authorities just enumerated, let us assume that every incorporated city and town in the United States does all it should do for the protection of the health of its people; that every county in the United States likewise does all it should do; and, finally, that every state does all it should do, obviously, what remains undone, and what could be better done by all the states working together than by each state working separately, will then become clearly apparent.

Public health powers falling in either one of these categories should be delegated to the national authorities. A little analysis will show what these powers are.

In the first category, or what would remain wholly unprovided for, one function only can be mentioned. That function would be:

To provide an appellate tribunal for the adjudication of any conflicts that might arise between state boards.

In the second category, or what could be better done by all the states working together than by each state working separately, several functions may be mentioned:

1. To adjust the public health relations of this country with foreign countries, under which head would fall the ascertainment of the health conditions prevailing in said countries, maritime quarantine and disinfection, and the examination of immigrants to ascertain their fitness for admission.

2. To supervise interstate quarantine.

3. To determine what infectious and contagious diseases should be controlled by law, and to fix the periods of incubation of such diseases, thus establishing uniformity in these matters among the states.

4. To establish uniform tables of nosology, and to regulate the forms according to which vital and mortuary statistics should be collected by the states.

5. To provide for the inspection of foods and drugs.

6. To exercise supervision over the pollution of streams flowing from one state into another state.

7. To adopt uniform rules governing the transportation of the bodies of deceased persons from one state to another state.

8. To establish on a broad scale a laboratory for the study of the causation, course, pathology and prevention of diseases.

Under such grants of power the national officials should exercise their authority according to the same principle as that laid down for county and state officials; that is, the medical officials elected by the American Medical Association would furnish the expert knowledge and executive supervision necessary for national public health purposes, and the officials elected by the people—the president and Congress—would authorize the expenditure of money for such purposes.

Objection might be alleged against this principle of procedure on the ground that the time consumed for interviews and correspondence between the medical officials, on the one hand, and the corresponding municipal, county, state and national authorities, on the other, before action could be taken, would render the system inadequate for meeting emergencies. Such, however, need not be the case.

A city or county health officer could communicate very quickly with the officials whose coöperation would be needed; a state health officer would be required to consult the governor only, and the national commissioner, the president. Beside, great and pressing emergencies are not very frequent, and in the event of their occurrence provision could be made for permitting medical officials to incur necessary expense in meeting them until such time as all formalities could be complied with.

The coöperation among officials, from a municipality up to the nation, which the system demands, would very soon establish such mutual confidence as to guarantee the utmost harmony on all occasions.

SUMMARY.

The views expressed in this paper may be briefly summarized as follows:

1. Public health powers reside in the states.

2. Counties and municipalities derive all public health powers they exercise from their respective states, and, therefore, are subject to supervision, and, in the last analysis, to absolute control by said states.

3. For the common good, certain public health powers, already enumerated, should be conceded by the states to the nation, provided that the states are allowed

representation in selecting the executive officer who is to exercise these powers, and also representation on the advisory committee for such officer.

4. The selection of all advisory and executive health officials—county, state and national—should be delegated to the organized medical profession of these divisions of government, respectively.

5. Municipal, county, state and national officials, who have been elected by the people, respectively, must control the expenditure of money for public health purposes, except such sums as have been legally appropriated for specific purposes and placed at the disposal of the medical officials.

6. Each division of government, that is, each municipality, county, state and the nation, should provide the funds for executing public health measures ordered by its officials.

By agreement, however, the nation, a state and a county, or municipality, might concentrate their skill and money on any point at which a great menace to the public health exists.

Thus might be formulated and operated a homogeneous, logical and coherent public health system for this country—one whose foundations would be deeply laid in the soil of every county of the United States, whose superstructure would embrace the harmonious systems of all the states, and whose dome would culminate in a crown of conceded and beneficent national authority.

Think of the possibilities of such a system! Aside from securing the removal of unsanitary conditions, the collection of vital and mortuary statistics, the prevention or suppression of outbreaks of infectious diseases, reports on the topography and climatology of every county in the United States, the system could provide for a close and critical study of the domestic, sanitary, industrial, educational and racial conditions existing in every precinct—yea, every household—of the country.

From such data, the statistologist, demographist and sanitarian could evolve truths and principles easily susceptible of being applied to the elevation of the material, physical, mental and moral welfare of the people. Indeed, no better force than the public health officials of a county under the proposed system could be provided for taking the census at the decade periods, they being better acquainted with the people and with existing conditions than any appointees that could be named.

It goes without saying that the medical men of the counties, of the states and of the nation, true to the traditions of the profession, would offer to contribute, "without money and without price," their advisory skill toward the building up of such a system. For the executive health officials only, a large part or all of whose time would be occupied, need remuneration be provided. This should be done by the civil divisions corresponding with their respective jurisdictions.

In view of the "eternal fitness of things" and of the immense, valuable and unrequited services that would be rendered by the great body of the profession in executing such a system, the demand that boards and bureaus of health should consist of medical men only would certainly be deemed both modest and just.

That the proposed system can be built up does not admit of a doubt. If the medical men in every state will resolve that it shall be done, and will then proceed to educate the people in the merits of the system, the end will unquestionably be achieved.

DISCUSSION.

DR. H. A. MOODY, Mobile, Ala.—Every citizen likes to feel that whatever may be the governmental arrangements above him he has some means of controlling them, some way of correcting errors and some way of punishing any faults or acts on the part of the officers in charge, should they be contrary to the laws of the country or to the public good. It seems to me that any system which controls the health of a city or a state or a nation ought to be controlled by the citizens of that city, state or nation, and not by any one individual. I am very glad to be able to say that to-day we are under the charge, so to speak, of a gentleman against whom no one can say a word. He is a good man and a good officer, and everybody likes him; so no one can attribute to him, personally, any criticism we may make of the system itself. But we must look to the future as well as the present, and the day may come when we should regret very much that it is impossible for us to change a health officer located in any city or state, no matter how obnoxious he may be, or however he may neglect his duty. Here will be a man in control of our health affairs who is entirely unsatisfactory to us in every way, and yet we will not be able to help ourselves. I say, I am glad to refer to this matter now when conditions are so satisfactory, in order to call attention to our plight if at any time conditions should change for the worse.

A few days ago I met a gentleman from one of the Gulf states, who expressed himself as satisfied with the turning over of quarantine matters to the Marine-Hospital Service. I asked him how he would like to have foreign officers in control of the police of his state. "Oh," he said, "the doctor has appointed all of our old officers, and so it is all right." That is the way it is. If they will appoint officers who are familiar with and satisfactory to the people, and who know all the requirements of the neighborhood, it is all right. But a day may come when some one else will be in charge, and he may appoint officials who are obnoxious to the people, so much so that it may almost raise a riot in some of our states if they are placed under the control of such an agent.

So I think it not only desirable but necessary for this Association to study the subject and see if we can not have it arranged on a republican basis, and not on the basis of a dictatorship, as seems to be the case at present.

I am not sufficiently informed in quarantine matters to discuss other points raised by the paper and which struck me very forcibly; but, like every other American citizen, I want to have a voice in the appointment of the officers over me. At present I have no voice whatever, and it is only because the gentleman in charge is so acceptable personally, and so thoroughly in sympathy with us, that the system is satisfactory; but when the satisfactoriness of any system depends on the personality of the officer at the head of it, it is not a good system to live under.

DR. R. D. MURRAY, Key West, Fla.—I do not speak as a government officer, but as a "locked-in" man. I sympathize with those people who do not like to have officials forced on them, but I am sure I never went into a place that I did not leave it full of friends. I do not believe a locally acquainted man is always a proper man to control an epidemic. As to the head of the service being fit or unfit, you must remember that he is under the control of a civil officer of this government, who is appointed by the President and confirmed by the Senate, and you can reach him, if you want to, very readily.

Wherever I have been I am proud to say I have left the places full of friends of Murray. On the whole, I think it is better for a foreigner to come down and help people in distress than for a local man to be placed in charge. The local men, as a rule, have too many animosities, belong to too many churches, or have been black-balled in too many clubs. And you know the women cut a figure, gentlemen, at times.

DR. H. D. HOLTON, Brattleboro, Vt.—We have all given expression, especially in the American Public Health Association, to the necessity for a school for health officers, where all who are called to administer the sanitary affairs of a community could have an especial preparation for such duties. It would seem wiser that the health organizations of the Nation, state or municipality should be under the control of trained sanitarians rather than that of the National, state or local medical organization composed of medical men who have

received little, if any, special sanitary training. At the present time the medical men who have the sanitary affairs of states in their keeping are medical men who have acquired what sanitary knowledge they have since their graduation. The great difference in duties imposed on county officials by the constitutions and laws of the different states would make it impractical to have the sanitary affairs of a county administered by the officers of counties in some of the states.

I am in accord with the gentleman from Florida that better and more satisfactory work is accomplished with less friction by having a general officer outside of a particular locality pay an official visit to that particular bailiwick and direct the work. He is free from the prejudices and the fascinations to which the gentleman alluded, and he can and does do his duty without fear or favor.

Regarding a National health organization having any power in the sanitary work of a state, or any interstate authority, I should say that we all recognize that all power conferred on health officials is a police power. Congress and the National executive have the right to regulate interstate commerce, which is not only the interchange of commodities, but also of personal intercourse of the inhabitants of one state with those of another; therefore, if persons affected with any communicable disease in a given state attempts to exercise that part of interstate commerce which consists in personal business intercourse with persons or the transporting of infected goods into another state, it is clear to my mind that National authority has the right to say on what conditions and under what restrictions these transactions shall be conducted. May I ask the author of the paper in his final summing up to make plain the principle of a National health department which should be organized without this power?

Dr. J. M. Lindsay, Havana, Cuba—I will start out by saying that I have no bouquets to throw, and have no knife up my sleeve for any one. I have been working for six months, leaving Havana for the purpose, to see whether we could not get the same quarantine regulations in all the ports of the Gulf. I first came to the American Public Health Association, and got them to endorse a paper I was taking around on an educational tour of the south. The majority agreed with me. (I found only one or two who refused to sign the paper.) I assert that quarantine should be under only one head, but to-day we have it under two. We have it under the U. S. Public Health and Marine-Hospital Service and we have it under the trust known as the Galveston Conference, which we can not get at to save our lives, though we can get at the Marine-Hospital Service. That is under the government, and they do not dare not to answer any letter we write. If they did, we know how to get an answer—through our senator. I have a friend from my district who can always get my letters answered if I can not. I want to say, however, in this connection, that so far all my communications to the department have been answered.

Now, as to the different states: After leaving Florida we come to Dr. Sander's own state. We find there a peculiar condition. The state has nothing to do with the matter. A board is appointed; composed of physicians? No; part physicians and part commercial men, but controlled and run by two people.

I visited that state and asked them to give us the same quarantine regulations at Mobile that we had at Pensacola, Fla., and at Gulfport, Miss. They said: "It is a bitter pill to swallow. Florida and Mississippi are open, but we are tied down by that Galveston Conference and can not do anything. Beside, we do not know what Dr. Sanders, who has charge of all the counties outside of Mobile, will do." There is your condition in Alabama.

I next came to Louisiana, and I asked them to let me come before them and discuss the matter, so as to get them in line with the U. S. Public Health and Marine-Hospital Service, and give us the same regulations as in Mississippi and Florida. They said they could not call a meeting of the board to hear any such proposition, but at the next meeting, which would be at some time in the near future, or in four or five months, they would take the matter up. While I was in Chicago on business, I received a dispatch that they were going to call a meeting, but I could not get there in time.

One of the things I wanted them to do was to use the Marine-Hospital inspectors in those tropical ports where the United States had placed such officials, and not to appoint a man from Louisiana; because it was really not under the police power, and they had no right to collect $200 to pay these men in foreign ports. They would not agree to that. Then I asked them if they could not call a meeting of that conference and break loose from it, because I believed there was no law giving to Louisiana, Alabama and Texas the right to form a trust. I believe in state rights, but when the states seek to give up those rights to a trust, then I believe we had better go under a trust that we can reach through our senators and representatives, and not a trust that we can not touch at all. I believe to-day, instead of fighting fifteen or twenty years to form a new organization, we had better fall in line with the U. S. Public Health and Marine-Hospital Service and get them, as far as possible, to take charge of the entire matter, give us scientific laws, and not be afraid that the south will not support them, because the south will support any scientific quarantine regulations. They say they can not do anything because the people of the south are not educated on the subject. Well, I find that they are educated, and where they are at all deficient it is the fault of the men who know all about it, but who refuse to go out and explain, but seek, on the other hand, to retard the movement in every way.

We have not had a case of yellow fever in two years; still, this port and those of Alabama and Texas have decided that every piece of baggage, every passenger (I believe they use bichlorid of mercury; which is what we used to do when we were looking for fomites) must be disinfected at the port of departure and again at the port of entry. And they will never assume any of the responsibility, but will always try to put it on some one else.

Some six months ago I happened to be in Nashville, and I said to a friend of mine up there: "Judge, you have been losing golden opportunities in the south because of quarantine regulations. I am trying to get the people to give us better regulations in this regard, so we can get the trade of forty millions of people, and I believe it is time the people of the north took charge down there. These are Gulf ports simply because they happen to be on the Gulf geographically, but as a matter of fact they are the ports of the entire nation, and the forty million people in the north have a right to tell these men that they are entitled to protect themselves so far as their health is concerned, but they have no right to make every ship that comes in pay a bonus to get into American ports." He said: "Well, you are going to try to wake them up?" I said: "Yes, sir; that's what I am going to try to do." He said: "Well, I feel sorry for you." "Why?" "Because they will declare it unconstitutional. We in the south declare everything unconstitutional. We have had the shell long enough, and it is time now to change around, because we want the oyster."

To get into Florida and Mississippi costs nothing. To get into Alabama or Louisiana the ship must be disinfected at its expense. Now, I say that when they tell a ship, "You can not do business in this port unless you contribute so much a month to the pay of our inspectors," they go beyond their police powers and enter the National province. They should not be allowed to take that subsidy from the ships, and the sooner we get a new system the better—not such a one as Dr. Sanders proposes, because I tell you when you go up against that you won't have any regulations at all. I know if I had my choice to go up against the Marine Hospital or that trust, known as the Sanders' trust, I would take my chances with the United States every time.

Dr. W. H. Sanders, Montgomery, Ala.—The gentleman who has just taken his seat has indulged in details and personalities that had no connection whatever with my paper. He has set up his opinion on great constitutional questions against the consecutive opinions pronounced by the Supreme Court of the United States since its foundation by the government down to the present time; he has talked about state

rights and trusts and has connected me with what he calls the "Sanders' Trust." I decline the prominence he gives me as being at the head of a monopoly. I am simply the executive officer of the organized physicians of Alabama, selected by them, and I am removable by them at will.

DR. J. M. LINDSAY—I had reference to this trust which you are trying to form.

DR. SANDERS—I have simply proposed a scheme for forming and conducting a democratic system of public health, not one under a single man or a single corporation. The gentleman speaks of the "Galveston trust." I do not know anything of that, and therefore can say nothing of it. Without going into the details he injected into his remarks, and which have nothing whatever to do with the matter under discussion, I will remind him that the first division of the question under discussion is: Where, under our form of government, do public health powers reside?

I attempted to show, and believe I did show, by decisions of the Supreme Court, that they reside in the state governments and not in the general government.

DR. LINDSAY—Have they the right, under the police power, to place a man outside, as they do, to work in the foreign countries?

DR. SANDERS—By consent of those countries. The general government can not put a man there without consent.

DR. LINDSAY—I mean to hold up ships and make them pay; is that police power?

DR. SANDERS—When a ship arrives at the borders of a state the state can deal with it, under her police powers, as she thinks proper.

DR. LINDSAY—When she gets to that state?

DR. SANDERS—Yes, sir.

DR. LINDSAY—Not before?

DR. SANDERS—No, sir; neither can the general government nor the Marine-Hospital Service acting for it. If Cuba, for instance, allows the general government or the state of Alabama to place representatives in Havana to disinfect ships, it is merely a permission and not a right at all.

Now, Mr. Chairman, many positions have been taken that should be answered. Should all public health powers be concentrated in one service, the Marine-Hospital Service, for instance, then all diagnostic power must be conceded to the same service. The officials of that service must do our diagnosing for us. I undertake to say that within the past few years distinguished representatives of the Marine-Hospital Service have made conspicuous errors in diagnosis. If we surrender the public health power now possessed by the states we must also surrender the right to say whether an infectious disease is present or not. In 1897 a fever began to prevail on the Mississippi coast. A number of medical gentlemen, I among them, went there, and after a prolonged investigation decided the prevailing sickness to be yellow fever. The chief of the Marine-Hospital Service selected an ex-official of his service, one who had served in it a number of years, a Cuban by birth, who had grown up with yellow fever, and had attained sufficient prominence in the profession of this country to be filling the chair of pathology in the University of Pennsylvania (I allude to Dr. Guiteras), and sent him down to the Gulf coast to investigate and report. Dr. Guiteras examined into the disease and declared, despite the opinion already announced, that the disease was not yellow fever. I would have conceded in advance that no better man than Guiteras could have been chosen for the work. On a certain Monday morning the announcement went out unanimously from the medical men on the ground that the disease was yellow fever. Dr. Guiteras arrived the following Wednesday, and on Friday telegraphed the chief of the Marine-Hospital Service: "I have examined 29 cases, 25 are dengue, 4 doubtful." Not very long after that Dr. Guiteras accepted the diagnosis that had been made before he reached the scene.

Since then I have seen other members of the service make mistakes in diagnosis. If you surrender the right to control these matters, I repeat, that you must also surrender the right to say whether any infectious disease exists that needs control. That is a dangerous power to concede.

I can not accept the proposition that it is better to have some one come from a distance to regulate these matters. I have had six years' experience as a public health official in my state, and it has been an active one. I should have said that this scheme I have inadequately explained is based on the public health system that has prevailed in Alabama for twenty-five years. It is no visionary scheme, and can easily be projected into a National bureau. Everything proposed inside of that state line (indicating on the diagram) has been in existence in Alabama for twenty-five years.

DR. LINDSAY—What about Mobile?

DR. SANDERS—About ten years ago a number of the commercial men of Mobile went to the legislature, then in session, and, as a very powerful lobby, secured the passage of a special law creating the Quarantining Board of Mobile Bay, which is out of harmony with our system. It would require considerable detail to explain how this was brought about. We are biding our time, and probably by waiting we will see the true system prevail again at Mobile.

With the exception of the Quarantine Board of Mobile Bay, not a commercial man has served on any Alabama board of health for twenty-five years. The members of such boards are physicians, and in no other way can these matters be taken out of politics. Boards of health should be composed of physicians, and health officials should be selected by the organized physicians of the locality over which such officials are to preside. In Alabama the state or county authorities can decline to act on our advice, but if they do the responsibility rests on them. Our authority is merely advisory in the beginning, but if the state or county authorities authorize the expenditure of money, then our authority becomes executive. That is to say, our authority is at first advisory, but if money be appropriated it becomes executive. We have found the system to work admirably for twenty-five years, and we are anxious to see it propagated to other states, and also projected into a National bureau of public health that will correspond to our democratic form of government, and not with a monarchy.

DR. H. D. HOLTON, Brattleboro, Vt.—You said something about interference with interstate commerce. I don't quite understand that.

DR. SANDERS—If the counties do all they should to protect the health within their borders and the states all they should to protect it within their borders, nothing remains for the Nation to do but regulate interstate and foreign quarantine. That is all that remains undone for the Nation to do. It is constitutional for the National government to aid the states in the enforcement of public health laws. The National Bureau of Public Health that formerly existed was founded on that idea. The National government can aid any city or state in trying to control an epidemic, and can appropriate money for that purpose, and send a representative to aid in the struggle. Suppose an epidemic should appear in this city, and the Nation should send here a representative, a sanitarian fully equipped and competent to aid in dealing with the situation, and authorized to aid financially, do you doubt that the health officer of the city of New Orleans and the health officer of the state of Louisiana would accord to that representative of the Nation due consideration and to his opinions due weight?

DR. HOLTON—Suppose the National health officer insisted on regulating things in his own way, would he have any right to do that?

DR. SANDERS—Under the scheme outlined three officials would be on the ground, the city, the state and the National officials, two of whom would be a majority and decide the policy to be pursued. To give the National representative absolute control would require an amendment to the constitution, and, in my opinion, would be very unwise.

Further, the expenses of a campaign against an outbreak of sickness could be equally divided between the city or county, as the case might be, the state and the National government. That would offer a premium on early and prompt action on the part of the county or city. The local officials would know that

by acting promptly they would get the help of the state and of the Nation, which would stimulate them to promptness of action and not to ignore conditions under the idea that by shutting their eyes to them they could get rid of them.

Dr. Lindsay—Where is that ultimate advisory power? In the American Medical Association?

Dr. Sanders—Yes, sir; the American Medical Association should have advisory power for the Nation, for the President, and for Congress; advisory power in the first instance, and then, by suitable laws, it could be invested with certain executive power. Let the Nation be guided in public health matters by its sanitarians, its physicians. When advice from such a source should be laid fully before the Nation, as is done in the state of Alabama, the Nation could either accept or reject it; but if the Nation should act on such advice, then let the American Medical Association, through a National bureau of commissioners of public health, execute its own advice. That is the policy in Alabama.

Dr. Lindsay—That is democratic?

Dr. Sanders—Yes, sir.

Dr. Lindsay—For the Nation to give over this right to the American Medical Association?

Dr. Sanders—The Nation is competent to delegate authority to the American Medical Association, or to any class of men it chooses. I think that is a fundamental principle which can not be successfully controverted. The Nation is competent to delegate its power to any body of men; and if it chooses to delegate it to men selected by the American Medical Association, who can dispute the right?

Before taking my seat I will say that in 1897 yellow fever prevailed in several places in Alabama before its presence was discovered at Ocean Springs, Miss., its original seat. Since then not a case has occurred in Alabama, although the states alongside, Florida on the one side and Mississippi and Louisiana on the other, were overrun, more or less, with yellow fever in 1898, 1899, and, to some extent, in 1900. Not only so, Alabama protected her people and her commerce at a remarkably small cost. For three years the total expense of conducting the state quarantine in Alabama was in round numbers $20,000, and for two of those years the state was entirely protected. My information is that for the same three years Mississippi expended more than $100,000 and got no protection either year. The other states mentioned doubtless expended large sums for the same years and likewise were overrun with the fever. Is not that simple statement of fact a strong endorsement of the Alabama system?

The United States Public Health and Marine-Hospital Service seems to be gradually but certainly usurping the public health powers of the states, which the Supreme Court has said many times is unconstitutional. In addition to being unconstitutional, I believe such usurpation unwise and impracticable. The officials of that service acquire their positions by undergoing examination, and are not chosen either by the people or by their colleagues of the organized profession, consequently they sustain absolutely no representative relation either to the people or to the profession. The chief of that service, who dictates the public-health policy to be pursued by his service, need not be a member of any local medical organization or of this Association, and therefore is entirely independent of any advice or recommendations that might proceed from this body.

Here are assembled representative medical men from the states, and it seems a fair proposition that they should have a representative commissioner of public health of their own selection, through whom they could advise the Nation on public health questions, and whom they could displace from office on his refusal to obey their recommendations.

Venesection and Saline Infusion in Heatstroke.—It is reported by a contemporary that in two cases of heatstroke in Cincinnati twelve ounces of blood were withdrawn, and replaced by an equal amount of physiologic salt solution, with excellent results. Temperature was reduced, convulsions ceased, and the patients fell into refreshing sleep within an hour.—*Med. Age.*

ONE THOUSAND CASES IN STUDENTS' OUTDOOR OBSTETRIC PRACTICE.

REPORT OF FIRST SERIES IN THE OUTDOOR OBSTETRIC DEPARTMENT OF THE UNIVERSITY COLLEGE OF MEDICINE.

JOHN F. WINN, M.D.

Superintendent and Obstetrician-in-Charge of Obstetric Clinics; Lecturer on Obstetrics in University College of Medicine; Obstetrician to Virginia Hospital.

RICHMOND, VA.

I have the pleasure of submitting my report of the first series of 1,000 cases in the outdoor obstetric department of the University College of Medicine for the period of (nearly) eight years, ending Oct. 23, 1902. To be strictly accurate, a service of seventy-six months is represented, the two stations not being provided with regular attendants during four of the college vacations.

Of course, the average number of patients treated annually increases year by year, as the service becomes better known. As far as I know, this work is the first attempt on the part of any medical school in the southern states to conduct a systematic and regularly organized free service for lying-in women at their own homes. Each office or station is centrally located in a laboring district, and fitted up for the residence of three students who respond to obstetric calls only.

It is befitting to add that the successful results of the undertaking are to be attributed, in a large measure, to the hearty co-operation of the students and to their uniform courtesy and professional dignity in the performance of their duties.

The armamentarium of the attendants at each of these two obstetric stations consists of a leatherette telescope or satchel about twenty-two inches long, ten inches wide and eight inches deep, containing the following:[1]

Three agate wash basins.
Towels.
Green soap.
Hand brushes.
Scissors.
Linen bobbin tape.
Sterile gauze.
Absorbent cotton.
Bichlorid tablets.
Lysol.
Boric acid.
Chloroform.
Ergotol.
Fluid extract ergot.
Croton oil.
Strychnia tablets.
Chloral hydrate solution.
Fountain syringe.
Catheter.
Perineal pads.

SIMPLE TECHNIC.

With the unsanitary environments usually encountered, it must, of course, be remembered that anything approaching a complete aseptic technic is impossible; yet the greater necessity for cleanliness is impressed on the minds of the students, and all attendants constantly endeavor to observe, as rigidly as circumstances will admit, the principles of asepsis in reference to vaginal examinations. In doing this no claim is made for any great array of antiseptic or aseptic paraphernalia. On the contrary, the aim is to reduce everything to the simplest possible system of disinfection and asepsis. While the students are not limited as to the number of vaginal examinations, they are encouraged and advised to practice abdominal palpation in all cases if time permits, not only for verification of diagnosis, but for the purpose of reducing to a minimum the danger of infection by vaginal touch.

---

1. Students provide themselves with hypodermic syringes and clinical thermometers. The satchel is not furnished with forceps or other instruments, for the reason that all operations are performed by me; and if such instruments were so accessible, the temptation to use them in my absence might lead to disastrous results. The absence of instruments from the above list is thus explained. A valuable acquisition to this satchel will be found in the form of a large copper pan, like one I have been using for a long time in my private obstetric bag. Its dimensions will correspond with the inside of the telescope, and it will afford a more capacious and ready sterilizer in these homes, and will also serve a useful purpose when asphyxiated infants need to be placed in hot water.

Before making the antiseptic solutions the basins are prepared as follows: They are thoroughly scrubbed with soap and water. One basin is then made the container for boiling the brushes, scissors and tape. Another serves as a cover while the boiling is going on. Before this is completed the third basin is substituted for the second. When all have been sterilized, one basin is used for the bichlorid, another for lysol solution. The third serves as the wash basin. The hands and forearms of each attendant are scrubbed not less than five minutes with hot water and green soap, the water being changed at least once. After the hands have been immersed in bichlorid solution (1/1000) for five minutes, the inner surface of the patient's thighs and the whole of the external genitalia as far as the introitus vaginæ receive the same soap and hot water scrubbing with a soft brush or a gauze sponge, followed by a bichlorid bath. Over the vulva is now laid a pad of gauze or absorbent cotton wrung out of lysol solution (one teaspoonful to one pint).

The patient having been prepared, the hands are again scrubbed and immersed in bichlorid and, finally, in lysol solution before they are considered ready for vaginal touch. Vaselin is never employed as a lubricant. The examining finger is carried directly from the lysol solution into the vagina. The lysol has always proven to be a most efficient lubricant.

More than ordinary care is observed in the manner of making a vaginal examination. The patient is brought to the edge of the bed in the dorsal posture. All bed covering is turned back by an assistant, the genital organs being thus left in full view. While the knees are held apart by another, the labia are carefully and widely separated by the thumb and forefinger of one hand in such a manner that when the index and middle fingers of the other hand are introduced they come in contact with the walls of the vagina only. Just here I will state that the antepartum vaginal douche has never been used in this service. Observation and experience had convinced me that those cases in private practice which did not receive the douche always had a better puerperium than those which did; hence, without knowing why, and even before Krönig's announcement that there were no pus-producing bacteria in the vagina of a pregnant woman, vaginal douches were deemed unnecessary. The effort is made to keep the hands, and especially the examining hand, sterile, but, as a further safeguard against infection, the rule is to repeat the entire process of hand and genital disinfection in all its details every time a vaginal examination is made.

STATISTICAL SUMMARY.

As regards the statistical part of this report, there have been attended:

White cases	129
Colored cases	871
Total	1,000

Representing:

Full-term deliveries	893
Abortions, immature and premature deliveries	107
Vertex presentations	953
Breech presentations	38
Face presentations	2
Brow presentation	1
Shoulder presentations	6
Prolapsed hand	3
Prolapsed funis	3
Imprisoned placenta (not adherent)	14
Eclampsia	10
Postpartum hemorrhage	6
Placenta previa:	
At twenty-seventh week (marginal)	2
At twenty-eighth week (central)	1
At twenty-eighth week (partial)	3
At thirty-eighth week (marginal)	1
	7
Podalic version by internal method	11
Low forceps	18
Median forceps	4
High forceps with axis-traction (living child)	1
High forceps with axis-traction (asphyxiated child, died in a few hours)	1
High forceps with axis-traction (dead-born child)	2
Intra-uterine tamponade	2
Induction of labor at thirty-sixth week; rachitic pelvis (living child)	1
Curettement for inevitable abortion	5
Curettement for retained membranes	18
Perineorrhaphy	12
Extensive laceration of cervix above vaginal junction	1
Twin births	14
Ophthalmia neonatorum (no prophylactic treatment received)	2
Visits	4,421
Septic cases	4
Deaths from all causes	5

In studying the relation of morbidity and mortality to the number of cases, it must be borne in mind that the patients represented, for the most part, the extremely destitute portion of the white and black population, and, consequently, that the work was prosecuted amidst the most unfavorable and unhygienic surroundings.[2] The questions arise, why do not all of these people suffer from the worst forms of sepsis, and why is the death rate greatly lower than that recorded in private practice, and amid even ideal sanitary environments? I confess my inability to account fully for the immunity which this class of lying-in women possesses.

MORTALITY.

In view of the facts mentioned, it is gratifying to find that, out of the 1,000 cases, there have been but five deaths, and, since this portion of the report is significant and especially important, I have deemed it best to give the details connected with each case.

The first death, that of a colored multipara, occurred Aug. 10, 1898. I did not see this case myself, being engaged with a delivery in my private practice, but from the history given by the third-year student in attendance and confirmed by two of our then recent graduates, Dr. M. E. Nuckols and the late Dr. J. Travis Taylor, who saw the case at my request, the woman had had a postpartum hemorrhage. She had reacted well, however, and was believed to be out of danger; but, on attempting to walk across the room (supposedly for water) while alone for a few moments, she fell on the floor and died instantly. I do not like the term "heart failure," but if such is ever admissible, I think it would be quite appropriate for the cause of death in this case.

The second death resulted from eclampsia. A young colored primipara had traveled eighty miles by rail less than thirty-two hours preceding the outset of labor. This was two weeks before her expected confinement. The attendants at the Seventeenth-street station were summoned a short time before the birth of the child. Five hours after delivery they were called back on account of the first convulsion. I saw the case from this time on.

2. The following, one among many similar instances that might be cited, will serve as an illustration of this point: The patient, a colored v-para, occupied the only bed in a small, dark, ill-smelling room. The day was cold. A small coal fire was in a broken-down grate. Around this fire stood four small children. In this room the whole family lived, cooked and slept. There were just two chairs and one dirty kitchen table in the room. Three plates and two cups and saucers were scattered on this table. On the floor, in one corner of the room, was a washtub half full of dirty soapsuds, left from the washing of clothes the week before, and which emitted a horrible stench. The patient asked for a drink of water, whereupon the oldest girl of the family advanced towards the washtub and, with cup in hand, proceeded to dip from a wooden water bucket which was floating around in the foul-smelling mass of soapsuds. On being reminded of the possible contamination of this drinking water, the patient remarked, "O! that's all right." It is needless to say that some of the neighbors were depended on to furnish hot water for the case in hand. The mattress on which the woman lay was exceedingly dirty. An old quilt, equally as black and greasy, served as a coverlid. This woman was up attending to her household duties at the end of a week, with no ill effects.

Notwithstanding heroic treatment, both sedative and eliminative, and, in addition, the constant services of a trained nurse, the patient died ten hours later.

The third death resulted from general septic peritonitis, supervening on rupture of a gonorrheal pus tube, as revealed by the autopsy. This was a colored primipara with a true conjugate of just three inches. I sent the patient to the Virginia Hospital and effected a delivery with forceps, the labor being too far advanced to render version safe. The child, already weak, died during delivery. The patient did well for four days, when peritonitis developed, ending in death three days later. Being anxious to know the cause of this infection, an autopsy was made, with the assistance of Drs. H. M. Taylor and Virginius Harrison, who happened to be in the hospital at the time, and, instead of finding traumatism of the lower segment of the uterus, as was suspected, we found a ruptured pus tube on the right. Inquiry of the patient's mother brought out the statement that she had been treated for gonorrhea two years before.

The fourth death occurred in a multipara at the eighth month, greatly reduced in flesh and strength by tuberculosis. She lost more than the usual amount of blood at delivery, and, though the uterus responded quickly to friction and ergot, the patient proved to be unequal to the shock of this hemorrhage in her already weakened condition. Despite active treatment for shock, the patient died ten hours later.

The fifth death resulted directly from apoplexy, induced by puerperal convulsions. The history of this case is unique and is worthy of record. A young, robust primipara, eight months pregnant, complained, while seated at the breakfast table, of severe headache, numbness of the left arm and leg and also soreness of the tongue. This was about 7 o'clock. She had walked down a winding stairway to the room below. While eating she had a severe convulsion which lasted several minutes. In a quarter of an hour she had another convulsion, more severe than the one preceding and soon passed into a state of coma. The attendants at the Seventeenth-street station saw her for the first time three hours later. I saw the case a few moments afterward. It was soon noticed that the recurring convulsions were confined entirely to the right side. Venesection, followed by saline transfusion directly into the vein, was resorted to with seeming benefit for a short time. The hot pack was also used to aid elimination, but I wish to emphasize one procedure which was pushed vigorously and which gave promise of good results. I refer to prolonged high irrigation of the colon, carried to the point of inducing a free flow of bile. Not less than thirty gallons of saline solution first, and plain hot water later, were used by the return flow rectal tube. This treatment has been used almost to the exclusion of all other eliminating methods in the Paris Maternity, with the result of reducing the mortality from 27 per cent. to 6 per cent. in comparative series of fifty cases, and I am encouraged to give it a further trial. Of course, this case is not a fair test; neither would I be justified in drawing conclusions from one patient; yet I am inclined to believe that, had there not been this cerebral hemorrhage, the eclamptic symptoms would have been held in abeyance. In reverting to the history of this case the patient unquestionably had convulsions during the night, which were responsible for the hemorrhage in the arm and leg center.

While there have been five deaths, it will be seen that not one of these resulted from outside or preventable infection.

It is equally gratifying to know that there have been only four cases of sepsis, and two of these had been attended by midwives before coming under the care of this service. Of the other two cases, one has already been referred to—the case of ruptured pus tube resulting in general peritonitis and death. The fourth and last case of sepsis was a white multipara who had a most extensive laceration of the cervix, extending above the vaginal junction. A great quantity of blood had been lost and she was in a bad condition to resist infection. She was taken to the Virginia Hospital thirty-six hours after delivery, when the symptoms were strongly suggestive of general peritonitis. A careful examination now revealed the cervical injury. Her condition for several days was critical, owing to the large pelvic abscess, which developed under the right broad ligament. On leaving the hospital at the end of six weeks, an inspection, with the aid of Dr. H. Ward Randolph, resident physician, showed that the vaginal portion of this tear had nearly cicatrized. There was yet some discharge which communicated by a sinus with the abscess. The uterus was firmly fixed and drawn to that side. She was sent home with the promise of operative intervention at a subsequent period.

COMPARATIVE MORTALITY RATES.

I have already emphasized the fact that this service was outdoor work (only seven cases receiving hospital treatment) for the special reason that I wish just here to introduce a comparative study of the mortality statistics of some of the oldest and best known obstetric clinics abroad, in some of which the service is more evenly apportioned between indoor and outdoor cases.

For example: Our own mortality is exactly .005 (one-half of 1 per cent.), while that of the obstetric clinic at Prague is reported to be .0085, the School of Baudelocque at Paris .0066 and the University Frauen Klinik at Berlin .0193. Compared with the Society of the Lying-In Hospital of New York City, whose prestige covers more than 100 years, I find reported for their outdoor department 2,723 labors in one year, with ten deaths, or a mortality rate of nearly .0037.

A MODIFIED CREDE METHOD.

In addition to the precautions taken against infection during the first and second stages of labor already referred to, a very important factor in this reduction of morbidity and mortality is believed to be the scrupulous care bestowed on the genital tract during the third stage of labor, not only in guarding it against the invasion of pathogenic organisms, but also in observing the time for and the manner of delivering the placenta. So thoroughly am I convinced that the hasty or precipitate resort to Credé's method is largely responsible for the incomplete delivery of the placenta and its membranes and for the sepsis frequently dependent thereon that it has been the uniform rule in this service to wait for Nature's signal for expelling the after-birth before adopting any method to excite uterine contraction.

Before describing the procedure observed in this clinic, I wish to say that the placing of one hand over the uterus as a sentinel, immediately after the child is born, must not be confounded with the grasp of the uterus in the Credé method. To be explicit: immediately on the birth of the child, one hand is gently placed over the uterus, especial care being taken neither to make friction nor to excite contractions so long as the uterus remains firm. This hand is regarded as a sentinel for Nature's signal that the placenta is separated, this signal being a slight rising of the fundus while it is yet

firm, giving to the hand the sensation of being pushed up, as pointed out by Pinard and Schroeder some years ago. The discovery made by the foregoing authorities was not generally accepted at first, but is now being recognized. This lifting up of the uterus may occur in much less time than the average—"twenty minutes"—or it may be delayed thirty minutes or longer. As soon as this condition is observed, the uterus is grasped firmly, for the first time, with one or both hands and pressed downward in the axis of the superior strait. If, after waiting three-quarters of an hour, there is still no sign of placental separation, as described above, the typical Credé method is resorted to without further delay.

When it comes to the delivery of the membranes, the practice in this clinic is again a slight divergence from the general custom. Instead of twisting them into a rope, as recommended by many, we have found that the possibility of leaving behind a portion of the membranes is greatly lessened by simply waiting a few minutes to allow them to trail out, provided the grasp on the uterus has been lessened to admit of that normal relaxation which follows uterine contraction. In general terms, all attendants act on the principle that every placenta, at full term, has its own time to separate, and that it is better to wait until that time arrives before resorting to artificial stimulation of the uterus. By the rigid observance of this rule, it has been a rare occurrence in the past few years to have even a "retained" placenta, and, as for an adherent placenta, such a condition has not been met with at all.

Broadly speaking, the students in this clinic are taught to regard the genital tract absolutely as a *noli-me-tangere* after the child is born, and experience has demonstrated the fact that, just in proportion as it is so regarded will the puerperium be marked by fewer deviations from the normal.

CONCLUSIONS.

Among the deductions from this report are believed to be the following:

1. The results in this service are confirmatory of Krönig's statement that the vagina of a pregnant woman is free from pus-producing bacteria.

2. Thorough and continuous disinfection of hands and external genitalia are the chief safeguards against infection.

3. The unhygienic surroundings in the homes of the poorer classes must be considered as minor factors in the causation of sepsis. They become operative only when scrupulous care is not observed with regard to vaginal examinations.

4. Not only is the puerperal morbidity and mortality among outdoor clinics greatly below that in private practice (the mortality rate in this clinic being one-half of 1 per cent.), but it would appear that this class of patients is endowed with powers of resistance not found in the higher walks of life.

5. Nature has her own time for separating and expelling the placenta as indicated by a signal easy of recognition.

6. Any method designed to excite uterine contraction before Nature indicates that the placenta is ready to be cast off must be regarded as precipitate, and not in accord with natural processes.

7. Just in proportion as the genital tract is regarded absolutely as a *noli-me-tangere* after the child is born, will the puerperium be marked by fewer deviations from the normal.

Special Article.

THE PURIFICATION OF WATER SUPPLIES BY SLOW SAND FILTRATION.

I.

GENERAL PRINCIPLES AND METHODS.

During the last fifty years the individual or family water supply has been gradually supplanted by the public water supply in nearly all civilized countries. In the United States the number of waterworks has increased from 83 in 1850 to 598 in 1880 and 3,196 in 1896. This fundamental change in the manner of procuring household drinking water has brought in its train many new problems. In several respects the substitution of public for private control is distinctly in the direction of sanitary betterment. The abandonment of the shallow well, for example, has been of unmixed benefit even in communities of moderate size where pollution of the soil is not extreme. It has been noticed that in a general way the introduction of public water supplies is coincident with a remarkable decline in typhoid fever death-rates (Fig. 1).

Although it is thus true that a public water supply is better than the average private supply, it is evident also that the public supply is not without its own peculiar danger. The peril to the whole community is in a

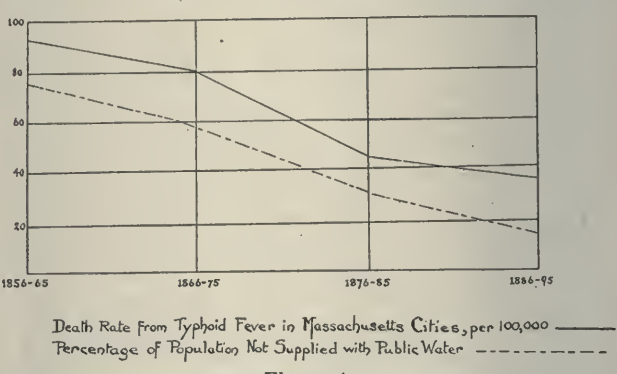


Figure 1.
(From the Twenty-eighth Annual Report of the State Board of Health of Massachusetts, 1896, p. 781.)

sense greatly enhanced by the introduction of a public supply, since if contamination of the general supply ever occurs a much larger number of persons will be infected than under conditions where each family is supplied from an independent source. The proper methods of controlling and safeguarding municipal water sources have become, therefore, a matter of moment to the whole community.

The largest and most satisfactory city water supplies in this country and in Europe are obtained by one of three methods. One of these consists in the impounding or damming of small streams that drain uninhabited or but sparsely inhabited areas. This method usually involves the construction of reservoirs with a large storage capacity, a procedure possessing a notable advantage in that the sanitary quality of water is known to improve during storage. The majority of the satisfactory water supplies of large cities in the United States are of this character, the New York and Boston supplies being well-known examples. This method is applicable especially where the topography of the country is suitable for storage. In a flat region or a densely populated one, supplies of this character are rarely available.

A second method of obtaining a water supply is by utilizing the so-called ground water; that is, water which

has apparently become partially or thoroughly purified by percolation through layers of soil. The "spring" waters and the "deep well" and "artesian" waters belong to this class. Such water is usually clear and palatable, although often "hard"; that is to say, containing in solution certain mineral salts which cause the formation of "boiler scale," lead to an excessive consumption of soap, and are otherwise economically undesirable. On the sanitary side, the quality of ground waters is frequently unexceptionable, although lately they have come to be looked on with less favor than formerly. Several of the largest European city supplies are of ground water origin. The city of Paris, for example, is chiefly supplied with ground water brought from several distant places at great expense, and, although the present supply is somewhat inadequate, a large portion of it is of excellent quality. Many other European cities, such as Vienna, Budapest, Brussels, Leipsic, Cologne, Munich and others are similarly supplied. In the United States no city of the first rank is at present wholly supplied with ground water, although many cities and towns of small size have successfully introduced water of this character. A very large amount of water is demanded by most American municipalities, and the limitations placed by geologic conditions on both the quality and quantity of ground water restrict the use of this source of supply to certain localities.

A third method of obtaining a wholesome water supply consists in treating surface waters, such as the water of rivers or large lakes, by the process of sand filtration. This method of obtaining a good supply is very largely used at the present time in England and on the continent of Europe, especially in Germany and Holland. It is estimated that a population of nearly twenty-five millions in European cities is now furnished with water purified in this way. The list of cities using sand filters includes Berlin, Hamburg, Breslau, London, Amsterdam, Antwerp and St. Petersburg.

In the United States many cities are so situated that neither the first nor the second method of obtaining an ample water-supply is available, and in nearly all instances such cities have up to the present contented themselves with the use of unfiltered surface water from the nearest lake or river. The possible opportunities of contamination to which a surface water in a populous district is exposed are well known and need hardly be considered in detail. It is only too common in many parts of the United States to allow objectionable drainage to pass into a stream from which some town or city derives its water supply. Rivers have been allowed to become open sewers, lakes gigantic cesspools. The danger from this source is generally recognized. In Germany the use of surface waters for public supply without filtration is altogether prohibited. Since it seems to be true that by far the larger number of city dwellers in the United States must continue to depend on some kind of surface water for a supply, it is important to consider what the method of purification of surface water by sand filtration really implies, under what conditions a sand filter may be installed and effectively operated, and what results may be reasonably hoped for in the way of benefit to the public health.

The first sand filter of which any record exists was built in 1829 for the Chelsea Water Company in London. The primary object of this filter was to clarify the water, although the sanitary advantages seem to have been in part recognized. In 1855 the filtration of all the surface waters supplied to London was made compulsory. Soon after this time sand filters were constructed at various places on the continent of Europe, at first from the designs and under the supervision of English engineers. The Berlin filter plant was built in 1856 by an English company and was purchased by the city in 1873. In late years the installation of filters has become very general throughout northern Europe.

The accumulated experience of the last fifty years in the construction and operation of filtration systems has led to the working out of a fairly uniform method of procedure. The unit filter consists of a water-tight masonry tank or reservoir, with a surface area ranging in practice from about one-half of an acre to nearly two acres. On the floor of these reservoirs a series of perforated pipes or loose underdrains is laid, over which are deposited layers of crushed stone and gravel of increasing fineness, and on the gravel is laid finally the bed of sand that constitutes the efficient body of the filter. This layer of sand usually varies from about two feet to four feet in depth. In Germany the law stipulates that the minimum thickness of the sand layer shall not be permitted to fall below twelve inches.

In nearly all instances where filter beds are used it has been found highly advantageous to provide a settling basin through which the raw water shall pass on its way to the filter. Many of the surface waters that are used for public supplies are so turbid that their direct application to the sand bed would cause rapid clogging, and preliminary sedimentation is, hence, most, desirable.

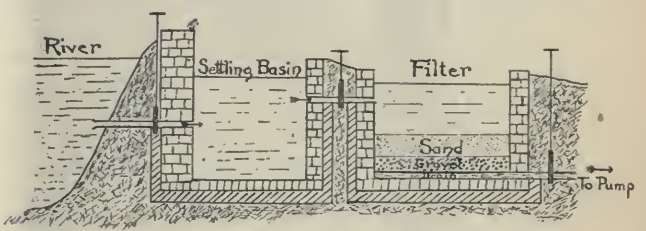

Fig. 2.—Diagram showing general plan of filter plant. (Adopted from Hazen.)

The accompanying diagram (Fig. 2) illustrates the usual relations between the source of the raw water, the sedimentation basin and the filter bed proper.

OPEN AND COVERED FILTER BEDS.

The question of providing covers or roofs for filter beds in cold climates is one that always demands special consideration. The great additional cost of the covers renders their construction inadvisable on economic grounds except where they are absolutely required by the climatic conditions. Under certain circumstances roofing of the filters is imperative. In many parts of Germany it has been found necessary to provide covers for filters which were originally constructed on the open system. The great obstacle to the use of open filters consists in the formation of ice which interferes with the effective operation of the filter, and not only increases the difficulty of cleaning the surface of the sand in winter, but materially lessens the hygienic efficacy of the filter. In Berlin an epidemic of typhoid fever occurring in 1889 was traced to the injurious effect of cold weather on the working of the filter, and this event led to the abandonment of open filters in that city. In the city of Altona, a suburb of Hamburg, a slight epidemic of cholera appeared in the winter of 1893 which was likewise attributed with excellent reason to the disturbance of the filters by ice. The various degrees of difficulty experienced from the formation of ice in those cities possessing an open filter system have led to the estimate that the use of covers is necessary in all locali-

ties where the average January temperature is below 32 F. On this basis, the area in the United States within which covered filters would be necessary lies north of a line passing through Philadelphia, Pittsburg, Cincinnati and St. Louis. The use of covered filters possesses the additional advantage that, owing to the inability of algæ to grow in the dark, the clogging of the filter is diminished and the frequency and expense of cleaning thereby reduced.

RATE OF FILTRATION.

It is evident that the higher the rate of filtration, the smaller is the filtering area needed to supply a given quantity of water. The maintenance of a high rate therefore diminishes proportionately the cost of construction of the filter-plant. In practice it is not found possible to exceed a certain maximum rate without impairing the quality of the filtered water, since if the filter is forced beyond its capacity, efficient purification is not achieved and the aim of the whole system is defeated. The rate that can be successfully used in any given locality depends primarily on the character of the water to be treated. A turbid and polluted water can not be filtered rapidly with as satisfactory results as water from a clearer and purer source. The rate maintained for most European works averages between two and three million gallons daily per acre of filtering surface. The filter beds at Hamburg, where the highly polluted water of the Elbe river is treated, are operated at the rate of about 1,600,000 gallons daily per acre. At Zurich, where a clear and relatively pure lake water is used, the very high rate of over 7,000,000 gallons is successfully maintained. A rate of 3,000,000 to 4,000,000 gallons would probably be a very satisfactory rate for the class of surface waters that would most frequently be dealt with by filtration in this country. In adjusting the rate it is important to maintain a fairly uniform head, since sudden changes are likely to produce disturbances in the upper sand layers, and thereby reduce the efficiency of the filter.

Nearly all the sand filters in actual use are operated on the principle of continuous application of the water, and a body of water of substantially uniform depth is allowed to stand constantly over the surface of the sand. At a few places, however, the system of intermittent application of water is practiced, but it possesses no material advantage over the continuous process and is somewhat more troublesome to operate. The city of Chemnitz, Germany, is one of the best-known instances where intermittent filtration is used for a municipal water supply.

OPERATION OF FILTERS.

In the life of every sand filter the time comes sooner or later when the filter is so clogged that a satisfactory quantity of water no longer passes. The filter must then be cleaned and put again into a condition for effective operation. This is accomplished by draining off the water from the surface of the filter and scraping away a thin layer of sand. The scraping is done by workmen with wide shovels and the sand is usually removed in barrows to some spot where it can be carefully washed and saved for subsequent replacement. A layer varying from .5 of an inch to slightly over one inch is ordinarily removed at a single scraping. The frequency with which scraping has to be practiced depends chiefly on the quality of the water, a turbid water naturally producing clogging more rapidly than water that contains little suspended matter. The rate of filtration and the size of sand grain are also important factors in determining the frequency of scrapings. Twenty-five days is perhaps a fair average of the life of a filter between scrapings. In well-managed works the interval should rarely fall below ten days, and if the preliminary sedimentation is effective, it may well range much higher than this. When the depth of the sand layer has become reduced by successive scrapings to the minimum thickness deemed desirable (never less than 12 inches), the filter is remade, generally with the sand which has been previously removed in scraping, and which after washing is now restored to it. Since a certain proportion of a given filtering area is always out of service while the cleaning process is going on, it is necessary in constructing a filter to plan for a somewhat greater area than would suffice if continuous operation of the whole surface were feasible.

COST OF FILTERS.

The cost of constructing filters depends largely on local conditions. If a very turbid water, for example, is to be treated, an unusually large filtering area must be provided, and the cost of construction is proportionately increased. In Berlin, covered filters of about .6 acre each have been built for approximately $70,000 per acre. One engineering authority estimates that the cost of carefully constructed covered filters in Europe averages about $68,000 per acre of filtering surface. The total cost of the Hamburg plant, one of the most recent of European filtering systems, was nearly $2,280,000. This system includes thirty-four acres of filtering surface, and was designed to supply a population of about 600,000. The data that exist concerning the cost of sand filters in the United States indicate that, owing to the use of more economical designs and to the employment of concrete, the cost of construction should be considerably lower than for European filters. Within the last few years several American filter plants of moderate size and with covered beds have been built at an expense of about $45,000 per acre.

COST OF OPERATION.

The chief sources of outlay for operation are due to the necessity for scraping the sand beds, washing the sand and for supervising the efficiency of the plant. For this latter purpose all well-equipped filter plants include a bacteriologic laboratory, or in some way make provision for testing the quality of the filtered water. The cost of scraping and handling the sand ordinarily ranges from 80 cents to $1.20 per million gallons of filtered water. If the conditions are such as to require special labor for the removal of ice, the total operating expense may be greatly increased. At Lawrence, Mass., where in spite of the cold climate open filters are in use, the cost of removing ice ranged as high in one year as $2.00 per million gallons. Engineering authorities have estimated that, in general, the total cost of filtration, including depreciation and interest on the expense of construction, as well as operating expenses, averages about $7.00 to $9.00 per million gallons of filtered water.

EFFICIENCY OF FILTRATION.

Since the main object of sand filtration is to secure a wholesome water, it is necessary for the engineers in charge of the waterworks to be guided by carefully-drawn regulations concerning maintenance of a safe rate, the quality of the effluent, and other factors of importance. The German Imperial Board of Health has formulated rules requiring that each sand filter shall be tested daily by bacterial methods, that the rate of filtration shall not exceed one hundred mil-

limeters per hour (about 2,600,000 gallons daily per acre), and that the filtered water shall be admitted to the mains only when it contains less than one hundred bacteria per cubic centimeter, the number being determined by a specified method. It has not been found difficult to secure a high bacterial efficiency under these standards. In many cases raw river waters containing several thousands or even tens of thousands of bacteria per c.c. can be made to yield an effluent containing a relatively insignificant number of microbes. At Berlin, for example, during one series of observations the number of bacteria in the water applied to the filters ranged from 4,400 to 7,980, and the effluent during the same period contained from 22 to 52. In general, over 99 per cent. of the bacteria are removed by sand filtration. The experiment of applying particular and easily recognizable kinds of bacteria to the filter beds and testing at frequent intervals for their appearance in the effluent has shown that the actual bacterial efficiency is even greater than the above figures indicate, and that the number of bacteria found in an ordinary effluent does not represent the number actually passing through the filters, but is swollen by a certain proportion of microbes washed out of the underdrains or by accidental contamination during collection. It is a significant fact that in well-conducted filter works, while the number of bacteria in the applied water may vary greatly from hour to hour and from day to day, the number in the effluent remains fairly constant.

A more conclusive measure of efficiency than the percentage of removal of bacteria is afforded by the prevalence of typhoid fever in communities supplied respectively with filtered and unfiltered water. The experience of the city of Hamburg is one of the most convincing instances of this nature. The average death rate from typhoid fever from 1887-1891 was 47.2. A modern sand filter was installed and put in operation in May, 1893, with the result that the typhoid fever death rate for the five years 1894-1898 fell[1] to 7.2. It is true, without exception, that whenever a city has changed from the use of a raw surface water to a sand-filtered water, the typhoid fever death rate has at once responded with a marked and permanent decline.

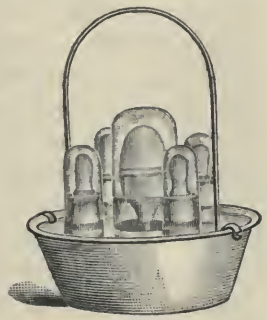
The relative exemption from typhoid fever possessed by cities that are supplied with sand-filtered water as compared with those using raw surface water is shown by a comparison of the typhoid fever death rate in certain European cities using sand filters with the rate in certain American cities, some of which are provided with a surface water deemed to be fairly well guarded and free from the grosser forms of pollution: Berlin, 0.50; London,[2] 1.40; Hamburg, 0.90; Rotterdam, 0.20; Boston, 2,79; New York, 1.81; Baltimore, 4.50; St. Louis, 4.70.

(To be continued.)

1. The cholera year 1892, and the year 1893, in which the filter was not operative during the whole period, are omitted from the comparison.

2. About five-sixths of the total supply is filtered.

Coffee-Drinking.—Notwithstanding the scare advertisements of health substitutes for coffee, says the *American Journal of Pharmacy*, there is no cause for apprehending danger to the race at large from coffee-drinking. After generations of almost universal coffee-drinkers, our own times see men of gigantic intellect in all realms of activity, our athletes are able to make sudden bursts of effort equal to any in history, and our soldiers aquit themselves manfully in fatiguing campaigns in torrid climes. The life-insurance companies, constantly warring against all that lessens longevity or conduces to abnormal organs, nerves and actions, seem content to accept the use of coffee as one of the ordinary elements of every-day life.



New Appliance.

AN OPHTHALMIC TREATMENT OUTFIT.*

WM. CAMPBELL POSEY, M.D.
PHILADELPHIA.

This appliance is presented to the Section with a view to facilitating and further perfecting the details of treatment of ophthalmic cases. It consists of a series of bottles, contained in a nickel-plated caster-like holder, which in its turn rests in an enameled pan. The bottles are five in number; one, with a capacity of four ounces, holds a boracic acid or other mild antiseptic solution for the purpose of flushing the eye; the other four are one-ounce bottles and contain such drugs as may be required. Each bottle is provided with a pipette, which serves as an accurately fitting stopper, and also with a glass cover, to further prevent the entrance of germs or dust into the bottle or dropper.

By this arrangement there is secured for each patient in hospital service a complete set of bottles for his individual

use, thereby avoiding possible infection from other patients or the instillation into his eyes of drugs intended for another. The outfit may be employed in operations and will be found convenient in the treatment of cases in their own homes, either after operations or where there is inflammation requiring protracted treatment and the employment of a number of drugs. The pan is intended to hold ice when ice compresses are to be applied, or as a vessel in which to heat the water, when hot compresses are desired. The pan is attached to the caster-like holder by a double spring, and although the outfit is intended to rest on the table at the bedside, it can be carried about if occasion demands. The various parts of the outfit can be readily sterilized and may be used in successive cases.

Clinical Report.

CASE OF SKIN GRAFTING.

JAMES FREDERIC CLARKE, M.D.
Lecturer on Hygiene, State University of Iowa, Department of Medicine,
FAIRFIELD, IOWA.

A few weeks ago a patient presented with contraction of the upper eyelid from a burn. The cilia was drawn high on the forehead. An incision was made 2 mm. above the cilia, the lid was dissected down and the upper and lower lids stitched together. The exposed surface was at once covered with one piece of skin taken from the forearm of the patient. The piece removed from the forearm was an oval 1¾ by 3 inches in size. This was held in place by 6 or 8 sutures, covered with gutta-percha tissue and a cotton compress. On removing the dressings on the fifth day the skin graft was pink in color and sensitive to the touch. It had a well-established circulation and sensation in this short time. The complete success of the transfer of this large piece of skin was quite a satisfaction, seemingly so much better than sliding skin from the temple, which would have increased the scars.

NEPHROTOXINS.

The existence and experimental production of specific cell poisons, the cytotoxins or cytolysins of which we hear so much nowadays, have been the means of greatly stimulating the interest in cellular reactions. Many enthusiastic investigators believed that in this field would be found the quick solution of some of the obscure problems in the genesis of disease. Of the cytotoxins for the cells of solid organs nephrotoxins, or special poisons for the cells of the kidney, have been studied most extensively. The renal cells seemed to respond readily to normal and to artificially-produced toxins, and the resulting functional and morphologic changes presented such analogy to the changes in some forms of nephritis that it appeared to many as if we had come into possession of the key that would unlock the mysteries connected with the etiology and genesis of nephritis and the accompanying disturbances of the circulatory apparatus, as well as uremia.

It is as yet too early to decide definitely to what extent the new method of investigation will give final solution of these complex problems. The conservative observer might be tempted to say somewhat sneeringly that so far not much else has been accomplished than to substitute new names for the old and that the ultimate mechanism of nephritis is still unknown. A fair consideration of recent work in this field, however, can not but lead to the conviction that actual progress in renal pathology is making as the direct result of the study of nephrotoxins. A brief review of the experimental study of nephrotoxins by Pearce[1] will serve to make this point clear.

It has been claimed by several European investigators that the ligation of one ureter or of the vessels of one kidney leads to degenerative changes in the opposite kidney due to the action of toxic substances which have been called autonephrolysins or autonephrotoxins. Pearce made careful experiments to test this conclusion with the result that no other changes were established in the undisturbed kidney than would follow simple nephrectomy, thus demonstrating that the products of dissolution of one kidney have no direct, specific harmful action on the fellow kidney. Pearce, furthermore, controverts the claim that "isonephrotoxins" are easily obtainable. By isonephrotoxin is meant a poison for the kidneys of animals of the same species as the one furnishing the poisonous serum. Such serum has been claimed to develop after unilateral ligation of the ureter or the renal vessels as well as after repeated injection of, let us say, rabbit's kidney into rabbits. In Pearce's experiments it was found that the injection of pure, untreated, normal rabbit's serum causes as great changes as the injection of supposedly isonephrotoxic serum. Pearce succeeded in producing a strong nephrotoxin by immunization of rabbit's with dog's kidney. In order to eliminate so far as possible the simultaneous production of a toxin for the red corpuscles of the dog (hemolysin) it was necessary to use organs well washed to free them from blood. Now, in previous experiments with heteronephrotoxic serum the action of this hemolysin has not been excluded. The action of the hemolysin consists in laking red blood corpuscles in such numbers as to cause hemoglobinuria, and this is in itself sufficient to cause changes in the kidneys of the animal used. Pearce found that even after the use of washed kidneys for injection there developed hemolytic properties in the serum of the animals injected, but in much less degree than in the animals treated with unwashed organs. Heteronephrotoxic serum thus produced causes albuminuria, cast excretion, degeneration in the epithelium and glomeruli, but no noticeable interstitial changes. Chronic renal lesions could not be established by the repeated injections of toxic serum, and there were no immediate changes in the blood pressure. Pearce also found that hepatotoxic serum, produced by injecting rabbits with dog's washed liver, causes changes in the kidneys of dogs, thus bringing into prominence a correlative action of several kinds of serum which has been noted also by previous observers. In the course of his work he had occasion to note that in dogs spontaneous nephritis is not at all infrequent, and the serum of nephritic dogs is toxic for the renal cells of normal dogs.

We see that the work of Dr. Pearce, to a large extent, consists in disproval of extravagant claims of previous workers and in eliminating manifest sources of error. This somewhat unpleasant task is often necessary in order to clear the field for actual progress. There remain, principally as the result of Pearce's own work, some important well-established facts, namely, that the renal cells of the dog are altered in function and form by the injection of serum of rabbits treated with dog's kidney; that toxic serums are correlative in their action, indicating that various cells are similar in chemical structure, and, finally, that the serum of nephritic dogs is nephrotoxic for normal dogs. The question of the source and nature of this nephrotoxic substance furnishes interesting problems for future work. We believe that the study of somatogenic cytotoxins is on a firmer basis as the result of the investigations of Dr. Pearce, but it is evident that the explanation of chronic nephritis, for instance, is still far off.

MANUAL TRAINING FOR GIRLS.

In an address[1] to the graduating class of Johns Hopkins Hospital Training School for Nurses, Isabel

1. Bulletin of Johns Hopkins Hosp., September, 1903.

Hampton Robb, formerly superintendent of the school, has discussed some of the defects in trained nurses. She insists that "inefficiency, superficiality and lack of thoroughness belong not to the graduate nurse alone, but are the common property of modern woman, and belong to the average American household." Out of 175 applicants for admission to our training school for nurses only forty were considered worthy. The deficiency of women in the practical knowledge of the affairs of the house is strongly emphasized. An effort is now being made in many of the more progressive training schools for nurses, both at home and abroad, to overcome, by means of a preliminary course, this deficiency as regards the care of the household and the properties of food. Desirable as this is, it is only an effort to accomplish for the few what should be a part of the education of every girl in the public schools. No one knows better than the physician how inadequate are the ideas of women in general regarding the proper preparation of foods, and how impossible it is to obtain proper food for the sick in a great many households. Improperly prepared and unwholesome food is a most fruitful cause of disordered digestion, and careful observers have even ascribed much of the use of alcoholics by the poorer classes to this cause.

While there is a tendency to give manual training an important place in the education of boys, is it not possible that manual training for girls is of equal importance? In the case of girls this training would naturally have to do with the subjects which would not only develop manual dexterity, but which would also serve to stimulate intelligent interest in the things with which they would have to deal in the home. Is there any reason why a girl should not be as much instructed and interested in the making of a dress, a stocking or a loaf of bread, as her brother is in the construction of a box or a machine? In this way the use of the needle, the cooking and preparation of foods, cleanliness and the care of the house could be made matters of interest instead of drudgery, and the school girl would introduce the elements of domestic hygiene into many homes into which they could not be forced by health officers and all sorts of legislation.

If such instruction were given to girls in the public schools, it would perhaps help to dispel the idea which has unfortunately become so prominent in the minds of young women that "housework" is mere drudgery and calls for only an inferior degree of intelligence. Anything is worth while which will teach girls that the problems of the home call for the exercise of the highest degrees of intelligence, training and education, and that the pleasures and satisfaction of doing household duties intelligently in the end can not be compared with the routine work of the shop and the factory.

We wish that the excellent address of Mrs. Robb could be read by every one who has to do with the education of girls. Many an intelligent and conscientious mother would find in it ideas and stimulus that would benefit directly the household and all its members, especially the women, and in the end serve to reanimate the interests of woman in her special work.

RECENT WORK ON THE BACTERICIDAL ACTION OF SERUM OF ANIMALS SUSCEPTIBLE TO ANTHRAX.

It is a well-established fact that normal human serum and the serums of many of the lower animals possess *in vitro* strongly bactericidal properties for many pathogenic bacteria, and yet both human beings and animals are often susceptible to infection with the organisms which are killed by their serums in test-tube experiments. As examples of such cases may be mentioned typhoid fever, dysentery and anthrax. One c.c. of normal human serum in a test tube will kill thousands of typhoid bacilli or dysentery bacilli and yet there are times when these organisms gain entrance into the body, multiply and produce their respective disease. Rabbits are very susceptible to infection with anthrax bacilli in spite of the fact that their blood serum is capable of killing thousands of these organisms when added to a small quantity of the serum in a test tube. On the other hand, it has been found that dogs are relatively immune, and chickens are almost absolutely immune from anthrax, though their extravascular blood serums possess no bactericidal properties for *B. anthracis*.

The serum of a rabbit which has died of anthrax has not lost its bacteriolytic serum-complement, and it is still capable of killing anthrax bacilli, showing that the infection can not be explained on the score of a loss of the complement in the serum. It is evident, therefore, that there is here a sharp disagreement between the facts found by test-tube experiments and those observed in the living animal body; this goes to show that the results obtained by test-tube experiments may be very far from representing what takes place in the animal body, because the conditions are so widely different.

Test-tube experiments, however, are at present one of the best means we have for attacking such problems as immunity, and the aim of the experimenter must always be to approach, in the test tube, the conditions found in the animal body. A decided step in this direction was recently taken by Bail and Pettersson[1] in their work on anthrax. Normal rabbit's serum, as indicated above, is strongly bactericidal for *B. anthracis*, when the latter is added to a small quantity of the serum in a test tube. The experimenters mentioned have found that the results are very different if instead of clear serum they had used serum to which had been added finely emulsified fresh organs (such as liver, kidney or muscle) from the rabbit which yielded the serum. Serum thus treated with organ-suspensions is deprived of its germicidal property, even if the tissue cells and fragments are centrifugalized out before the bacteria are added. The addition to the serum of a few drops of extract from these organs, in physiologic salt solu-

1. Centralbl. f. Bakt., 1903, xxxiv, 445.

tion, has a similar effect. It is interesting to note that these extracts in themselves have no bactericidal properties. Heated beef serum and dog's serum which are normally not bactericidal for anthrax bacilli are rendered so by treating them with fresh bloodless organs of rabbits. The normal beef and dog's serum may also be activated by the addition of traces of a rabbit's serum which has been inactivated by the admixture of organ suspensions.

It may be objected that the conditions here were very different from those found in the body because the experimenters were working with dead cells, even if they were removed from the body only two hours previously. It is nevertheless a decided advance toward approximating, in the test tube, the conditions found in the body. We believe that the observations of Bail and Pettersson constitute a step in advance toward the explanation of the apparently paradoxic phenomena noted above in regard to certain infections. These observations show once more the wonderful complexity of the phenomena of infection and immunity.

LEGISLATION AGAINST THE SALE OF COCAIN.

A bill has been introduced in the legislature of Alabama regulating the practice of pharmacists, establishing a state laboratory at the capital where all applicants for license will be examined. A special provision—and this is why we call attention to the matter—throws additional restrictions on the sale of cocain, the use of which has become so great an evil among the negroes of the South. Druggists will be prohibited, if the law is passed, from selling cocain except on the prescription of a physician, and the physician must, if called on, give good reasons for prescribing the drug. While this last measure seems a little extreme, it is possible that there may be physicians who would prescribe dangerous drugs without good reason, simply to meet the appetite of patients, and such may very well come under the provisions of the law.

MASSACHUSETTS "ALLOPATHS."

The Massachusetts Bureau of Labor Statistics has been taking a census of persons employed in "gainful" occupations. Whether or not the majority of physicians are engaged in "gainful" occupations they are included in these statistics. The *Boston Medical and Surgical Journal*,[1] among other comments, has the following:

> The number of physicians and physicians and surgeons who were willing to answer to the nick-name of "allopaths," was 1,432, of whom 56 were females. There were also 385 who answered to the name of "homeopaths," 83 eclectics, 77 specialists, and 2,213 who were not specified. Of the 4,188 persons employed in the profession of medicine, 486 were females.

It may not be altogether amiss to call the attention of the Massachusetts State Medical Society to the fact that while it has 2,607 members, according to our contemporary, there are said to be only 2,290 physicians in the state who are not sectarians, i. e., eclectics, homeopaths or "allopaths." Is not an "allopath" as much a sectarian as a homeopath? Seriously speaking, is it not time that the physician who is not a sectarian disregarded the nicknames given him by others and was satisfied to be just a plain physician? In this case an ignorant census-taker may have classed a physician as an "allopath" in spite of the physician's clear statement of his status, and much to his dismay on seeing the published report, but one such occurrence should put him on his guard. Let it be eternally understood that we are not "allopaths."

1. Sept. 17, 1903.

SAN FRANCISCO'S MAYOR AND BOARD OF HEALTH.

The report of the San Francisco Board of Health to the Hon. E. E. Schmitz, the mayor, is interesting reading. The reporting to the mayor was evidently purely perfunctory, and it seems also from a statement in the *Occidental Medical Times*, in which the report appears, that its publication in regular channels was denied. This is not to be wondered at, considering the fact that it contains the strongest kind of indictment of the honorable official to whom it is made, and that without any circumlocution or evasion whatever. The mayor is practically shown up as a falsifier and his various offenses against good morals and sanitation are thoroughly brought to light in language the reverse of complimentary. It is a curious thing that politicians who are generally supposed to be wary and far-seeing (though this latter is perhaps open to question) deliberately go to work to make history in which they appear in the most unfavorable light.

THE ORIGINATOR OF THE STOMACH TUBE.

We have briefly noticed in our Current Literature Department[1] an article by Friedenwald in the *Johns Hopkins Hospital Bulletin*, calling attention to the fact that the discovery of the stomach tube should be properly credited to one of our early American physicians, Dr. P. S. Physick, and not to Jukes and Bush, the English practitioners, to whom the honor of its invention has been assigned. It appears clear from this publication that Dr. Physick had employed the method for years when he published his first article on the subject in the *Eclectic Repertory*, Vol. III, p. 110, October, 1812, under the title of "An Account of a New Mode of Extracting the Poisonous Substances from the Stomach." In a later issue of the same journal Dr. Physick makes a correction to do justice to Dr. Alexander Monro, Jr., of Edinburgh, to whom he magnanimously surrenders the credit of the invention because the latter had mentioned its possibility in a thesis published in 1797, to which Dr. Physick's attention had been called since the publication of his article. The fact is, however, as shown by the article, Dr. Monro never utilized the suggestion, and Dr. Physick conceived the idea independently and had tubes made for the purpose as early as 1803, and in his lectures to students, as shown by several communications from former students, was in the habit of recommending the method at that early date. In those days the medical and scientific world did not look to America for important inventions, and it was easy for the English inventors to get the honor as against Dr. Physick. Credit was given to the

1. Page 879, abstract 43.

former, though little attention seems to have been paid to the matter. Dr Friedenwald's article does justice to this early American pioneer of medicine.

PROFESSOR SHERRINGTON'S VISIT.

At the opening of the new medical buildings of the University of Toronto on Thursday of this week, the address of the occasion was delivered by Prof. Charles Scott Sherrington of the University College of Liverpool. The new buildings in Toronto, beside being admirably adapted for the teaching of the medical sciences in a modern way, have been especially constructed and outfitted for the prosecution of original research. It is peculiarly fitting, therefore, that the distinguished director of the Thompson Yates Laboratories, who is England's greatest research physiologist, should have been chosen to make the formal address at the opening ceremonies. Modern physiologists are roughly divisible into two groups, one approaching the problems of physiology from the viewpoint of medicine and interesting itself, therefore, chiefly in the physiology of vertebrates; the other, from the viewpoint of general biology, physics and chemistry, more concerned perhaps with the simpler forms of life as met among the invertebrates. Both groups have in them representatives of the highest order of productive scholarship. To the former of the two groups Professor Sherrington belongs, though his researches and his publications show that he is not unsympathetic with the work of members of the other group. Professor Sherrington has enriched knowledge in every field of physiology in which he has worked, but his most striking services perhaps are those he has rendered to the physiology of the nervous system. His studies of the spinal nerves and of the segmental relations and especially his researches into the functions of the cerebrum of the vertebrates which stand nearest to man, have given him a fame that is world wide. We understand that Professor Sherrington is to visit some of the medical centers of the United States before he returns to England. We can assure him of a most cordial welcome in American physiologic laboratories, and we may perhaps hope that when he returns to Liverpool he may favor us with some impressions of American medicine as seen through an English physiologist's eye.

THE EYE IN NEURASTHENIA.

While the eye symptoms of neurasthenia are well known to many neurologists and ophthalmic specialists, it is possible that their true relation to the general condition is often overlooked. This is probably the more likely to be the case when there exists an actual defect of refraction which when detected is credited with the whole trouble. In a recent paper[1] Gradle calls attention to these facts and emphasizes the importance of attention to still other general systemic disorders that may reveal themselves most prominently in symptoms referred to ocular defects or accent such defects when they exist to a slight extent. These symptoms frequently involve more than merely the eyes, headaches, dizziness, etc., and are not uncommon. The most frequent of the underlying conditions he finds is anemia, while a general neurotic tendency, inherited or acquired, unhealthy environment, lack of exercise and other debilitating influences are hardly less important. Intestinal derangements may also play their part, and when any of these conditions coexist with a slight optic error, the unpleasant possibilities of the latter all come to the fore, sometimes to a distressing extent. Even with perfect emmetropia, intense asthenopic distress may result from pronounced anemia or intestinal autointoxication. Gradle deprecates, therefore, the tendency to treat these conditions by ordering weak glasses without due attention to the general condition, which may alone suffice to give relief. While he considers here only cases without muscular insufficiencies and expresses his doubt whether muscular anomalies that can only be demonstrated by suppressing binocular vision by prisms, etc., can cause asthenopia, it is almost impossible to avoid the suggestion that some of the troubles attributed to muscular eye-strain may be also due to such general conditions, associated it may be with latent refractive anomalies, or it may be, with latent muscular weakness, of itself incapable of causing the trouble under normal health conditions. Psychic influences, as Gradle points out, may have like effects, either through over-attention to the eyes or by exaggerating the effects of some slight and transient injury or inflammation. In these cases the hysterical character can be suspected after exclusion of other conditions and the possibility of suggestive therapy is indicated. It may succeed, but many cases are difficult to affect in this way. It is probable that closer attention to the systemic causes of ocular symptoms is needed not only on the part of the general practitioner, but sometimes possibly on the part of the ophthalmologist.

1. Arch. of Ophth., July.

Medical News.

ALABAMA.

Personal.—Dr. Felix A. Gillespie, Hanceville, has been obliged to leave his work and go to Texas on account of his health.

Appropriation for Medical College.—The house of representatives has passed the bill appropriating $5,000 annually for four years to aid in the repairs and extensions of the buildings and the equipment of the medical department of the University of Alabama, Mobile.

Cocain Sale.—In the bill endorsed by the Alabama State Pharmaceutical Association, there are provisions prohibiting druggists from selling cocain except on physician's prescriptions, providing that the physician, if called on, shall show reason for prescribing the drug.

Neckties and Water.—A colored man, calling himself "Dr." S. M. Miller of Boston, who has been claiming to cure all diseases by selling the patient a necktie and "throwing in" a bottle of alleged medicine, has been arrested on complaint of the Lawrence County Medical Board, and despite his plea that the bottles contained nothing but water, was sentenced to pay a fine of $50 and to be imprisoned for six months, for practicing medicine without license.

CALIFORNIA.

Verdict Against Hospital.—A judgment for $350 against the French Hospital, San Francisco, was rendered, September 21, in the damage suit for $2,450 brought by Charles Pala, who claimed to have been unnecessarily burned by a hot-water bag while a patient at the hospital.

Epidemic at McCloud.—The investigation instituted by the State Board of Health regarding the epidemic of typhoid fever at McCloud has disclosed the facts that milk cans from a dairy in the neighborhood were washed in water from a stream

contaminated by sewage, and found to contain the typhoid bacillus.

The Law and the Doctors.—Luigi Gardini and G. B. Gerino, San Francisco, have been arrested, charged with practicing medicine without license.——Samuel R. Chamley, San Francisco, the cancer "specialist" whose license to practice was recently revoked by the state board, has begun an action against the board in the Superior Court, to have the revocation declared void, contending that the statute of Aug. 1, 1901, under which the board acted, is unconstitutional.

Personal.—Dr. Hubert N. Rowell, Berkeley, was kicked in the side by his racing mare, fracturing three ribs.——Dr. Robert F. Winchester, local surgeon for the Southern Pacific Railway at Santa Barbara, has resigned.——Dr. Beverly S. Nourse, Sacramento, has been appointed physician to the State Penitentiary, Folsom, vice Dr. A. B. Plant, resigned.——Dr. and Mrs. Dudley W. Stewart, Los Angeles, celebrated their fortieth wedding anniversary, September 9.——Dr. A. M. Smith has been appointed surgeon for the Southern Pacific Railway at Merced, vice Dr. William A. Whitlock, resigned.

CONNECTICUT.

Winsted Hospital Gets Bequest.—By the terms of the will of the late Salmon Swift the entire estate is devised to the Litchfield County Hospital, Winsted. The estate is appraised at from $5,000 to $10,000.

Infectious Diseases.—During August 6 cases of smallpox were reported, 80 of measles, 107 of scarlet fever, 1 of cerebrospinal fever, 89 of diphtheria. 43 of whooping cough, 170 of typhoid fever, and 15 of tuberculosis. A decided increase was noted in typhoid fever, the August average for the five preceding years having been 150.

August Deaths.—During August 1395 deaths were reported, equivalent to an annual mortality of 17.8 per 1,000. Of this number, 496, or 35.5 per cent., were due to infectious diseases, including diarrhea. Consumption caused 113 deaths; diarrhea, 290; nervous diseases, 166; heart disease, 79; violence, 73; whooping cough, 29; typhoid fever, 28; pneumonia, 51, and typhoid fever, 13.

A Plea for Medical Inspection of Schools.—The State Board of Health, in its August Bulletin, makes the following eloquent plea for medical inspection of schools:

> The laws of Connecticut are imperious in compelling attendance at school during school age. The laws of nature are more imperious and infallible than the laws of man. It is one of the laws of nature that a school child staying in the same school room with another who has a contagious malady is liable to contract such disease and then must accept its fate to endure it until recovery or a fatal termination.
>
> If our lawmakers compel our children to take such exposures, it is surely their duty to take every known means to reduce to the minimum the risk to health and life.
>
> It has been demonstrated that in all our well-filled public schools dangerous contagious diseases are continually present. It has long been observed that epidemic diseases are more prevalent during the school sessions than in the vacation periods. It is not the school children only that are concerned—the general public is involved.
>
> The situation is a simple one, but full of reasons for anxiety and solicitude. Our public schools have been determined by the surest tests to be centers of infection of dangerous diseases.
>
> The laws of Connecticut compel the exposure of our well children to incur this serious risk. Do not the dictates of humanity demand that immediately a life-saving service be organized and established? The most effective means of safety known is a daily systematic medical inspection of all the schools and the exclusion of such pupils as have contagious diseases until they recover.

DISTRICT OF COLUMBIA.

Bequest to Hospital.—By the will of Anna D. Mansfield of Washington, $5,000 is bequeathed to the Episcopal Eye, Ear and Throat Hospital, to be known as the Charles Davies Mansfield Memorial Fund, to maintain a bed in the hospital.

Well-Known Anatomist Dies.—Adolph J. Schafhirt, for many years an employe of the Army Medical Museum, an expert anatomist and preparer of sections and specimens, and a frequent contributor to medical literature, died at his home in Washington, September 14, aged 62.

Under New System.—On October 1 the Emergency Hospital and Central Dispensary, Washington, was placed under the entire charge of a male medical superintendent, who is in fiscal and professional control of the affairs of the institution. Dr. Charles S. White, Washington, is the first incumbent under the new system.

New Filtration Plant.—By the aid of a congressional appropriation of $3,500,000, Washington is installing a filtration plant on land 35 acres in extent, on which filtration beds are being constructed. There are 29 distinct reservoirs, into each of which the water is filtered through beds of clean sand. When the sand becomes polluted, the water is cut off from that particular division and the sand taken out and cleansed. The beds are thus renewed in rotation, 4 of the 29 being always in process of cleaning. An article describing the filtration system of water purification appears on pages 850 to 852 of this issue of THE JOURNAL.

ILLINOIS.

Aged Physician Injured.—Dr. David R. McKinney, Gifford, fell from a train near Fithian, Ill., September 16, breaking his left leg and right arm.

Grant's Home a Hospital.—General Fred D. Grant, and his brothers and sister, wishing to preserve the Grant homestead in Galena, have presented it to the city and it will probably be converted into a hospital.

Oglesby Hospital Incorporated.—Oglesby Hospital Association, Decatur, was incorporated September 2, the purpose being to establish and maintain a hospital ward for the sick and helpless veterans of the Civil War.

Hospital for Children.—The Cook County Board has instructed the county architect to draw up plans and specifications for a hospital for children on ground adjoining Cook County Hospital, the expense not to exceed $50,000.

Combination of Dental Schools.—The College of Dental Surgery of Chicago has been merged with the dental department of the University of Illinois. During the present college year both schools will be continued and the usual courses given.

Personal.—Dr. Lewis D. Dunn and wife of Moline entertained the physicians of Moline, Rock Island and Davenport, September 18, the occasion being Dr. Dunn's birthday anniversary. Dr. Peter H. Wessel, on behalf of the guests, presented Dr. Dunn with a chain and locket.

Sanitary Condition of Cities.—Late in August the State Board of Health began a systematic investigation of the sanitary conditions of all towns in the state of 2,000 or more inhabitants. It is the intention of the board that an inspector shall personally visit each city and confer with the health officer or the board of health and also with the local physicians; inquiring into unsanitary conditions, investigating the system of sewerage and water supply and making such recommendations and giving such advice as may be found necessary. It is the intention also to have a careful chemical and bacteriologic analysis made of all public water supplies. The analyses will be conducted in Chicago under the direction of Professor Long, chemist of the board. The administration of the act to regulate the practice of medicine will also receive the attention of the inspectors, as well as the administration of the birth and death law of 1903. Dr. E. F. Baker, inspector of the State Board of Health, handed in a report, September 22, of his investigation of the sanitary conditions in the cities of Quincy, Pittsfield, Virden, Belleville, East St. Louis, Alton, Jerseyville, Collinsville, Edwardsville, Madison and Litchfield. He reports the sanitary conditions in each city to be good, with the exception of Edwardsville, where a large ravine exists, into which the sewage of the city empties. This was found to create a bad condition of sanitation, and the authorities were asked to remedy the matter, and promised to do so.

Chicago.

Personal.—Dr. L. Harrison Mettler has been appointed consulting neurologist to the Norwegian Lutheran Deaconess Home and Hospital.

Acquitted.—Dr. Ladislaus Slominski, who was held to the grand jury on the charge of performing a criminal operation, has been exonerated by the grand jury.

Fined for Speeding.—Dr. Leonard L. Skelton, whose automobile is said to have injured a man, was fined $10 and costs by Justice Doyle for exceeding the speed limit of the West Park ordinance.

Cornerstone Laid.—Mrs. Helen Barker, treasurer of the National Woman's Christian Temperance Union, laid the cornerstone of the Frances E. Willard National Temperance Hospital, September 28.

Deaths of the Week.—During the week ended September 26, 498 deaths were reported, equivalent to an annual mortality of 13.76 per 1,000. Acute intestinal diseases caused 61 deaths; consumption, 45; violence, 46; heart disease, 41; Bright's disease, 34, and pneumonia, 32.

Early Medical Chicago.—The city of Chicago has been celebrating its centennial during this week. One hundred years

ago the United States sent some soldiers to the spot where Chicago now stands, and they built a fort, which was called Fort Dearborn. The building of this fort in 1803 was the foundation of the city of Chicago. The first physician of record in Chicago was John Cooper, a surgeon's mate from Poughkeepsie, N. Y., who entered on his duties at Fort Dearborn, Dec. 31, 1810. He was succeeded by Dr. Isaac Van Vorhis, also from Dutchess County, N. Y. He was killed in the Fort Dearborn massacre, Aug. 15, 1812. The first civilian physician was Dr. Alexander Wolcott, who was also Indian Agent at Fort Dearborn in 1820. Ten years later Dr. Elijah D. Hamon came to Chicago and entered private practice, also acting as post surgeon. He was in charge of health matters when cholera was brought to the city by the United States troops in 1832. The first medical college—Rush—was incorporated in 1837, but lectures were not given until Dec. 4, 1843. A year later the first medical college building was erected at Dearborn Ave. and Indiana St., the present location of THE JOURNAL, and the first course of lectures commenced Dec. 11, 1844. The first medical society was the Cook County Medical Society, whose initial meeting was held Oct. 3, 1838, Dr. Levi D. Boone being secretary. The first general hospital was established in a portion of the old Lake House at Rush and South Water Sts., in 1850, with 12 beds. As those who had promised to support the hospital failed, the hospital was turned over to the Sisters of Mercy on the condition that it was to be undenominational and that clinical facilities be offered to medical students. The City Hospital was established at La Salle St. between Cross and Old Sts. in 1856, and was opened in November of the next year with a capacity of 300 beds. The first city board of health was appointed in 1834 and consisted of Drs. William Cluet and Edmund S. Kimberley.

The first directory of Chicago was published in 1844, at which time Chicago was a rapidly growing town of 7,000 inhabitants. This directory contains the cards of twelve physicians, practically all who were practicing in the town, showing that even in 1844 physicians in small towns did not disdain to advertise. The following cards will illustrate the style:

V. A. BOYER,
PHYSICIAN AND SURGEON,
JUSTICE OF THE PEACE.
OFFICE.—CLARK ST. nearly opposite the City Hotel.

DOCTOR BLANEY,
Professor of Chemistry and Materia Medica,
IN RUSH MEDICAL COLLEGE,
May be consulted professionally, at his office, on Clark Street, near South Water St. Dr. B. will also attend to CHEMICAL ANALYSIS, in all its branches.

DANIEL BRAINARD, M.D.
PROFESSOR OF ANATOMY AND SURGERY,
In Rush Medical College,
Office on Clark St. Opposite the Post Office.

DOCTOR H. H. BRAYTON.
Having established his residence permanently at
CHICAGO,
Respectfully tenders his professional services to the inhabitants of the City. TWENTY-FIVE years' Study and Practice, and constant application to professional duties, he hopes will entitle him to the confidence of those who may demand his Services.
FRESH VACCINE VIRUS
Now, and always on hand. Office & Residence
On the East side of CLARK ST. first door South of the Methodist Church.

DOCTOR J. BRINKERHOFF,
Office Clark Street, Opposite Public Square.
DRUG STORE, 143 LAKE ST.

DOCTOR EGAN
Can be consulted in private cases at his Residence or Office, but cannot attend to out-door practice.

M. L. KNAPP, M.D.
PROFESSOR OF OBSTETRICS, &c.
In Rush Medical College, Chicago,
May be consulted professionally at the Mansion House,
NO. 82 LAKE STREET.

The cards of a homeopath, Dr. R. E. W. Adams, and of Drs. John W. Eldridge, Benjamin F. Hale and D. S. Smith, also appear.

And at this early day the quack was there:

PHRENOLOGICAL AND MAGNETIC EXAMINER,
At His Residence, 2nd House N. of the Ep. Church,
DR. TEW,
MAY be consulted in all cases of Nervous or Mental difficulty.—The application of his Remedies will enable him to relieve, or cure, any case of Monomania, Insanity, or recent Madness, where there is no inflammation or destruction of the Mental Organs. His attention to the diseases of the Nervous System, such as the St. Vitus' Dance, Spinal Affections, has resulted in some remarkable Cures. Having been engaged, for the last five years, in teaching Mental Philosophy, as taught by Phrenology, together with his numerous Phreno Magnetic Experiments, enable him to give correct and true delineations of Mental Dispositions of different persons; which will be every way profitable to all who wish to understand the mysteries of their own natures, and how they may use their talents to the best advantage.

The announcement of Rush Medical College in the directory referred to gives the faculty as consisting of Danial Brainard, M.D., Professor of Anatomy and Surgery; James V. Z. Blaney, M.D., Professor of Chemistry and Materia Medica; John McLean, M.D., Professor of the Theory and Practice of Medicine; M. L. Knapp, M.D., Professor of Obstetrics and Diseases of Women and Children, and A. W. Davisson, Prosector to the Professor of Anatomy. The name of E. S. Kimberley, M.D., also appears on the list of trustees. It is announced that "the annual course of Lectures for the first session commences on Monday, December 4, 1843, and will continue sixteen weeks"; that "the requirements for graduation are three years' study with a reputable physician, two courses of lectures, one of which must be in this institution (or two years' practice will be received in lieu of one course). The candidate must be 21 years of age, of good moral character, must present a thesis on some medical subject of his own composition, and in his own handwriting, which shall be approved by the faculty; and pass a satisfactory examination on all the branches taught in this college." In conclusion, it is stated that "Good board and room can be obtained in Chicago at from $1.50 to $2 per week." Happy times now past!

INDIANA.

College Opens.—The Central College of Physicians and Surgeons, Indianapolis, opened for its twenty-fifth year, September 22.

Much Typhoid.—For the first half of September 56 cases of typhoid were reported in Indianapolis, two more than for the corresponding period of last year. The board of health is actively examining well water, and condemning wells.

Personal.—Dr. C. Homer Stalker, Borden, has been appointed assistant physician at the Indiana State Soldiers' Home, Lafayette.——Dr. A. Grant S. Brubaker, Indianapolis, was thrown from his buggy, September 12, and severely bruised.——Dr. Bruce Easley, New Albany, has gone to Europe.

Deplore Hibberd's Death.—The City Council of Richmond met in special session, September 10, and passed resolutions eulogistic of the character of Dr. James F. Hibberd. The Allen County Medical Society held a special meeting at Fort Wayne, passed resolutions and deputed Dr. Miles F. Porter to represent the society at the funeral.——The Wayne County Medical Society passed resolutions eulogistic of "its most distinguished member."

LOUISIANA.

Illegal Practitioner Enjoined.—The State Board of Medical Examiners secured an injunction against "Dr." D. O. Holmes, 1306 Magazine St., New Orleans, restraining him from practicing medicine in Louisiana, on the ground of his being an "illegal practitioner."

Typhoid Reports Requested.—The City Board of Health has issued a circular letter to the physicians of New Orleans urging their co-operation in tracing the sources of typhoid in-

fection, and reminding them that it is their duty under the law to report all cases of typhoid fever. The health officer states that a death certificate is often his only notification.

Asylum Overcrowded.—The State Insane Asylum, which has a capacity for about 1,200 patients, now contains 1,353, and more than 100 applications are on file. Owing to the congested condition of the dormitories it has been necessary to place cots in some of the corridors formerly used as sitting rooms. To relieve this congestion, an insane asylum for colored persons is being built at Pineville, Rapides Parish, which will accommodate about 450 patients.

Alarming Increase of Insanity.—In speaking of the increase of insanity throughout the country, Dr. G. A. B. Hays, superintendent of the State Insane Asylum at Jackson, says that he had recently visited Missouri and Texas and found that the situation was as bad as in Louisiana. Both these states have several asylums and each is having a new one erected. From this fact Dr. Hays contends that the conditions now obtaining in Louisiana are not peculiar to that state alone but are simply an expression of a state of affairs that is widespread throughout the country.

Prisons for Insane Criminals.—There are a number of criminals who have been adjudged insane, confined in the Louisiana State Insane Asylum. The superintendent thinks that this class of insane should be held in some specially-prepared portion of the state prison, where they could be placed under proper treatment and at the same time have the possibility of escape minimized. Not long ago one of the assistants at the asylum narrowly escaped death at the hands of one of these men. The handling of these patients should be the subject of special attention.

Cottages for Insane Consumptives.—Dr. G. A. B. Hays, superintendent of the Louisiana State Insane Asylum, suggested to the board of directors of the asylum that two cottages be erected for white consumptives now in the asylum, one for each sex. The matter was favorably considered by the executive committee and will be submitted to the board at its meeting October 5. The matter of sequestering the insane suffering from tuberculosis is one that has been acted on in a number of asylums in other states, and it would greatly alleviate the lot of the unfortunate inmates if the plan is carried out in Louisiana.

MARYLAND.

Personal.—Dr. Walter Hutchins, My Lady's Manor, Md., has gone to New Mexico for his health.

Typhoid Investigation.—Health Officer Dr. Christian R. Scheller, Hagerstown, is investigating the cause of the epidemic of typhoid fever at Clear Spring, Washington County, where 31 cases are reported.

A Nuisance.—Dr. F. A. Ruhl, sanitary officer of the Thirteenth District, Baltimore County, has reported the Claremont Chemical Company's plant at Sextonville a nuisance and "dangerous to health." "Inhaling of the dangerous gases lowers the vitality of the body and causes headaches, nausea and irritation of the respiratory organs."

Baltimore.

College Opens.—The twenty-third annual session of the Baltimore Medical College opened September 24 with an address by Prof. J. Frank Crouch.

Death and Disease.—The number of deaths for last week was 171, an annual death rate per 1,000 of 15.80. The chief causes of death were consumption, 30; cancer and cholera infantum, each 11; Bright's disease, 10; pneumonia, 6, and typhoid fever, 4. The most prevalent epidemic diseases were diphtheria, scarlet fever and typhoid fever; one case of smallpox was reported.

Personal.—Drs. Howard Kelly and William Osler returned home last week.——Dr Harry M. Hurd is spending his vacation in the Blue Ridge Mountains.——Dr. John T. King has returned from a trip abroad.——Dr. Charles Lewis Allen, formerly connected with Georgetown University Medical School and Vanderbilt Clinic, has been made lecturer on nervous diseases in the University of Maryland.——Dr. Alan Welch Smith has located in Portland, Ore.

PENNSYLVANIA.

Philadelphia.

New Buildings Opened.—New buildings containing operating rooms and an amphitheater were recently opened at the Samaritan Hospital.

Bequest to Hospital.—The late Samuel Cummings left an estate of $40,000 bequeathed to his widow, which, on her death, is to be equally divided among four institutions, the Methodist Episcopal Hospital being one of the four beneficiaries.

One American Selected.—The International School of Hygiene has selected one man from each country in the world as a representative. Dr. J. K. Shell of Philadelphia is invited to represent the United States at the next annual conference at Güttenburg, Germany, next fall.

Woman's College Opens.—At the opening of the Woman's Medical College, September 23, it was announced that to fill vacancies in the faculty Dr. Edith Womer Cadwalader had been elected professor of obstetrics and Dr. Ruth Webster professor of physiology and hygiene. The chair of anatomy made vacant by the death of Dr. William H. Parrish will not be filled this year.

Poisoning Case.—In the trial of Emma Williams, charged with poisoning her children, several medical experts have testified that the children died with symptoms of arsenical poisoning. The chemical expert testified to finding several grains of arsenic in organs examined. One line of defense announced is that the children were poisoned by "spit balls" which they made of wall paper. An effort has been made to show that the colored herb "doctor" Hossey supplied the poison to the accused.

Appeal for Jefferson.—Hon. William Potter, president of the board of trustees of Jefferson Medical College, in his introductory address on September 24, made a strong appeal for the benevolence of the wealthy in behalf of his own and like institutions concerned in the saving of human life. While great liberality has marked the giving to libraries and other institutions of learning, gifts for the endowment of medical schools have been strangely meager. President Potter spoke in high terms of the Jefferson Hospital now building, and announced the purchase of properties in Walnut street, where it is proposed to erect a nurses' home.

The Typhoid Epidemic.—For the week ended September 26 there were 81 new cases of typhoid fever. The health authorities who have been energetic in their efforts to find the source of infection in sections of the city where the disease has been almost epidemic—districts supplied with filtered water—have, they believe, found the true sources. In addition to infected milk supplies, it has been discovered that a well and a spring from which many secured their drinking water are contaminated. While the typhoid bacillus was not detected in the water, it was found to contain the colon bacillus and other impurities, indicating contamination from cesspools. Eighteen new cases of smallpox were reported for the week.

GENERAL.

Yellow Fever Close to Texas.—One case of yellow fever was reported from Laredo, Mexico, last week, which is just across the Rio Grande from Laredo, Texas. The number of guards patroling the river has been increased and all communication between the cities stopped. A case is again reported from Monterey and again denied. United States officers say the truth is hard to obtain. In Victoria only a dozen cases now exist, and the authorities think they will soon have the disease stamped out. Tampico now has seven cases weekly, and the number is diminishing. War against the mosquito is carried on.

FOREIGN.

Police Regulations in Prussia Against Hypnotism Exhibitions.—The Prussian authorities have cautioned the police against allowing any exhibitions of magnetizing, suggesting or hypnotism or any such measures.

Pasteur Treatment of Hydrophobia at Rome.—The mortality among the patients treated at this institute, which is in charge of Professor Celli, has been only .5 per cent. since its organization in 1899. During this period 2,000 persons have received treatment, averaging about 38 a month.

The Sanatorium Movement in Denmark.—The National Antituberculosis Association was founded in Denmark two years ago, and has now 30,000 members. A model public sanatorium has been just opened at Silkeborg, the first in the country. It has accommodations for 122 patients, with 112 rooms facing the south. Each patient has a minimum of 900 cubic feet of space.

Quinin in Italy.—All the provinces of Italy now have quinin bisulphate for sale everywhere, standardized by the government and sold at the postoffice in places without a drug store. The

maximum price allowed to be charged is about two and a half cents a gram, and the charitable organizations are supplied with it to be distributed gratuitously among the poor in the most malarial regions.

False Testimonial Ends Insurance Benefit.—A German manufacturer was in regular receipt of an indemnity paid by a sickness insurance company, on account of a serious stomach trouble. He recently applied to a charlatan, and in order to obtain a reduction in the charges of the latter signed a certificate to the false effect that he had been entirely cured of his stomach trouble after a week's treatment. This certificate was published in the charlatan's ads with the consequence that the insurance company naturally at once suspended further payment of the indemnity.

Popularizing Medical Lore in Russia.—The St. Petersburg Red Cross Society has inaugurated a two years' course of instruction of laymen in the principles of hygiene, disinfection, massage, emergency operations, internal, venereal and cutaneous affections, surgery, etc. The practical demonstrations will be given in a military hospital, and in some of the city public hospitals. The aim of the course is to disseminate information among the people in regard to the onset and care of disease, and diplomas will be conferred on those who complete the course. Our medical exchanges regard the project with disfavor, fearing that the smattering of knowledge thus gained will be an incitement to enter the ranks of the charlatans.

The Anti-Seasickness League Ship for the Lisbon Congress.—The Ligue contre le Mal de Mer chartered a vessel on the occasion of the International Congress at Moscow in 1897 and conveyed a number of members of the congress from England to St. Petersburg and return. The league now proposes to have a ship in readiness for the International Medical Congress at Lisbon in 1906. The vessel will start from Hamburg and touch at intermediate ports, taking the members after the congress to the Mediterranean European ports. It is proposed to install in the vessel a complete exposition of everything bearing on the subject of the prevention of seasickness, and to institute experiments on the passengers on request. The permanent address of the league is Ligue contre le Mal de Mer, Paris V, Boulevard Porte Royale 82.

The Syphilized Chimpanzee.—It is announced from Paris that the chimpanzee successfully inoculated with syphilis this summer now presents the symptoms of the secondary stage. When Metchnikoff and Roux exhibited the animal at the Académie de Médecine, July 28, the primary chancre was recognized as specific by Fournier and others, and the eruption, swollen glands and enlargement of the spleen are now likewise qualified as specific by experts, as Metchnikoff proclaimed at one of the meetings of the International Congress of Hygiene and Demography, which has just closed its sessions at Brussels. Attempts to inoculate other monkeys from this animal—selecting those a degree further removed from man—have proved negative. It seems to be established by this research that the anthropoid apes alone are susceptible to syphilis. The previous communications on the subject were reviewed in THE JOURNAL, page 752.

Crusade Against Tuberculosis in Buenos Ayres.—Stringent measures have been enacted in Buenos Ayres and a penalty of about $192 is enforced for every householder who neglects to comply with the regulation that every house in which a tuberculous person has passed even a single day is to be regarded as infected and disinfection required. Spittoons are to be placed in all public places holding carbolized water renewed twice a day and a penalty of $2 to $5 enforced if a person spits elsewhere than into the receptacle provided. Spitting on the floor of street cars is punished by a fine of about $10; the police are instructed to enforce these regulations. Public vehicles must be thoroughly disinfected twice a year and their floors twice a week. Cars must be disinfected with formalin once a month. No tuberculous person is to be allowed to serve as waiter, cook, butcher or deal in any way with articles of food. Repetition of an offense entails a double penalty.

Cancroin in the Austrian Hospitals.—When Adamkiewicz first presented his cancroin for the treatment of cancer, Albert and Billroth offered him every opportunity in their clinics to prove its efficacy. After the most thorough tests and long experience they concluded that the remedy had no curative action nor power to arrest the disease. Their verdict has not been contradicted in the medical world during the ten years since, but the minister of the interior has recently notified the public hospitals throughout the empire that cancroin must be now given a thorough and objective testing, and a special ward for the treatment of cancer by this method is to be established in some hospital and placed in charge of Adamkiewicz. Our Austrian exchanges comment, as might be expected, on this innovation, which is such a contrast to the usual lethargy in regard to medical matters on the part of the administration—"usually it requires years of red tape before a university, to say nothing of any special faculty, is able to obtain a microscope or even some needed washstand, and every request for some of the modern, well-tried remedies always meets with the reply that the testing of new drugs is not in the province of the hospitals." The Austrians have been chagrined lately over the refusal of a number of prominent German professors to accept the chairs left vacant at Graz, Innsbrück and Vienna by the death or retirement of eminent men. One after another declined as the chairs were offered to them.

International Congress of Hygiene and Demography.—September 2 to 8 witnessed the gathering at Brussels of the eleventh international congress of hygiene and demography, the semi-centennial of such assemblies. There were 1,900 registered members, and 500 were delegates from various countries. The congress was a model of perfect organization we are told. More than 100 sessions were held in all, and each discussion occurred at the time and place as planned from the outset. Among the resolutions adopted was one favoring preventive antidiphtheria treatment and tests of the antimicrobian strength of the antitoxin as well as its antitoxic power. Another resolution adopted was to the effect that "infant consultations" under the care of physicians should be established, and that young girls should be given practical instruction in the hygiene of infants, visiting the "consultations," etc. Circulars proclaiming that bottle feeding can never take the place of breast feeding should be given with the marriage license and when a birth is declared. A number of resolutions were voted in regard to school hygiene and prophylaxis of the plague, among them one to the effect that quarantine against the plague should be abandoned when possible to substitute close surveillance for ten days, reducing it to five days if the passengers consent to prophylactic inoculation with antiplague serum, even when cases of plague have occurred on the vessel during its trip. Ships touching at infected ports should be supplied with antiplague serum so that passengers and crew could be vaccinated when plague occurs on board. The physicians entrusted with the prophylaxis of the plague should be appointed by the central powers, independent of the navigation companies. In regard to tuberculosis, the resolutions were based on the principle that it is eminently a social disease. In the section on demography the statistics presented confirmed the fact that infantile mortality is mainly during the first year, and Bertillon pointed out that 90 per cent. of the infants succumb to a microbian affection, and that the aim should be to treat infants with the same care with which a wounded person is tended. The pressing need is for the mothers to be educated in the principles of asepsis. The section adopted a resolution urging that the accessory circumstances should be recorded with the births, including the premature and the stillborn. The next congress will be held at Berlin in 1907, a national congress of hygiene at Marseilles in 1904, a congress of physical education at Geneva in September, 1904, and a section on hygiene will be one of the features of the international and universal exposition which Liège is preparing for 1905.

Correspondence.

The Danger of Methods Often Used at Present in Dusting Waiting Rooms, Cars and Other Public Places.

BALTIMORE, Sept. 21, 1903.

To the Editor:—The day before yesterday on my return from the Parry Sound District in Canada, at the close of a long holiday, I was delayed for about an hour in the Pennsylvania railroad station at Harrisburg. It was in the small hours of the morning, and being weary I nodded and fell asleep for awhile as I sat on the bench, only to be suddenly awakened with a stifling, gasping, choking sensation caused by thick clouds of dust raised by two sweeping men who were vigorously plying their brooms and stirring up all the desiccated filth deposited on the floor by the great continuous traffic of the previous day and night. The waiting room was crowded, late as it was, and all who remained in the room were forced

to breathe the pulverized debris which had been tracked in from the streets, mingled with the dried expectorations of hundreds of men, women and children of the preceding day.

I need not argue so transparent a case with any intelligent medical man, nor need I dwell on the variety of infectious diseases of the respiratory passages, coryza, bronchitis, whooping cough, pneumonia, tuberculosis, as well as diphtheria, etc., etc., which are at present disseminated over the length and breadth of our land, day by day, by just such atrocious death and disease-dealing procedures, which sin against the simplest and best-known laws of hygiene.

As for myself, although in splendid health ever since I left this country for Europe on April 10 last, I developed immediately a fever and a wretched cold in the head, which is traveling down through my larynx, producing a cough and almost completely unfitting me for work for a few days.

My object in writing this letter to THE JOURNAL is to enlist the entire medical profession as a committee on the whole to expostulate in strong terms, to insist, to write vigorous letters to the daily papers if needs be, or even perchance to be almost ready to resort to personal violence to put a stop to such atrocious practices.

I want my confrères to note the great prevalence of this practice of atomizing the dried filth of our streets and forcing people to inspire it, in many public institutions, in hotels, and in Pullman cars. I am sure it must have long been an offense to many decent clean men to be obliged to submit to breathe the dust thrown in their faces by the currents of air raised by the whisk broom of the Pullman porter as he belabors the coat, the trousers, the hat and the overcoat of the next dusty passenger. Dr. McCormack tells me that the street cars of Baltimore are cleaned by a woman, who enters the car when it goes into the shed and raises clouds of dust with her duster, much of which settles in the upper parts of the car. The car then goes out, and as it jumps over the rails the light dust descends to be inspired by the passengers.

In spite of the general corrupt political state of our country I think a continued vigorous protest from the countless thousands of natural guardians of the public health, my brethren of the medical profession, would soon effect a radical change in the methods of removing and collecting dust and filth from floors and clothes, as it appeals so directly to the selfish instinct of self-preservation.

Let me ask this pertinent question: What right have you or I, my medical brother, to be longing for the dawn of a new era in medicine when we shall be in possession of a toxin for every disease, for tuberculosis and for kindred ailments, so long as we fail to utilize the far better and simpler efficient methods of preventing disease which we already have at hand, when, for example, such a city as Philadelphia, once noted for its cleanliness, becomes conspicuous for its filthy streets, when in our homes, in our streets, in our public places, that most modest of all virtues, cleanliness, holding in her beneficent hands a reduction of the morbidity and of the mortality of so many of the scourges of our modern "civilization," to a point far below 50 per cent. of its present ratio, when cleanliness, I say, is unknown? Must we have magic to please our people? Must the remedy be a poison manufactured in a dramatic way and injected into the veins of the disease-stricken patient, in order to arouse our languid interest?

We put the whole noble army of bacteriologists to utter blushing shame when, as a result of all their arduous labors, they give us such a preciously simple remedy, when after having explained the causes of many of our most frightful diseases in a manner so simple that a child in a kindergarten can both understand the method of invasion and apply the remedy; we shame them I say when, after having thus done all the most sanguine imagination could have proposed, we dumbly plod along the same old dusty, dirty road, waiting to crown the discoverer of an antitoxin.

The specialist in disease of the lungs, throat and nose may exclaim that these are but trite observations, the very A, B, C of his science, iterated and reiterated in medical society meetings. But I care not how old the observation is or how often repeated if men do not heed it. And of one thing I am certain, and that is that the dormant medical profession at large is the proper police body to take the body politic by the throat and shake it out of its disgraceful lethargy.

A distinguished president of one of our great universities told me some ten years ago that he had joined an association known as "the kicking society," the members of which were obliged to object every time they saw gross violations of the law and injustice done.

Let us constitute then a kicking society from Maine to California and insist on clean streets, clean houses, clean public buildings, and clean cars. Let it be recognized as a grave offense and an insult to force a neighbor to inhale myriads of pathogenic germs. The primary inviolable right of every man is to pure air and pure water and sunlight when the sun is shining. See, my brethren, that he is not robbed of his rights.

HOWARD A. KELLY, M.D.

Mental Status in Phthisis.

NEW YORK CITY, Sept. 14, 1903.

To the Editor:—Under the above title a correspondent in THE JOURNAL of the American Medical Association, August 29, p. 767, asks two questions concerning the mental condition of patients with pulmonary tuberculosis. May I, by reason of a somewhat extensive experience with phthisical patients, be permitted to reply and start a discussion, trusting that the interesting subject may cause others, specialists in phthisiotherapy, and particularly general practitioners, to express their opinions through the medium of THE JOURNAL?

The family physician more than anyone else should be heard from on this subject, for he must of necessity be more familiar with the psychologic and mental condition of the members of a family which he has attended for years, than the specialist or consulting physician could be.

The first question was: "Are persons who are afflicted with pulmonary consumption prone to attribute their physical weakness to some other cause than consumption?"

Yes, many consumptives are apt to do so, but the reason for this is not a condition brought about by the disease itself, but by the fear of the disease. Invalids know that many people will shun, or wish to shun them if they are called consumptives. Many still consider phthisis an incurable disease, and try to delude themselves, their families and friends as long as possible, feeling that to pronounce them consumptives would be to sign their death warrant. Others have no suspicion of their true condition and are sure they have no tuberculous disease. Thus I have not infrequently seen consumptives, even among the most cultured and educated, who would ascribe a hemorrhage from the lungs to a little bleeding from the throat or nose; the cough to bronchitis or to a derangement of the stomach; the pleuritic pains to intercostal neuralgia or heart trouble; their general weakness to an overtaxing of the nervous system. I have even found medical men suffering from tuberculosis who believed their symptoms were due to anything and everything else except to the development of a typical pulmonary phthisis.

Whether and when it is wise to leave the patient under these delusions will largely depend on the state of mind of the individual invalid and the good judgment of the physician. At times I have found it best to dispel all such illusions at once; in other cases it was necessary to proceed gradually and with the utmost tact. In view of the infectiousness and the curability of the disease under proper care the patient should, as a rule, be made acquainted with his true condition as soon as possible. If he is told that he will get well quicker if he calls his disease what it is and takes proper care, than if he calls it something else and neglects it, he will have more courage, be in a better mental condition and will then be careful not to infect others or reinfect himself.

The second question was: "Are persons afflicted with pulmonary consumption more easily turned against their dearest friends by designing people than when in a normal state of health?"

I would answer this strange query with a most emphatic

"No." If such instances occur they are the exception, not the rule, and are then due to a peculiar psychologic state of the individual. Consumptives as a class are grateful to their friends, physicians and nurses and devoted to their families. At the beginning of the disease, it is true, a decided irritability may often be noticed, with a dislike or indifference to pleasure or work; but beyond this no distinct psychologic changes can be observed. Many consumptives are very sanguine about the outcome of their disease, others are depressed, some totally indifferent. Even in the case of a fatal termination most of them retain a clear intellect until the last. The character and disposition of the consumptive varies as it does in well people; but to say that by reason of his disease he is easily turned against his friends by designing people would be absurd and do him the greatest injustice.

There is enough phthisiophobia in the world already, and let us not give the phthisiophobic another cause to increase his fear of or dislike for the unfortunate consumptive. Thousands of these are as noble, true and generous as any other class of invalids or well people.

Consumption is a preventable, curable, communicable, but by no means a dangerously contagious disease. Among those who were once afflicted with it and were ultimately lastingly cured we count the brightest minds, the most generous and truest hearts. The German poet Goethe, our own Peter Cooper, the French poet Coppée, were among them. The greatest German specialist Herman Brehmer, who cured himself, and thousands of others from this disease; his two greatest contemporaries and co-workers, still alive and active. Dettweiler in Germany and Trudeau in this country, all are examples of the highest type of men. The story of the lives and work of those who have passed on and those still with us give evidence of their great qualities of heart and mind, their truth and devotion to friends, family and mankind in general.

Suggestive Therapeutics vs. Hypnotism.

Chicago, Sept. 26, 1903.

To the Editor:—In The Journal, Sept. 26, 1903, appears an editorial under the above heading, which challenges some comment. . . . Hypnotism, as now understood by men who have had personal experience with it, is really synonymous with suggestion. The Charcot school is responsible for the term artificial hysterical state occasionally cropping up in medical literature. Charcot conducted his experiments with hypnotism on about a dozen or more hysterical patients which were demonstrated to the whole world in order to prove his theories. The peculiar method used and the frequency with which these patients were hypnotized contributed toward their becoming perfect automatons of unconscious suggestion. Hypnotism as practiced now is nothing else but suggestion administered during a state of greatest susceptibility to suggestion. I can not conceive how you can recommend suggestive therapeutics and condemn hypnosis when to successfully practice the first the second is often an absolute necessity. Not all people are alike suggestible and particularly are hysterical patients refractory to suggestions from without, for they are mostly dominated by autosuggestions. If suggestion is to be of value it must be administered during the time of greatest susceptibility. Many people are susceptible to suggestion in the waking state and these are the proper subjects for indirect waking suggestions by means of innocuous drugs, electricity, etc. In some cases we are forced to place such patients into the condition of greatest receptivity for our suggestions, I mean into hypnotism. The so-called dangers from hypnotism are imaginary, and although I have hypnotized hundreds of times I have never seen any ill effects from its use. Bernheim, Liebault, Ford, Wetterstrand and a host of others who practiced hypnotism thousands of times have had similar experiences. Because of the Mendel commission having assumed an unfavorable attitude toward hypnotism is no valid argument against its use by the physician in properly-selected cases.

Julius Grinker, M.D.

Physiology in the University College of Medicine.

Chicago, Sept. 28, 1903.

To the Editor:—My attention has been called to the fact that in my report on Curriculum in the National Confederation of State Medical Examining and Licensing Boards (The Journal, Aug. 15, 1903, pp. 456-461), the University College of Medicine, Richmond, Va., is not credited with any work in physiology. This college devotes to this study 53 hours of lectures and 27 hours of recitations. I am informed by the proctor that the number of hours has been increased for the coming session. Any other errors noted in the above report will be corrected most cheerfully if sent to the undersigned.

70 State Street. George W. Webster, M.D.

The Visiting Physician in Berlin.

by denslow lewis, m.d.
chicago.

(*Concluded from page 798.*)

With a slight knowledge of social usage and with the ability to speak the language to a reasonable extent, the American visitor's sojourn in the German metropolis will be most enjoyable and profitable. The wealth of clinical material is unsurpassed elsewhere, and the sensible manner in which it is utilized will be appreciated. The friendly reception extended to Americans and the invariable courtesy that prevails on all sides combine to make the visitor welcome and to facilitate his studies. The months of April and August are vacation months when many medical men leave town. The months of March and October are also vacation months, but especially valuable to the medical visitor for the vacation courses (*Ferienkursen*) are given at this time. These courses are unusually interesting, for it is here that the younger teachers have a chance to exploit themselves and the older men to bring forward prominently special points in diagnosis and treatment. The cost is insignificant. For ten dollars a month you can see Lexer and others connected with Bergmann's Klinik perform major operations every morning, and you can do minor operations yourself in the Poliklinik, where over 20,000 patients are treated every year.

If one's stay is to be protracted it is well to matriculate and be enrolled as a student. It is imperative to show a passport, and it is customary to present the diploma. I had forgotten to bring either, but I procured the passport from our Embassy for about ten marks and I showed the dean a copy of my "Obstetric Clinic" I had with me to give to Olshausen. In arranging to matriculate consult the man in charge, called the "*Pfoertner*," or better still, his wife, who is an English woman. They keep the buffet in the university building and supply the student with information as well as sandwiches and drinks. They told me the day and hour I was expected to appear in person and qualify.

When the appointed time arrived I found myself, together with some fifty others, seated in the "*Aula*," as the assembly hall of the university is called. At one end of this hall is a throne or pulpit arrangement with leather chairs in front and seats along each side of the room. I learned afterward that this is where the candidate for graduation takes leave of the university by publicly defending three theses before all the world—a function known as "*promovieren*." At the other end of the room is a large table at which are seated several dignified gentlemen who superintend the matriculation. When my name was called I approached the table and was interviewed by the gentleman at the end. He looked at my passport and compared the name with the name in my book on obstetrics. Being satisfied apparently with my credentials, I was directed to the rector, who wrote my name and his own on a large Latin document, which I deciphered later and learned that it was my certificate of matriculation. I then passed along to another gentleman, who had me write my name and address in a large book. The next gentleman had me write my name on a numbered student's card, which I was instructed always to have on my person and which, I learned afterward, exempted me from arrest or interference by the police. The next

gentleman, who is the "*Ober-Pedell,*" collected eighteen marks and gave me my "*Anmeldebuch,*" in which to record the lectures attended. I went back to my seat and waited until all present had similarly run the gauntlet. Then the rector arose and made a short speech. He said we had all done well at our high schools and he hoped we would do equally well at the university. He admonished us against the temptations of the metropolis, and we formed in line and marched past him so that each one could receive from him the academic handshake. The medical students were directed to meet the dean the next day at a stated hour, on which occasion, by showing our student cards and matriculation certificates, we received another Latin document of smaller size, which indicated that we were inscribed as students of medicine.

The next thing to do is to decide which lectures are to be chosen, or, as here expressed, "*belegt.*" You must choose at least one course or your name does not appear in the catalogue. You have the first six weeks of the semester in which to look the field over and make a decision. During this time you visit the different men, hear them teach or see them operate. This is called "*hospitieren.*" Having made your choice you visit the "*Questor*" at the university building between the hours of 9 and 1, and in addition to paying for the courses you select you pay also twelve marks and a half each semester for incidentals, including free medical attendance in case of illness or accident. The amount paid and the courses chosen are written in the "*Anmeldebuch,*" which must be taken to each professor for his signature at the beginning and end of each semester. When leaving the university a certificate of attendance called an "*Abgangszeugniss*" can be procured by the payment of twelve and a half marks and the presentation of your "*Anmeldebuch*" properly attested. This certificate shows the studies you have "*belegt,*" and in conventional terms it is stated regarding your conduct while a student of the university that there is "*Nachteiliges nicht zu bemerken,*" that is, "nothing detrimental to be remarked."

Regarding the different courses of clinical instruction I will not now write in detail. The medical man who contemplates visiting Berlin will soon learn about them on arrival or, at trifling expense, he may procure the announcements in advance through almost any American bookseller. Many of the best courses are free and no one will ask for the student card at the others. Indeed, in some of the best-known courses few persons pay the fee. Lassar's course on skin diseases, for example, is "*belegt*" by only five or six in a semester, although his auditorium is crowded every day. He often jokes about this, but he is so popular and so extremely amiable that every visitor is made welcome. The vacation courses, however, must be paid for, as well as all special arrangements for individual instruction. The facilities for instruction of this kind are ample, so that, at insignificant expense, one may pursue almost any line of study in the most practical manner.

Some of the best operating is absolutely free. Israel, Krause, Sonnenberg, Körte, Hoffa, Rotter; Dührssen, Mackenrodt, Jansen or Neumann—Hahn's successor at Friedrichshain—may all be seen, each at his respective klinik, by presenting your visiting card. To see Olshausen, who is the best known gynecologist in Germany, it is advisable to make a formal call about 5 o'clock, at his residence adjoining the Frauenklinik, of which he is the director. He is a most affable gentleman and will invite you to be present at his laparotomies, which occur early each morning. It is customary to give his "*Portier,*" who is in charge of the door of the Frauenklinik, about two marks a week if you are a constant visitor. You will receive from him a postal card every day, and if the case is urgent he will telephone you or send a messenger in search of you.

A few words, in closing, about graduation at the Royal Friedrich-Wilhelm University, as the institution is called in Berlin. Three Americans graduated there last summer and another from New York is now a student. These gentlemen all began their medical studies in Berlin. On matriculating they were obliged to show their passports and a "*Zengniss der Reife,*" that is, evidence of having an amount of knowledge equivalent to that possessed by a graduate of a German gymnasium. This is perhaps represented by the completion of the sophomore year at one of our American colleges. When candidates for graduation they had to show nine semesters' work, including anatomy, chemistry, physics, physiology, histology, biology, internal medicine, obstetrics and gynecology, surgery, ophthalmology and two semesters of pathology. They visited the dean, paid 440 marks each for the examination and presented their credentials. A day or two afterwards they were called before the dean for the "*tentamen medicum,*" which is a written examination lasting two hours. The subject assigned may be in any department of medicine. On one occasion last July the subjects were puerperal eclampsia, preparation and therapeusis of atropin, pernicious anemia and croupous pneumonia. The next day the result was announced and the day set for the "*examen rigorosum,*" which was oral.

There are three divisions of the faculty composed of five members—commissions as they are called—who conduct this examination. The candidate may be assigned to either commission. In one instance he will be examined in anatomy, obstetrics and gynecology, materia medica, ophthalmology and internal medicine. In another commission the professors represent pathology, physiology, surgery, internal medicine and obstetrics and gynecology, while the third commission examines on neurology, hygiene, surgery, pediatrics and anatomy. Of course, each professor may examine in any department of medical science, but he rarely goes outside of his own. The candidates, faultlessly attired in evening clothes, present themselves by appointment at 5 o'clock at the dean's office, where they are received by each member of the commission in turn. Each interview lasts an hour. The number of candidates at any one time may not exceed five. Wine and cake for their refreshment are on a table in the anteroom. Shortly after 10 o'clock, when all five professors have compared their markings, the result is announced.

When a candidate does not pass he may be re-examined at the end of the next semester by paying a small additional fee. When he does pass he is said to have graduated "*rite,*" that is, successfully, or "*cum laude,*" meaning with praise. My young friend Teague of Alabama received this honor last July. The other two distinctions, *magna cum laude*" and "*summa cum laude,*" are rarely attained by foreigners. Once during the past four years an Armenian received the "*magna,*" and his thesis was considered so exceptional that the dean added an extra point, which entitled him to the "*summa.*"

The thesis, or "*Arbeit,*" as it is called, is prepared under the direction of a privat docent or professor, who assigns a subject, supplies the bibliography or, if the subject is clinical, provides the patients. When completed it must be approved and recommended to the dean as the "*Doktorarbeit.*" The dean examines it and the candidate is directed to a printer, who will strike off 440 copies, 340 of which remain the property of the university, at an expense of 120 to over 200 marks, according to its length. The page proof is submitted to the dean, who either signs it immediately or keeps it to look over. The printer is fined for printing an "*Arbeit*" without the dean's approval. The page proof approved by the dean is kept by the printer, who prints on the title page the date of graduation, a date also ordered printed on the diploma.

The last function when the candidate receives his parchment diploma, also a duplicate on heavy paper and seven printed copies, is known as "*promovieren.*" It takes place in the "*Aula*" of the university at a set hour—usually 2 o'clock. The candidate defends three propositions, called "*Thesen,*" before all the world. He arranges for three opponents to be present, one to speak against each proposition. When my friend Stephens of Tennessee went through the ordeal I had the honor to be one of his opponents. I put on evening clothes, brushed my silk hat, polished my patent-leather shoes and invested in a pair of white kid gloves. Thus attired I joined the candidate at the appointed hour. His friends were seated at either side of the room, while he and his opponents, all in full dress, awaited the entrance of the dean. Presently the door at the other end of the room opened and the dean

advanced toward us. He was dressed in a flowing gown of red silk or velvet and wore a large turban of the same material. The candidate met him at the middle of the room and presented him with a bound copy of the "*Arbeit*," which contained the three "*Thesen*" to be defended and the names of the opponents. The dean seated himself at one side, the opponents in front of the stage, the candidate mounted the rostrum and reading off a set form in Latin declared that he had fulfilled all requirements and was now prepared to defend three "*Thesen*," which, with permission. he would read in the German language.

When my turn came the candidate announced that in puerperal eclampsia immediate delivery is indicated. I knew, of course, the day before that I was to dispute this proposition, and I had told the candidate he might as well maintain that it was light when the sun was shining. I arose and remarked that even if the delivery were immediate aseptic precautions should not be forgotten, for it was hardly worth while for a woman to recover from eclampsia if she were fated through neglect to die later of sepsis. I referred to Löhlein's statistics, the best in the world, and I called to mind that his treatment was morphin hypodermically. The candidate gave me a look of scorn. He told us that the practitioner of to-day realized the value of asepsis, and it was, he hoped, unnecessary to insist on it on every occasion. As regards Löhlein's twelve cases, he maintained that the number was insufficient on which to generalize, much less to attempt to formulate a treatment. Indeed, his own experience, as "*Unterarzt*" at the Frauenklinik, was much greater than Löhlein's, and for that reason, if for no other, he must persist in his demand for immediate delivery in those cases. Under this denunciation all I could do in reply was to acknowledge the candidate's contention.

When all three opponents had been vanquished the candidate asked if any one else had anything to say against his propositions. He stared his friends on either side of the room boldly in the face, but no one ventured a word. The candidate with an air of triumph then bowed to the dean, who ascended the pulpit and called the candidate to him to administer the Hippocratic oath. This completed, the dean made some more remarks in Latin—undoubtedly felicitous in character—and presented the diploma. The candidate replied with more choice Latin, in which I understood that he was bidding good-bye to the dean, the university and the assembled guests. The dean now offered his congratulations and retired while the candidate —now a candidate no longer, but a full-fledged M.D.—received the good wishes of those present.

The diploma does not entitle the recipient to practice. Indeed, among the Germans it is an honor and not a necessity. The essential thing is to have passed the "*Staatsexamen*." The German student is a graduate of a gymnasium or "*Realschule*" and matriculates as described. He studies first anatomy, physiology, chemistry, physics, botany and zoology for at least four semesters and then applies for examination in these branches. He must show that he has passed this "*physicum*"—which is an oral examination—before he can attend clinical lectures. At the beginning of the tenth semester the student may apply to the government for permission to take the "*Staatsexamen*." He must show in addition to his attendance on lectures nine "*Praktikantenscheine*," that is, certificates that he has stood the quiz before the class to the satisfaction of the professor. Two of these certificates must be in obstetrics and gynecology, two in surgery, two in internal medicine, one in children's diseases, one in ophthalmology, and one in vaccination. It is rumored that a tenth certificate—the subject not announced—will soon be required. The "*Staatsexamen*" is an oral examination and very difficult. It is usual to examine three days in each subject, and it takes about six months to complete. The title received is "*Praktischer Arzt*," or practicing physician, and is a license to practice. If the "*Doktorwürde*," or degree of M.D., is also desired the applicant must write "*Arbeit*" and "*promovieren*," but the commission that now examines him orally is composed of three instead of five members of the faculty.

92 State Street.

Marriages.

JOHN G. CRAIG, M.D., to Miss Alma Willett, both of Chicago, September 16.

J. J. DALLAL, M.D., to Miss Ellen Collins, both of Norcatur, Kan., September 2.

EVLAN SARGENT, M.D., to Miss Winnie Compton, both of Moline, Ill., September 9.

JAMES M. BLAINE, M.D., to Mrs. Ida Ladair Green, both of Denver, Colo., September 16.

GEORGE D. MORTON, M.D., Philadelphia, to Miss Josephine H. Griswell of Norwood, Pa., June 30.

REIN K. HARTZELL, M.D., Allentown, Pa., to Miss Jennie A. Kuntz of Treichlers, Pa., September 15.

JOHN HENRY SIEDLER, M.D., Buffalo, N Y.., to Miss Theresa Marie Brick, at Brantford, Ont., September 9.

LEONARD E. WELCH, JR., M.D., Albany, Ga., to Miss Frances Laundis of Alabama, at New York City, September 9.

CHARLES F. CULVER, M.D., Sioux Falls, S. Dak., to Miss Grace Isabel Cameron, of St. Paul, Minn., September 2.

BEN PERLEY WEAVER, M.D., to Miss Lucile Porter, daughter of Dr. Miles F. Porter of Fort Wayne, Ind., September 16.

WILLIAM JORDAN TAYLOR, M.D., Cincinnati, son of Dr. William H. Taylor, to Miss Katharine Warren Weston of New York City, at Cascade-in-the-Adirondacks, N. Y., September 16.

Deaths.

Robert Newman, M.D. Long Island College Hospital, Brooklyn, 1863, for many years a member of the American Medical Association, and of the New York State and County Medical associations, died suddenly at his country residence, Monument Beach, Mass., August 28. He was an honest, painstaking and indefatigable worker in the field of electrotherapeutics, and suffered not a little for his persistent advocacy of the treatment of urethral stricture by electrolysis. During the past year his friends had noticed with regret that his health and strength were on the wane, but he would not listen to their admonitions, and insisted on working to perfect the arrangements for the meeting of the American Electrotherapeutic Association. Even gout and dysentery could not curb his will, and he continued to attend to his practice until his wish to "die in harness" was gratified, for his death came to him while he was sitting in his office chair.

Hugh Morrison Lash, M.D. Cincinnati College of Medicine and Surgery, 1870, professor of mental and nervous diseases in the Central College of Physicians and Surgeons, Indianapolis; consulting physician to the Union State Hospital; member of the American Medical Association, Indiana State Medical Society, Marion County Medical Society, and some-time president of the Indianapolis Medical Society, and a member of the city board of health, died from cardiac asthma at his home in Indianapolis, September 19, after a long period of ill health, aged 59. At a special meeting of the Indianapolis Medical Society, September 20, eulogistic resolutions were adopted.

Samuel Hollingsworth Stout, M.D. University of Pennsylvania, Philadelphia, 1848, surgeon and medical director of hospitals of the Department of Tennessee in the Confederate service during the Civil War, some-time professor of surgical and pathologic anatomy in Atlanta Medical College, and at the time of his death emeritus professor of medicine in Baylor University College of Medicine, Dallas, died at his home in Clarendon, Texas, September 18, aged 81. The Dallas County Medical Society, at a specially-called meeting, appointed pallbearers and committees on resolutions and flowers.

Luther Martin Irwin, M.D. Rush Medical College, Chicago, 1882, of Lafayette, Ind., a member of the Indiana State Medical Society, and once vice-president of the Tippecanoe County Medical Society, died suddenly from heart disease in the office of Dr. Richard B. Wetherill in that city, September 17, aged 48. The Tippecanoe County Medical Society, at a special meeting, September 18, pronounced eulogies on Dr. Irwin and appointed committees on resolutions and flowers.

Andrew H. Kimbrough, M.D. Jefferson Medical College, Philadelphia, 1858, a charter member of the Vermilion County Medical Society, and a member of the Illinois State Medical Society

for many years, died at his home in Danville, Ill., September 17, after an invalidism of two years, aged 70.

Isaiah D. Morgan, M.D. University of Pennsylvania, Philadelphia, 1858, a surgeon in the Confederate service during the Civil War, and local surgeon of the Alabama Great Southern Railway, died at his home in Eutaw, Ala., September 17, after an illness of more than a month, aged 73.

Charles Gardiner, M.D. Jefferson Medical College, Philadelphia, 1879, a member of the American Medical Association and a prominent surgeon of Emporia, Kan., died suddenly from heart disease while performing an operation in Emporia, September 24.

Eli Edwards Josselyn, M.D. New York University, 1873, a physician in the woman's department of the Pennsylvania Hospital for the Insane, Philadelphia, died suddenly in a corridor of that institution, September 13, from heart disease, aged 57.

William M. Cox, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1860, a member of the American Medical Association, died at his home in Mount Sterling, Ill., September 14, from persistent hiccough, after an illness of one week, aged 65.

Egbert Guernsey, M.D. New York University, 1846, New York City, for many years editor of the *Medical Times*, died at his summer home in Fishkill Landing, N. Y., September 19, from bronchopneumonia, after an illness of five days, aged 80.

Benjamin G. Kimmel, M.D. Miami Medical College, Cincinnati, 1870, of Youngstown, Ohio, died at the City Hospital, Youngstown, September 19, from skull fracture received in a fall from his bicycle the day before, aged 62.

John K. Dick, M.D. Rush Medical College, Chicago, 1890, formerly of Champaign, Ill., died at his home in Lincoln, Ill., September 20, from typhoid fever, after an illness of three weeks, aged 49.

James S. Hall, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1875, was found dead in his store at Manville, Wyo., September 16, supposedly from the effects of an overdose of morphin.

Franklin N. Morton, M.D. Eclectic Medical Institute, Cincinnati, 1871, died from brain disease at his home in Little Cooley, Pa., September 19, after an illness of ten days, aged 68.

John C. Rhoden, M.D. Rush Medical College, Chicago, 1896, of Elk Point, S. Dak., a member of the American Medical Association, died in a hospital at Council Bluffs, Iowa, September 19.

R. Howard Edmonston, M.D. University of Buffalo, Brooklyn, N. Y., died at the Kingston Avenue Hospital, Brooklyn, September 8, from diphtheria, after an illness of four days.

William Taliaferro, M.D. of Tappahannock, Va., died at the University Hospital, Baltimore, September 17, from diabetes, which appeared after an operation for carbuncle, aged 58.

Will Stephens, M.D. Barnes Medical College, St. Louis, son of Dr. Andrew J. Stephens, died in his father's office, September 21, from the effects of morphin taken with suicidal intent.

Warren H. Blood, M.D. Cooper Medical College, San Francisco, 1885, died at his home in West Oakland, Cal., September 12, from pneumonia, after an illness of two weeks, aged 39.

John A. Draughon, M.D. Bellevue Hospital Medical College, New York, 1875, of Nashville, Tenn., died at the home of his daughter in Springfield, Tenn., September 18, aged 49.

Myron S. Brownson, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1871, died at his home in Kingsley, Mich., September 20, after a lingering illness, aged 58.

Robert Bruce Shaw, M.D. McGill University, Montreal, 1896, of Charlottetown, P. E. I., died September 13 at the Massachusetts General Hospital, Boston, from appendicitis.

Charles S. Williamson, M.D. University of Maryland, Baltimore, committed suicide by taking poison at Winifred, Kanawha County, W. Va., September 15, aged 26.

Theodore Hartwig, M.D. University of Marburg, Germany, 1845, who came to Cedarburg, Wis., in 1846, died at his home in that place, September 20, aged 83.

A. S. Hayley, M.D. Louisville Medical College, 1883, of Yakima City, died at the North Yakima Hospital, September 9, after a long illness, aged 40.

Thomas J. Barton, M.D. Albany (N. Y.) Medical College, 1855, of Tivoli, N. Y., died at the Albany City Hospital, September 11, aged 73.

Joseph Bechtel Mintzer, M.D. Medico-Chirurgical College, Philadelphia, 1891, died at his home in Philadelphia, September 18, aged 48.

Bennie E. Grove, M.D. Kansas City (Mo.) Medical College, 1900, died at his home in Augusta, Okla., September 9, from typhoid fever.

Wesley M. Landon, M.D. Cincinnati College of Medicine and Surgery, 1863, died at his home in Quincy, Ill., September 11, aged 75.

Murdock McLean, M.D. University of California, San Francisco, died September 13 at Placerville, Cal., from fever.

Deaths Abroad.

Dr. Matheus dos Santos, professor of hygiene and president of the medical faculty of Bahia, Brazil, died in Berlin last month.——**Dr. V. V. Muravieff**, an eminent Russian neurologist, died at Moscow, August 20.

Miscellany.

Five-Cent Novel Medicine.—In a "powerfully written and graphically portrayed" story for boys, price five cents, entitled "The Knowlhurst Mystery, or the Strange Adventures of Leslie Norton," appears the following choice bit:

When the doctor had declared that he was too late, he really believed Peter Norton to be dead.

The little clot of blood which had formed on the base of the brain had so numbed him that coma, like unto death, had set in.

A very slight movement of the muscles of the neck caused the doctor to try an experiment.

He had with him a little pellet of nitroglycerin.

It was a new invention, and the physician trembled at the consequences of using it.

It might destroy the little vitality left, or, on the other hand, it would, perhaps, give life and power to the heart.

In Norton's case, the doctor felt safe in using it, for he was convinced nothing short of the almost miraculous could restore him to life.

He opened the old man's teeth, and placed the pellet on his tongue.

There was no attempt made at swallowing it.

A small quantity of whiskey, poured gradually on the tongue, caused the pellet to glide softly down the throat.

Presently the effect was seen.

The nitroglycerin had dissolved; the shock was felt in every part of the body.

Norton's face became purple, then gradually the blood diffused itself over his body; the shock had dispelled the clot. He opened his eyes and looked around; then closed them, and fell into a calm sleep.

Medical organization in the United States has at last made a movement that will only result in a most satisfactory success, says the *Southern Practitioner*. Since the grand meeting at New Orleans quite a number of states that were hanging back, hesitatingly, doubtingly, as if the movement was one possibly to result in binding them to means and measures that were not calculated to result in general good, have accepted the method of reorganization as suggested, of making the county membership the unit of representation. By the plan now satisfactorily demonstrated to be the only correct and practical one, we have a definite representative body, controlled by the membership of the profession at large through their duly qualified and selected representatives in their state organizations; those in their turn selecting the representatives in the National organization, to whom is entrusted the welfare, individually and collectively, of the profession. In our own state, since the annual meeting held in this city, quite a number of counties have placed themselves in line, and fifty-two county medical societies, composed of the best and most representative men in their respective localities, have been chartered as regularly affiliated and component societies of the State Medical Association. This has so far resulted in increasing more than three-fold the membership in the state organization; and with the work that will be carried on during the months intervening between now and the next annual meeting, we have every reason to believe that but few, if any, counties in the state will fail to affiliate with and be represented in the state association. Furthermore, in counties in which a fair organization had previously existed, there has been quite an accretion of membership. To our friends in this state, as well as in others, we would respectfully but earnestly say—organize! *organize!!* yes, ORGANIZE!!! If you have no organization in your county, at once take steps to get one properly under way. If you have a county organization, and it has not yet properly affiliated with your state organization, see to it that it does so before the next annual meeting; and if you *have* a properly organized and affiliated

county medical society, do not let your efforts rest here, but go on with the work, and induce any reputable member of the profession within your acquaintance to join you and your associates. Individual work with your clientele, in your library, in your laboratory, at the bedside of your patients, is all very well; yet a little time given to your county, state and National organizations will benefit both you and your patients in many ways. It is a duty you owe to yourself, to the profession of which you are a member, and to your patrons. No man has a greater necessity for organization and conference with his fellows than the physician. No one can be greater benefited thereby. If medical science and medical and surgical success depended alone on empiricism, each one might flock by himself, and the most successful would be the one with the best memory to remember and utilize the uncertain methods and measures of the empiric. Yet how much grander, how far more beneficent results will accrue to each and every one, and those relying on them, if each one from day to day brings his grains of observation and place them in a granary to which all have access. Again we say, organize in your counties, hold your meetings weekly, semi-monthly, monthly, quarterly or semi-annually, the oftener the better, and if but two or three are gathered together at each meeting, only good can come from your conference, and others will soon be induced to follow the good example you set them. One question we would ask—and its answer will be as strong an argument for organization as could be desired—whether you have been a member of the medical profession one year or fifty years—you know something about the standing of other medical men—then, who occupy the best, the most enviable, the most satisfactory position socially or professionally? Now just take a look around—and whether it be far or near—in the great metropolitan centers of the nation, in the larger towns and cities of your state, do you not find at the head of the profession men who are identified with medical associations? Whether in county, state or National association you will find the cream of the profession—its most progressive, its most successful members—if they can see a benefit therein, why not you?

Book Notices.

A Nurse's Handbook of Obstetrics. For Use in Training Schools. By Joseph Brown Cooke, M.D., Fellow of the New York Obstetrical Society. Cloth. Pp. 391. Price, $2.00. Philadelphia and London: J. B. Lippincott Company. 1903.

The author has endeavored to bring together the principal points that the monthly nurse must know, or ought to know, to make herself an efficient helper. The illustrations are good and the instructions given seem to us in the main sensible and complete.

My Child and I. In Sickness and Health from Pre-natal Life Until Sixteen. By Mrs. F. L. S. Aldrich, M.D., Member of the American Medical Association. Cloth. Pp. 429. Price, $1.50. Philadelphia: P. W. Ziegler & Co. 1903.

This is a book for the laity. The statements made seem to be in the main fairly correct, and the book may be taken, in general, as a fairly reliable guide for parents. The only difficulty is that it may lead to too much home treatment, to the child's disadvantage. The book is rather showily gotten up and has some moderately good pictures. Its style is good.

Quantitative Chemical Analysis. Adapted for Use in the Laboratories of Colleges and Schools. By Frank Clowes, D.Sc. Lond., Emeritus Professor of Chemistry in the University College, Nottingham, and S. Bernard Coleman, A.R.C.Sc. Dublin, Professor of Chemistry in the Southwestern Polytechnic, Chelsea, S. W. Sixth Edition. Cloth. Pp. 602. Price, $3.50 net. Philadelphia: P. Blakiston's Son & Co. 1903.

In this new edition of Clowes and Coleman's well-known work on quantitative analysis numerous alterations and additions have been made in the text. The section on organic chemistry has been revised and the processes of determining molecular weight by the elevation of the boiling point and for the analysis of aluminium alloys have been added. New woodcuts illustrative of the above molecular weight determination process, a new form of container and of the method of drying in vacuo have been inserted. Tables of four-figure logarithms have also been introduced to facilitate calculation.

A Text-Book of Surgical Principles and Surgical Diseases of the Face, Mouth and Jaws. For Dental Students. By H. Horace Grant, A.M., M.D., Professor of Surgery and Clinical Surgery, Hospital College of Medicine. Octavo Volume of 231 Pages, with 68 Illustrations. Cloth. Price, $2.50 net. Philadelphia and London: W. B. Saunders & Co. 1902.

This little work was written for the dental student. The author makes no claim to original thought, nor does he present an elaborate or scientific discussion of the subjects considered. About one-third of the work is devoted to surgical principles; bacteriology, inflammation, repair, general infections, etc. Then follows a brief description of the various affections of the face, mouth, jaws and neck, presented in a plain, simple manner, such as would interest the dental student, for whom the work was written. It is not comprehensive nor scientific enough to be of material value to the surgeon.

The Exact Science of Health Based Upon Life's Great Law. By Robert Walter, M.D. Vol. I.—Principles. Leather. Pp. 302. Price, $2.00. New York: Edgar S. Werner Publishing Company. London: Kegan Paul, Trench, Trubner & Co., Ltd.

There are books that are published for various purposes; in many cases the author gets so full of the subject that it is woe to him if he does not preach his gospel with the aid of printer's ink. The present work probably gives much more satisfaction to the author than it will to the average reader. The main point which he apparently tries to make is that there are three great forces in nature, vitality, chemical affinity and gravitation, co-existent and analogous. In this way he is practically a sort of materialist; we can not say that he has proven his case, or that his arguments and reasoning are such as would convince others as to the probability of his views.

A Thesaurus of Medical Words and Phrases. By Wilfred M. Barton, M.D., Assistant to Professor of Materia Medica and Therapeutics, and Lecturer on Pharmacy, Georgetown University, Washington, D. C.; and Walter A. Wells, M.D., Demonstrator of Laryngology and Rhinology, Georgetown University, Washington, D. C. Flexible Leather. Pp. 534. Price, $2.50 net; with Thumb Index, $3.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

The value of a volume like this for the physician who writes is so evident that it is a little remarkable that one has not been produced before. The authors have given a very complete list of technical synonyms, and the book will be correspondingly of service. It is neatly gotten up and is evidently the result of a good deal of careful labor. Worthy of note is its dedication to Dr. John B. Hamilton, the late editor of The Journal, as an appreciation of the services which he rendered the authors and as a tribute to his learning and skill. We believe that the book will be a very useful one.

The Latin Grammar of Pharmacy and Medicine. By D. H. Robinson, Ph.D., Late Dean of the School of Arts, and Professor of Latin Language and Literature, University of Kansas. With an Introduction by L. E. Sayre, Ph.M., Professor of Pharmacy in, and Dean of Department of Pharmacy, University of Kansas. Fourth Edition, with Elaborate Vocabularies. Thoroughly Revised by Hannah Oliver, A.M., Assistant Professor of Latin, School of Pharmacy, University of Kansas. Cloth. Pp. 277. Price, $1.50 net. Philadelphia: P. Blakiston's Son & Co. 1903.

This is a useful work for physicians and pharmacists. Its study will help do away with the mistakes too often made which show such a lack of culture in the humanities, as they used to be called. The editor states in his preface that a chapter on prescription writing is contributed by Professor Sayre, as well as a list of pharmaceutical and medical terms with their definitions. The latter we find, but the chapter on prescription writing is apparently confined to only a few paragraphs in a chapter on other subjects. A full treatment of the subject would have added to the value and completeness of the book. Aside from this point we see little to criticise. The volume will be a useful one for many students of medicine and pharmacy.

A Text-Book of Chemistry. For Students of Medicine, Pharmacy and Dentistry. By Edward Curtis Hill, M.S., M.D., Medical Analyst and Microscopist; Professor of Chemistry and Metallurgy in the Colorado College of Dental Surgery. With 78 Illustrations, including 9 Full-Page Half-tone Colored Plates. Pp. xii-523. Cloth. Price, $3.00 net. Philadelphia: F. A. Davis Company.

This book of 523 pages includes the subjects of medical physics, chemic philosophy, inorganic chemistry, organic chem-

istry, qualitative and quantitative analysis, incompatibility, sanitary chemistry, toxicology, physiologic chemistry, pathologic chemistry, clinic chemistry, not to mention an appendix and a glossary. The various topics are not handled with any great degree of completeness; as a matter of fact, the attempt to condense has in many instances seemed to be at the expense of lucidity. It is stated that it is intended for the use of students of medicine, pharmacy and dentistry; it is certainly not adapted for a student desiring much more than a quiz-compend knowledge of the subject. As a condensation of the subjects it covers, however, it seems quite complete and accurate. Modern work on physical chemistry seems to have been slighted.

DISEASES AND INJURIES OF THE EYE, with Their Medical and Surgical Treatment. By George Lawson, F.R.C.S. Eng., Surgeon-Oculist-in-Ordinary to Her Majesty, the Late Queen Victoria. Sixth Edition, with 249 Illustrations. Revised and, in Great Measure, Rewritten. By Arnold Lawson, F.R.C.S. Eng., Assistant Surgeon to the Royal London Ophthalmic Hospital. Cloth. Pp. 587. Price, about $5. London: Smith, Elder & Co. 1903.

It seems appropriate that this well-known text-book should be continued by a relative of the great ophthalmologist who first wrote it. The fifth edition was published in 1885, since when several additions have been made to the original chapters. In the present work fresh articles have been written on heterophoria, affections of the eye in disease of the nervous system, the pupil, the development of the eye and elementary optics. Gradually the fact that anomalies of the extrinsic ocular muscles may be productive of functional disturbances without apparent deviation of either eye is gaining ground even in conservative England. Whatever be the status of heterophoria in the causation of symptoms, near and remote, it is at least a considerable satisfaction to notice that this latest of the British text-books does not neglect even the subject of cyclophoria, a condition whose pathology Savage has done so much to elucidate, but which has not received that recognition its importance deserves. We regret that no reference has been made to several instruments which we are accustomed to use on this side of the Atlantic; among them the electric ophthalmoscope and the ophthalmometer with the self-illuminating mires. The illustrations are entirely in black, but are unusually well drawn and, especially when they depict minute changes in the fundus or elsewhere, are, in consequence, more valuable than those glaring color patches that so often in some treatises misrepresent ophthalmoscopic and other findings. The formulæ (seventy in all) at the back of the book, fairly represent the best of the ordinary remedial mixtures now used in diseases of the eye. Probably it is because they have not as yet reached the "text-book age" that dionin, argyrol, jequiritol, and other agents (which some of us believe to be of considerable value) have not been mentioned.

BREWER'S SURGERY. A Text-Book of Surgery for Students and Practitioners. By George E. Brewer, A.M., M.D., Lecturer on Clinical Surgery at the College of Physicians and Surgeons (Medical Department of Columbia University), New York. With 280 Engravings and 7 Plates in Colors and Monochrome. Cloth. Pp. 712. Price, $4.00. Philadelphia and New York: Lea Brothers & Co. 1903.

The author has attempted to write a text-book on surgery in a single small volume of six hundred and eighty pages. The author says he "has endeavored in the present work to give the essential facts in practical surgery as briefly as is compatible with clearness." While brevity and condensation in writing are often desirable qualities, there is such a thing as condensing matter until all the information which it contains is squeezed out, and that is what the author has done frequently in this work. For instance, the subject of gangrene in all its varieties is covered in twenty lines. Only seventeen pages are devoted to "tumors," and as there are several large illustrations included in these seventeen pages, the text amounts to little more than a simple definition of the various kinds of new growths. Under treatment of aneurisms is mentioned "the subcutaneous injection of a 1 per cent. solution of gelatin in normal salt solution," but nothing is said of the amount to be injected; of the necessity and great difficulty of thoroughly sterilizing gelatin solutions, and of the danger of fatal tetanus (which has occurred now a number of times) following the use of solutions of gelatin not properly sterilized. In a matter of this kind the advice to use a solution of gelatin without giving the details of the method is positively dangerous, and brevity becomes a great mistake. Ganglion is described as "a hernial protrusion of the synovial membrane through the fibrous portion of a tendon-sheath." This is a mistake, as the majority of so-called ganglions have no connection whatever with the tendon sheaths. The spasmodic and the contractured varieties of torticollis are confused and considered as one affection, although they are decidedly distinct conditions. The treatment of empyema is dismissed with a single sentence as follows: "The treatment of empyema is by establishing free drainage of the pleural cavity." The success of the treatment, however, depends so much on the method and detail of carrying it out that a little advice here would have been desirable. The freezing point of the blood serum is given as 0.36 C. This is evidently a typographical error, as it should be 0.56 C. Ligations of arteries, amputations, etc., are considered in the stereotyped way, except perhaps a little more condensed. Brevity is the greatest fault of the work, as many of the subjects are considered so superficially that the practitioner will usually look in vain for advice that will help him out of his difficulties, but to the student who is obtaining his first general idea of surgery the work may prove of value.

State Boards of Registration.

Indiana's First Preliminary Examination of Students.—The first examination of prospective medical students held by the Indiana State Board of Medical Registration, was held at the State House, Indianapolis, September 18; 15 applicants appeared.

Texas Announcement.—The Board of Medical Examiners for the State of Texas will hold its next meeting in Fort Worth, Oct. 13 to 16, for the examination of applicants to practice medicine. For further information address the secretary, Dr. M. M. Smith, Austin.

Georgia Examination.—The regular board of State Medical Examiners for Georgia will meet in Atlanta, Ga., on Tuesday, Oct. 13, 1903, at the Capitol, for examination of applicants for permanent license. A diploma from a medical college recognized by the Medical College Association is required.

Virginia Report.—Dr. R. S. Martin, secretary of the Medical Examining Board of Virginia, reports that at the examination held at Richmond, June 22 to 25, 1903, the number of subjects examined in was 9 and the percentage required to pass was 75; 196 persons were examined, 99 passed, 22 failed, 3 withdrew and 72 were not graduates and took only a partial examination. The questions were partly written and partly oral.

Connecticut Report.—The report of the examinations by the examining committee of the Connecticut Medical Society, July 14 and 15, is received. The percentages are not given; all that passed exceeded 75. those that failed were below this figure. Of those that passed 8 were graduates of the medical department of Yale University, 4 of the College of New York, 4 of the College of Physicians and Surgeons, New York, 4 of the Baltimore Medical College, 2 from Jefferson Medical College, 2 from the University of Vermont, and one each from the Cincinnati College of Medicine and Surgery, the Royal College of Physicians and Surgeons, London, Medical College of South Carolina, Harvard Medical College, New York University, Niagara University, Cornell University and Long Island College Hospital. Of those that failed 4 were from the College of Physicians and Surgeons, Baltimore, and one each from the College of Physicians and Surgeons, Boston, University of the South, Tufts Medical College, and the medical department of Yale University.

Iowa Report.—Dr. J. F. Kennedy, secretary of the Iowa State Board of Medical Examiners, Des Moines, reports that 149 candidates were examined in June and July, of whom 128 passed and 21 failed.

Medical Organization.

Monroe County (Fla.) Medical Society.

By the efforts of Dr. Joseph N. Fogerty, Key West, councilor for the Fourth District, a reorganization of the old Key West Medical Society, which was organized in 1872, and discontinued in 1884, was effected with the following officers: Dr. Robert D. Murray, president; Dr. Emilio Rousseau, vice-president; Dr. G. R. Plummer, U. S. Navy, secretary, and Dr. Katharene W. Allee, treasurer, all of Key West.

Putnam County (Ohio) Medical Society.

At Ottawa, Ohio, on August 27, under the direction of Dr. Julius H. Jacobson, Toledo, councilor for the Fourth District, this society was organized with the following officers: President, Dr. John C. McClung, Leipsic; vice-president, Dr. C. F. Douglass, Kalida; treasurer, Dr. Warren F. Reed, Ottawa; secretary, Dr. Wiley D. Hickey, Leipsic, and board of censors, Drs. Charles E. Beardsley, Ottawa, Harry A. Lewis, Continental, and Dr. Alva L. Paul, Ottawa.

Pocahontas County (Iowa) Medical Society.

The physicians of Pocahontas County recently met at Pocahontas and organized a county society, adopted the constitution and by-laws as recommended by the American Medical Association and elected the following officers. Dr. Andrew L. Belt, Gilmore, president; Dr. Edmond W. Wilson, Rolfe, secretary and treasurer; Dr. I. D. Wallace, Plover, vice-president; Drs. A. H. Thornton and J. W. Starr, Pocahontas, and Frank E. Heathman, Havelock, censors, and Drs. Oscar H. Barthel, Pocahontas, Charles R. Whitney, Fonda, and J. D. Wallace, Plover, committee on public health and legislation.

South Dakota Second District Medical Society.

On September 15 about twenty-five physicians met Dr. Edwin T. Ramsey Clark, councilor for the Second District, at Watertown and completed the organization of a medical society for that district, which comprises the counties of Clark, Codington, Deuel, Hamlin, and part of Grant. The constitution and by-laws recommended by the American Medical Association were adopted and Dr. Edwin T. Ramsey, Clark, was elected president, and Dr. James B. Vaughan, Castlewood, secretary. Meetings will be held every two months, and the whole day will be devoted to the interests of the profession, the morning being taken up with clinics, the afternoon and evening being devoted to the reading and discussion of papers.

Societies.

COMING MEETINGS.

Colorado State Medical Society, Denver, Oct. 6-8.
Medical Association of the District of Columbia, Washington, Oct. 6.
Idaho State Medical Society, Boise, Oct. 8-9.
Mississippi Valley Medical Association, Memphis, Tenn., Oct. 7-9.
Tri-State Medical Society of Alabama, Georgia and Tennessee, Oct. 13-15.
Vermont State Medical Society, Bellows Falls, Oct. 15-16.
New York State Medical Association, New York City, Oct. 19-22.
American Public Health Association, Washington, D. C., Oct. 26-30.
Hawaiian Territorial Medical Society, Honolulu, Nov. 7.
Oklahoma Territory Medical Association, Oklahoma City, Nov. 11.

Colorado State Medical Society.—The annual meeting will be held in Denver, October 6, 7 and 8, under the presidency of Dr. William W. Grant, Denver.

Louisville Medical and Surgical Society.—At the annual meeting held September 21 Dr. Frank J. Kiefer was elected president; Dr. Irvin Abell, vice-president; Dr. A. Henry Falconer, treasurer, and Dr. William T. McKinney, secretary.

Union Meeting.—On September 15 the Cheshire County (N. H.) Medical Society, Franklin District (Mass.) Medical Society, Connecticut River Valley Medical Society and Windham County (Vt.) Medical Society held a joint meeting at East Northfield, Mass.

Carroll County (N. H.) Medical Society.—At the annual meeting held at Sanbornville, September 2, Dr. W. S. Davis, Sanbornville, was elected president; Dr. Ervin W. Hodsdon, Centerville, secretary, and Dr. Nathaniel H. Scott, Wolfboro, treasurer. The 1904 meeting will be held at Wolfboro.

Crawford County (Ill.) Medical Society.—At the meeting held in Robinson, September 10, Dr. Columbus Barlow, Robinson, presented a motion that the constitution be so amended that any legally registered physician in good standing in the county may be entitled to membership in the society. The matter was laid on the table until the next meeting.

Kankakee Valley District (Md.) Medical Society.—At the fourth annual meeting held in North Judson, September 8, Dr. David J. Loring, Valparaiso, was elected president; Dr. John M. Ward, Kewanna, vice-president; Dr. George E. Hoffman, Rochester, secretary, and Dr. G. W. Thompson, Winamac, treasurer. The next meeting will be held in Hammond, December 8.

Association of Surgeons of the Pennsylvania Railway System.—At the annual meeting held in Fort Wayne, September 18, the following officers were elected: President, Dr. G. W. Thompson, Winamac, Ind.; vice-presidents, Drs. Montgomery Linville, Newcastle, Pa., and Clarence W. Coulter, Oil City, Pa., and secretary and treasurer, Dr. Richard J. Morgan, Van Wert, Ohio.

Houghton County (Mich.) Medical Society.—At the annual meeting held in Houghton, September 7, Dr. E. C. Dudley of Chicago delivered an address on "Some Practical Points in Gynecology," and the following officers were elected: Dr. Joseph E. Scallon, Hancock, president; Dr. Albert B. Simonson, Calumet, vice-president; Dr. James E. Hosking, Kearsarge, secretary, and Dr. A. G. McLeod, treasurer.

Mississippi Valley Medical Association.—The program for the entertainment of the members of the association at its meeting in Memphis, Oct. 7, 8, and 9, includes a trolley ride, a reception and ball and an old-fashioned Southern barbecue.——Dr. W. Britt Burns has been made chairman of the committee of arrangements, vice Dr. Edward C. Ellett, resigned.——The

Chicago members of the association will leave Chicago via the Illinois Central at 6:20 p. m. Tuesday, October 6.

Little Kanawha and Ohio Valley Medical Association.—At the annual meeting held in Parkersburg, September 3, the following officers were elected: President, Dr. Thomas A. Harris, Parkersburg; vice-presidents, Drs. Alexander J. Mitchell, Burning Springs, John H. Kelley, Parkersburg, and J. Riley McCollum, St. Mary's; treasurer, Dr. Charles W. Hudson, Parkersburg; secretary, Dr. Rolla Camden, Parkersburg, and assistant secretary, Dr. Steidger D. H. Wise, Parkersburg.

Washington County (Vt.) Medical Society.—The annual meeting was held at Montpelier, September 8. The following officers were elected: Dr. Myron L. Chandler, Barre, president; Dr. Walter D. Berry, Waterbury, vice-president; Dr. Orlando G. Stickney, Barre, secretary; Dr. Charles E. Chandler, Montpelier, treasurer; Drs. Carlos A. Shaw, Northfield, and Michael F. McGuire, censors, and Drs. Lester W. Burbank, Cabot, and Dr. V. C. Goodrich, Barre, delegates to the Vermont State Medical Society.

American Public Health Association.—The following railroad rates have been secured for the thirty-first annual meeting of this association at Washington, D. C., Oct. 26 to 30, 1903: In the New England, Trunk Line, Central and Southeastern territories the rate will be one and one-third fare, certificate plan, for the round trip. A certificate must be obtained from the ticket agent for each going ticket purchased and be presented to Dr. E. W. Reisinger for signature and vise of the special agent at the meeting. First-class tickets must be purchased direct to Washington, free fare one way. No stopovers en route will be granted. A charge of 25c. will be made on each certificate signed at the meeting. Arrangements with Canada and western territory have not been completed, but are expected to agree with rates granted as above. Tickets are on sale three days prior to date of meeting, good to return three days after closing date, Sundays excluded in each instance. At present the rate is one and one-third fare for the round trip, certificate plan, throughout the entire United States, except in territory west of Chicago and St. Louis, Peoria, and north of Missouri River. The committee expects to secure additional time extension on return tickets.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

Sixteenth Annual Meeting, held in Chicago, Sept. 22-24, 1903.

The association met under the presidency of Dr. L. H. Dunning, Indianapolis.

Dr. William A. Evans, Chicago, delivered an address of welcome on behalf of the local medical profession, which was responded to by President Dunning.

The New Officers.

The following officers were elected for the ensuing year: President, Dr. Walter B. Dorsett, St. Louis; vice-presidents, Drs. A. B. Miller, Syracuse, N. Y., and W. D. Haggard, Nashville, Tenn.; secretary, Dr. Wm. Warren Potter, Buffalo, N. Y., re-elected; treasurer, Dr. X. O. Werder, Pittsburg, Pa.

The time and place for holding the next annual meeting of the association were left to the executive council to decide.

Following are some points brought out in the principal papers read.

The Relation of the Colon to Abdominal Tumors.

A paper with this title was read by Dr. James F. Baldwin, Columbus, Ohio. The colon, while it is quite movable, has its mesocolon well fixed to the abdominal parietes. By inflating the colon, when necessary, by pumping air in at the anus, its relationship to abdominal tumors can be quite definitely determined, and this relationship will enable an accurate diagnosis of the tumor to be made in many cases in which such diagnosis would otherwise be impossible. This is particularly true in differentiating tumors of the spleen, pancreas, kidneys, liver, including the gall bladder, etc., from tumors originating in the pelvis or in connection with the small intestine and mesentery.

DISCUSSION.

Dr. J. Henry Carstens, Detroit, had seen cysts of the kidney which were attached to the left side and had extended down into the pelvis, pushing the colon and everything on to the right side, so that it was impossible to differentiate them from a cyst of the ovary.

Dr. L. H. Dunning, Indianapolis, described an echinococcus cyst of the pancreas, which was supposed to be a cyst of the kidney.

Dr. Baldwin said that 95 per cent. of tumors of the pancreas appear above the transverse colon; if at the tail of the pancreas, partly to one side: if at the head, the other side, while tumors of the kidney appear behind the colon. A tumor of the suprarenal capsule might be mistaken for a tumor of the tail of the pancreas, but not of the kidney substance itself, if the colon was fully distended.

Cesarean Section.

Dr. M. Stamm, Fremont, Ohio, read a paper on "The Value of Vaginal Cesarean Section," giving to Dührssen of Berlin the credit for having introduced this valuable method and quoting the latter's list of indications and technic. The essayist stated that the majority of the 60 or more recorded cases of vaginal cesarean section were for cancer of the uterus, but the number performed for puerperal convulsions is increasing rapidly, and this trouble will furnish the chief indication in the future. Most authorities agree that rapid delivery is the most important measure to reduce the mortality in eclampsia.

THE LIMITATIONS OF CESAREAN SECTION.

In a paper with this title Dr. E. Gustav Zinke, Cincinnati, analyzed 88 cesarean sections, reported by fifty-two different authors since January, 1900. Out of 81 mothers 66 lived, 81.5 per cent. But by excluding the deaths of 5 of the mothers which were due to malignant disease, death taking place two months, four months, one year and two years respectively after the operation, 71, not 66, mothers lived, and the maternal mortality was 12.34 per cent. Of the 90 children born, 56 lived, but excluding 13 cases in which the result as to the child has been omitted, and the cases of death before the operation, etc., the immediate fetal mortality is reduced to 25.26 per cent. When two years ago the author advocated the adoption of cesarean section for certain cases of central placenta previa, there was quite a marked opposition, and but few supported the speaker in his recommendation of the operation for this always alarming obstetric complication. Much has been said and written against it since, and still to-day nearly every new text-book on obstetrics and other recognized authorities on this subject admit that cesarean section may be justifiable under favorable conditions in the class of cases of a placenta previa then referred to.

DISCUSSION.

Dr. Charles S. Bacon, Chicago, believes vaginal cesarean section is undoubtedly of great value, not only for cancer, but also in cases where cesarean section is indicated for other reasons, when there is no contraction of the pelvis, and no sepsis, as, for instance, in cases of premature detachment of the placenta, a complication which defies all reasonable treatment. In placenta previa, however, there would be the same objection that has always obtained in regard to the typical operation. The other means of treating placenta previa are so perfect, so far as the mother is concerned, that it would only be in the case of a very competent operator, and in probably rare instances, that this operation or the typical one would be chosen. When we come to puerperal eclampsia, there is ground for either one of the operations. He believes that there is a future for the vaginal operation in cases of puerperal eclampsia, particularly those that are very carefully selected.

Dr. Walter B. Dorsett, St. Louis, narrated a case of successful vaginal section and delivery for placenta previa lateralis. He believes that possibly the operation is more applicable in placenta previa cases than in cancerous disease.

Dr. Frederick Blume, Pittsburg, asked Dr. Dorsett whether he would advise incision of the cervix in cases of six months' gestation with placenta previa, and whether he would practice it in every case.

Dr. Dorsett replied: Yes, judging by the experience I have had with this case.

DR. EDWIN RICKETTS, Cincinnati, advised administering veratrum before the anterior and posterior incisions are resorted to.

DR. J. HENRY CARSTENS said that when the gynecologist encounters a contracted pelvis, vaginal section is out of the question unless it is a case of five or six months' pregnancy. Where a woman has had a convulsion and then recovers consciousness, such a case requires premature slow delivery. If cancer is adherent to the pelvis, rectum and bladder, it requires cesarean section, as advocated by Dr. Zinke.

DR. RUFUS B. HALL, Cincinnati, emphasized the importance of early cesarean section to avoid infection, and cited a case in point.

DR. CHARLES L. BONIFIELD, Cincinnati, commended vaginal cesarean section in cases in which there is danger of infection in doing the suprapubic operation.

DR. JAMES F. BALDWIN, Columbus, Ohio, has made five, possibly six, cesarean sections since 1900 without maternal or fetal death. He heartily agreed with Dr. Zinke.

The Gilliam Operation.

DR. EDWARD J. ILL, Newark, N. J., has done Gilliam's operation 86 times, or in 68 per cent. of all cases operated on for retrodisplacements. There were no deaths; 51 cases have reported themselves as entirely well, 6 as markedly improved, and 4 as no better; 7 have become pregnant, and two have given birth normally; only 1 of the 4 reported as no better had a relapse of the malposition. This one was operated on again and an atrophy of the distal end of the round ligament discovered. Dr. Ill modified Dr. Gilliam's operation by not piercing the whole abdominal wall, fearing a weakness from which hernia might result. He separates the rectus abdominis from its anterior sheath and pierces the rectus muscle, the inner sheath, and the perineum, and progresses as taught by Dr. Gilliam, fastening, however, the round ligament to the posterior surface of the anterior sheath of the rectus muscle with chromicized catgut, thus leaving a strong fascia intact.

DISCUSSION.

DR. HERMAN E. HAYD, Buffalo, questioned whether it is necessary to open the abdominal cavity for uncomplicated retroversion. If there is a complicated condition, such as an adherent retroverted uterus, diseased tubes and ovaries, with probably diseased appendages, then it is all right to open the peritoneal cavity, although there is great danger attending it. It is not a question of mortality altogether, but of future complications, because as the result of opening this cavity adhesions will take place. He has been compelled to open the abdominal cavity and operate for obstruction of the bowels in three cases simply from an operation in which he had opened the peritoneal cavity and did conservative work on the tubes and ovaries.

DR. ALBERT GOLDSPOHN, Chicago, regarded the Gilliam operation as the next best thing to the Alexander for shortening the round ligaments, provided all of the indications could not be met through the inguinal canal. No operation, aside from shortening of the round ligaments through the inguinal canal, the so-called Alexander operation, had such a column of cases collected that had stood what he called the double test of pregnancy as had the Alexander.

DR. D. TOD GILLIAM, Columbus, Ohio, said that the results of pregnancy following this operation were gratifying to him as they must be to anyone who had adopted the method. He was receiving reports from medical men all over the country with reference to the occurrence of pregnancy after this operation, and with one or two exceptions the patients had passed through pregnancy without any more trouble than under ordinary circumstances.

Analysis of Common Causes of Death Following Pelvic and Abdominal Operations.

DR. JOSEPH PRICE, Philadelphia, said that post-operative complications and incomplete abdominal procedures perplex him more and more as he grows older, and give him the only mortality he now has in his cases. He told of operating on a case four months after an incomplete operation had been done in another hospital and finding a huge four-foot gauze towel anterior to the uterus. Post-operative sequelæ and deaths from gauze are very common. He is satisfied that they are thrice more common than from sponges. For a number of years he used sponges and valued them for clean work, for packing, or for a dry operation, and he believes viscera troubled him less than at the present time. He was then wholly ignorant of post-operative sepsis in his own work, and in that of his pupils. Had he now the time to take care of his sponges, he would go back to them, as highly as he values gauze. To his mind it is one of the most valuable materials in surgery. He spoke of the value of good nursing in the reduction of mortality rate.

A number of good operators attribute their low mortality wholly to the use of gloves. After adopting gloves he reduced his death rate to about nil, but his precautions were all redoubled. For example: After operating on a septic case, other operations were postponed for thirty-six to forty-eight hours.

Vaginal incisions and perforations favor a high mortality in later operations, made for the clean removal of the remaining pelvic pathology. Puriform tubes and ovaries, suppurating tubes and ectopic pregnancy seldom allow sufficient improvement in vital force and stamina to bear well the complete operation—suprapubic—after they have been incised through the vagina. Primarily they would all have been easy by complete methods and without mortality. The choice of method and material is of paramount importance to good work, and the suprapubic procedures, when complete and done early, drainage used when necessary, should, like the infrapubic, when done by one of the finished operators, like Jacobs, Segond or Pryor, give a mortality close to nil. He does a large number of vaginal hysterectomies for malignancy of the uterus, cervix or fundus, and for small fibroids without a death, and it is one of the easiest operations he is asked to do. In suppurative forms of tubal and ovarian disease he does not consider the vaginal route complete surgery, because the adherent omental and bowel adhesions and the diseased appendix are wholly neglected.

(To be continued.)

WASHINGTON STATE MEDICAL ASSOCIATION.

Fourteenth Annual Session, held at Spokane, Sept. 1-3, 1903.

The president, Dr. Charles McCutcheon, Tacoma, in the Chair.

Welcome.

About fifty physicians of the state were present at the opening session when Hon. W. F. Townsend delivered the address of welcome to the visiting members. The social features comprised a reception and dance at the Elks' Temple and a reception and musicale at the residence of Dr. and Mrs. N. Fred Essig.

Papers Read.

At the afternoon session of the first day papers were read by Dr. Guy S. Peterkin, Seattle, on "Acute Gonorrhea in the Male"; by Dr. Nathan M. Baker, Spokane, on "The Kidneys in Pregnancy"; by Dr. Park Weed Willis, Seattle, on "A Few Reasons for Early Operation in Gallstone Disease"; and by Dr. David DeBeck, Seattle, on "Rheumatic Chorioretinitis."

The second day was devoted to the reading and discussion of papers, prominent among which were "An Analytical Study of the Surgical Treatment in Prostatic Hypertrophy," by Dr. G. W. Hawley, Seattle; "Surgical Technic," by Dr. Elmer M. Brown, Tacoma; "The Pathology of Nephritis," by Woods Hutchinson, Portland, Ore., and "The Surgical Treatment of Bright's Disease," by Dr. Frantz H. Coe, Seattle.

A paper was read by Dr. Victor C. Vaughan, Ann Arbor, Mich., on "The Hygiene and Dietetic Treatment of Chronic Nephritis," which will appear in THE JOURNAL.

Typhoid Fever.

DR. VICTOR C. VAUGHAN, dean of the medical department of the University of Michigan, delivered an earnest and practical address, the central thought being that a pure water supply ensured to the state is better than anything else in the preven-

tion of typhoid. He urged his audience to see to it that its water supply is not contaminated. He said that the yearly deaths in the United States from typhoid fever numbered more than 50,000 and the cases more than half a million, causing an outlay estimated at more than $80,000,000. This sum, properly applied, said Dr. Vaughan, would forestall the appearance of the disease and would prevent many deaths and untold suffering now resulting from its ravages. He recommended that the Spokane officials secure absolute control of the water of the Spokane River and especially of that portion near the up-river plant. By so doing the city can control the water supply and ensure its purity. He dwelt on the contagious qualities of the disease and emphasized the fact that typhoid never appears except by infection, either direct or indirect, and that its prevention by careful watching of the water supply and other measures of less importance is far easier and better for the community than is disease eradication when it has once gained a foothold.

Resolutions Regarding Dr. Waughop.

The committee appointed for that purpose presented resolutions on the death of Dr. John W. Waughop, formerly of Chicago, who presided at the session held at Spokane in 1897, and who died on his way from Honolulu to the United States. The deceased was a prominent physician of Puget Sound, and had been a member of the state association almost from its beginning.

Election of Officers.

The following officers were elected: Dr. Frantz H. Coe, Seattle, president; Drs. William C. Cox, Everett, and George B. Wilson, Pullman, vice-presidents; Dr. James B. Eagleson, Seattle, treasurer; Drs. Elmer M. Brown, Tacoma, and Ralph N. Gordon, North Yakima, members of the judicial committee; Dr. Henry W. Dewey, Tacoma, delegate to the American Medical Association, and Dr. Robert L. Thomson, Spokane, alternate. Dr. Arthur H. Coe, Spokane, the secretary, has still two years to serve.

Next Meeting.

The invitation of the physicians of Seattle to hold the 1904 meeting of the society in that city was accepted.

ROCKY MOUNTAIN INTERSTATE MEDICAL ASSOCIATION.

Fifth Annual Session, held in Salt Lake City, Sept. 1-2, 1903.

The president, Dr. Charles H. Solier, Evanston, Wyo., in the Chair.

Welcome.

Gov. Heber M. Wells of Utah extended a hearty welcome to the society and paid an eloquent tribute to the medical profession. In the absence, on account of illness, of Dr. Alexander C. Ewing, Dr. Henry La Motte welcomed the association in behalf of the Salt Lake County Medical Society.

Program.

Among the notable papers on the program were a symposium on syphilis; papers on "Intubation" by Dr. Frank E. Waxham, Denver; "Treatment of Tuberculosis of the Lungs," by Dr. Edgar P. Hershey, Denver; "Operation for Chronic Nephritis," by Dr. Elias S. Wright, Salt Lake City, and "Volvulus of the Stomach," by Dr. Charles D. Spivak, Denver.

Banquet.

At the banquet held at the Commercial Club rooms about fifty physicians of the intermountain states were in attendance. Dr. Harry D. Niles, Salt Lake City, acted as toastmaster and toasts were responded to by Drs. Leonard Freeman, Denver, and Josiah N. Hall, Denver; R. Harvey Reed, Rock Springs, Wyo.; Donald Campbell, Butte, Mont.; Union Worthington, Salt Lake City; Samuel D. Hopkins, Denver, and Robert Levy, Denver.

Election of Officers.

The election of officers resulted as follows: President, Dr. Harry D. Niles, Salt Lake City; vice-presidents, Drs. Robert Levy, Denver, Colo., and T. J. McKenzie, Anaconda, Mont.; treasurer, Dr. Donald Kennedy, Denver; recording secretary, Dr. Henry La Motte, Salt Lake City, and corresponding secretary, Dr. George A. Moleen, Denver.

THE MEDICAL SOCIETY OF VIRGINIA.

Thirty-fourth Annual Session, held in Roanoke, Sept. 15, 16 and 17, 1903.

President, Dr. John N. Upshur, Richmond, in the Chair.

Welcome.

The first session of the society was held on the evening of September 15, when Mayor Cutchin, on behalf of the city of Roanoke, welcomed the visitors, and Dr. Merwin Branch, in behalf of the local profession, delivered the address of welcome. Dr. William S. Christian, Urbana, responded to the addresses of welcome in most pleasing style.

President's Address.

Dr. John N. Upshur, Richmond, devoted the greater portion of his address to reorganization. He referred to the report of the delegates from the society to the American Medical Association at the New Orleans meeting, and said that the society was now brought to the point where it would have to decide what action it would take regarding reorganization. The society had lived and prospered for many years and many of its older members were reluctant to see it relinquish any of its old landmarks. Still, the material interests of the profession and the future progress from a scientific standpoint demanded that the society should follow such a course as would not only increase its membership, but would give the profession of the state an influence in public affairs, especially those of a professional nature, and in the shaping of legislation which should make the organization a factor in the body politic to be not only felt but respected. Up to this time efforts to obtain legislation in matters of importance to the profession have met only such meager success as to be almost valueless, had been obtained by compromise or had been ignominious failures.

Report of the Delegates.

At the morning session on September 16 Dr. Stuart McGuire, Richmond, presented the report of the delegates to the American Medical Association. The committee states that the meeting was a great success, that the attendance was large, the scientific papers read of high order, the business of the Association satisfactorily transacted, and that the social pleasures were such as only New Orleans and her hospitable people could furnish.

Dr. McGuire then gave a summary of the principal proceedings.

Committee on Legislation.

Dr. George Ben Johnston, Richmond, made the report for this committee, endorsing the laws of the state governing the practice of medicine, which was enthusiastically received and a rising vote of thanks tendered the committee, which was instrumental in having passed the so-called "osteopath" bill.

New Constitution.

A great part of the time of the society was taken up by a spirited discussion on the adoption of a new constitution. This discussion, which was begun at the morning session of the second day, consumed the entire session of the afternoon and evening. Final action was postponed until the session of next year.

Advertising.

At its evening session the society decided that physicians might place business cards and advertisements of private hospitals in the newspapers.

Judiciary Committee.

Dr. Oscar Wiley, Salem, chairman of the Judiciary Committee, reported regarding Dr. Bittle C. Keister, Roanoke, that his course in advertising his residence and the diseases he treated has not been in keeping with the spirit of the principles of ethics. As regards Dr. William H. T. Shackford,

Walkerton, the committee found that he had not been a member of the society since 1890, and they therefore had no jurisdiction. The charges of contract practice against Dr. H. L. Tutwiler, Singerglen, were sustained, he acknowledged his error and promised not to offend again.

Election of Officers.

At the afternoon session the following officers were elected: President, Dr. Joseph A. Gale, Roanoke; vice-presidents, Drs. William E. Anderson, Farmville, S. T. Anderson Kent, Ingram, and Israel Brown, Norfolk; recording secretary, Dr. Landon B. Edwards, Richmond (re-elected); corresponding secretary, Dr. John F. Wynn, Richmond; treasurer, Dr. Robert M. Slaughter, Alexandria; orator, Dr. William S. Gordon, Richmond, and delegate to the American Medical Association, Dr. George Ben Johnston, Richmond. Richmond was selected as the next place of meeting.

Entertainment.

The social features offered by the Richmond physicians included trips to Bedford and the Palisades of the New River, and to Fries, a reception given by Mrs. T. E. Lewis to the wives and daughters of the members, and a trolley ride, and a reception at the Country Club, also for the ladies. The annual banquet was held at the Hotel Roanoke.

Presentation.

Dr. John N. Upshur presented an ivory and ebony gavel to the society and Senator Harvey was presented with the pen with which Governor Montague signed what is popularly known as "The Osteopath Bill."

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Chronic Purulent Otitis Media.

The following combination is recommended by *Bul. Med. de Nantes* as local treatment for chronic otorrhea:

℞. Resorcin ..... gr. xx 1 | 20
Tinct. opii ..... gtt. xv 1
Aq. destil. ..... ʒii 8

M. Sig.: A few drops to be introduced into the ear.

The ear should be thoroughly irrigated with a warm boric acid solution and dried with absorbent cotton. A few drops of the foregoing solution is then dropped into the ear and allowed to remain a few minutes.

According to Dench, in his treatise on "Diseases of the Ear," there are two objects aimed at in the treatment of chronic purulent otitis media:

1. To stop the discharge.

2. To relieve the subjective symptoms and to improve the hearing.

In order to accomplish these results the ear must be kept clean by irrigation. In irrigating the ear the patient must be carefully instructed as to the method of syringing or all the pus will not be removed. The ear should be drawn upward and backward, thus straightening the auditory meatus. The syringe should have a blunt nozzle, rendering it impossible to be carried into the ear far enough to do injury to the membrana tympani. The syringe should be directed downward and forward toward the tip of the nose. The fluid should be injected with moderate force and the temperature of the solution should be carefully observed, for if it is either too hot or too cold pain will be produced; so the patient should be the guide in choosing the proper temperature. Not less than one pint should be used at each irrigation. The author advises a 1-5,000 bichlorid solution, a saturated solution of boric acid or a 2 per cent. solution of carbolic acid. The patient should be instructed to wipe out the ear with small pledgets of cotton twisted about a small toothpick or metallic holder. He condemns the use of powders, as crusts may be formed and act as barriers to the outflow of pus. In the hands of experienced physicians, he states, astringent or stimulating powders are of value, especially after the discharge has greatly reduced and only a small amount of moisture remains. In such cases the insufflation of boric acid, zinc oxid, iodoform, or a mixture consisting of equal parts of alum and boric acid is of great service in entirely checking the secretion. Only a minute quantity must be used. If pain should again arise, the patient must be instructed to again syringe the ear and to follow out the same procedure if the discharge should set up again. If granulations form they may be touched up with chromic acid or silver nitrate fused on a metal probe. The use of chromic acid for this purpose is preferred.

In using the bichlorid solution some authors prefer the following combination in the treatment of otorrhea:

℞. Hydrarg. bichloridi ..... gr. ss | 03
Acidi tartarici ..... gr. xx 1 | 30
Aquæ ..... ʒiv 120

M. Sig.: To be used as a wash for the ear.

The powerful toxic character of the bichlorid should be remembered and care exercised in its use, no matter what strength solution is used.

In cases of moist eczema of the external auditory passages the following is recommended:

℞. Alumenis (burnt)
Amyli, āā ..... ʒii 8
Zinci oxidi ..... ʒss 2

M. Ft. pulvis. Sig.: To be used locally on the affected parts.

The following combination containing carbolic acid is recommended in the treatment of otorrhea:

℞. Acidi carbol.
Plumbi acetatis, āā ..... gr. x | 65
Tinct. opii ..... ʒii 8
Aquæ ..... ʒviii 240

M. Sig.: Warm the mixture and irrigate the ear twice daily; or:

℞. Acidi carbol.
Zinci sulph.
Plumbi acetatis, āā ..... gr. x | 65
Aq. destil. ..... ʒviii 240

M. Sig.: Inject into the ear night and morning.

Facial Acne.

In the treatment of acne of the face, according to *Médicine Moderna*, hot water should be applied locally, after which the following applications should be employed:

℞. Hydrarg. bichloridi ..... gr. viiss-xv | 50-1.00
Eau de cologne ..... ʒviii 240

M. Ft. lotio. Sig.: Apply locally.

And as an ointment or cream the following is recommended:

℞. Aq. rosæ ..... ʒss 2
Lanolini (anhydrous) ..... ʒiss 6
Aquæ ..... ʒiiss 10

M. Sig.: Apply locally.

Laxative Combinations.

The *Presse Médicale* recommends the following combinations as serviceable remedies in correcting constipation in adults:

℞. Extracti frangulæ flu.
Extracti cascaræ flu. āā ..... ʒvi 24
Glycerini ..... ʒiii 12

M. Sig.: One or two teaspoonfuls at bedtime; or:

℞. Ext. cascaræ ..... gr. 3/4 | 05
Podophyllin ..... gr. 1/7 | 009
Ext. hyoscyami ..... gr. 1/7 | 009
Euonymin ..... gr. 3/7 | 025
Pulv. saponis q. s.

M. Ft. pil. No. i. Sig.: One or two such pills at bedtime; or;

℞. Euonymin
Podophyllin, āā ..... gr. 3/10 | 02
Ext. hydrastis Canaden.
Pulv. saponis, āā ..... gr. ss | 03

M. Ft. pil. No. i. Sig.: One such pill at bedtime.

Chorea.

The following combinations are of value in the treatment of chorea, according to Yeo in his *Clin. Ther.:*

℞. Asafetidæ .....gr. xx | 1|30
Ext. valerianæ .....gr. xx | 1|30
Zinci oxidi .....gr. x | 65
Ext. belladonnæ .....gr. ii | 12

M. Ft. pil. No. xx. Sig.: One or two, night and morning; or:

℞. Ferri reducti .....gr. i-iii | 06-.20
Quininæ sulph. .....gr. ii-v | 12-.30
Acidi arsenosi .....gr. 1/50 to 1/30 | 0012-.0020

M. Ft. cap. No. i. Sig.: One such capsule after meals three times a day.

As a hypodermic injection the following combination is recommended:

℞. Sodii arsenatis.....gr. iss | 09
Acidi carbol. .....m. iii | 20
Aquæ destil. .....ʒiiss | 10

M. Sig.: Five minims to be injected daily.

Cerebral Arteriosclerosis.

The following outline of treatment is recommended by an abstract in the *N. Y. and Phila. Med. Jour.* in the treatment of cerebral arteriosclerosis:

℞. Pulv. scammonii .....gr. vi | 40
Pulv. jalapæ
Pulv. gutta perchæ, āā.....gr. iiss | 15

M. Ft. chart. No. ii. Sig.: One powder at bedtime; the second to be taken in twenty minutes.

These powders should be taken every ten or fifteen days. In the meantime the following is advised:

℞. Pulv. aloes
Euonymin, āā .....gr. 3/4 | 045
Podophyllin .....gr. 3/20 | 01
Ext. hyoscyami
Ext. belladonnæ, āā.....gr. 3/40 | 005
Saponis q. s.

M. Ft. pil. No. i. Sig.: One such pill at bedtime.

During three weeks of the month the following should be prescribed:

℞. Pot. iodidi .....gr. xlv | 3
Aq. destil. .....ℨx | 300

M. Sig.: One tablespoonful twice daily after meals.

And during the remaining ten days the following should be substituted:

℞. Theobromin. .....gr. viiss | 50
Sodii benzoatis .....gr. iv | 25
Lithii carb. .....gr. iiss | 15

M. Ft. cap. No. ii. Sig.: Two such capsules night and morning.

Drug Eruptions.

The following division of drug eruptions is made by Pernet, according to an abstract in *Amer. Med.:*

1. Erythematous, papular and urticarial eruptions. They may be caused by atropin, arsenic, quinin, copaiba, antipyrin, chrysarobin or mercury and iodoform locally. The diagnosis, according to the author, is not easy. From scarlet fever the differentiation is made chiefly by the mode of onset, the examination of the urine and the absence of corroborative symptoms. Multiformity of lesions is rather in favor of drug origin. The existence of a disease likely to be treated by one of the foregoing drugs, as gonorrhea (copaiba), headache (antipyrin), should be inquired into.

2. *Vesicular* and *bullous* lesions may be caused by antipyrin, quinin, arsenic, salipyrin, or the salicylates and less often by morphin, chloral or mercury. Iodids rarely cause bullas unmixed with pustules.

3. Pustular eruptions are most commonly due to bromids or iodids. The bromid rash has frequently been mistaken for syphilis. It must be remembered that bromids are found in many of the proprietary remedies,

4. Purpuric rashes may be caused by those drugs mentioned in the first paragraph.

5. Pigmentation is caused by arsenic, especially on those parts of the body not exposed to the air. [It is occasionally observed in cases of chorea treated by arsenic.]

The coal tar preparations have also been known to produce a permanent pigmentation of the skin. The silver salts may produce a blue discoloration.

Medicolegal.

Ten Thousand Dollars for Loss of Left Hand.—The Court of Civil Appeals of Texas says, in Texas & Ft. Smith Railway Company vs. Hartnett, that it has not been able to find a single case where damages have been adjudged any one in the amount assessed by the jury in this case, namely $15,000, for the loss of the left hand, and it holds $10,000 to be full compensation to a locomotive engineer for such loss and the physical and mental suffering incident thereto.

Answers of Applicant for Insurance as to "Serious" Illness.—The Court of Civil Appeals of Texas says, in Supreme Ruling of the Fraternal Mystic Circle vs. Crawford, that it seems to it that the answer of an applicant for life insurance on his own life that he has never had any serious illness should be considered as a mere expression of opinion as to the character of the sickness, and should not avoid the policy, even though such answer was untrue, provided, of course, the applicant did not know of its falsity. The form of the question necessarily calls for an opinion, and an agreement to warrant the truthfulness of the answer is no more than to warrant that the applicant will make a bona fide answer as to his opinion of the character of his ailment.

Indictable Conspiracy to Get Examination Questions.—In the case of the State of Washington vs. James G. Stewart and O. V. Lawson, the Supreme Court of Washington holds that a cause of action was stated by an information which alleged that these parties conspired to obtain from a member of the State Medical Examining Board a set of questions to be propounded at the ensuing examination for a consideration in money ($600); Stewart, it was agreed, was to prepare the answers and to deliver the questions and answers to Lawson, and it was understood that Lawson would thereby be enabled to fraudulently pass the examination, and would obtain from the board a license entitling him to practice medicine and surgery under the laws of the state. There was the intent then and there, on the part of each of the accused, to defraud and injure the people of the state, etc. It was stipulated in the case to be conceded that no person charged in or connected with the conspiracy charged in the information applied to or obtained from any member of the board a set of questions agreed on by the board to be propounded at the next ensuing examination; that no such application was made by any such person for a consideration of money or otherwise; that no member of the board was approached on the subject by any such person. The proof showed that Lawson and Stewart dealt with each other through an intermediary, one Braid. Stewart represented to Braid that he would obtain these questions and answers from one Dr. Wilson, whom he represented to be a member of the board. It developed during the trial that in all probability Wilson was a fictitious character. The Supreme Court holds that, so far as the stipulation was concerned, it could make no material difference whether the questions were obtained from the board or not, or whether they were obtained at all or not, as the offense charged was the unlawful agreement to so obtain them. It says that it appeared plainly from the testimony that the intent of the accused was to unlawfully obtain for Lawson the certificate or license desired. The crime was completed when they entered into the agreement to defraud the state medical board in the manner proposed. Neither the character nor the proper definition of a crime is dependent on the success or failure of the enterprise. Nor did it make any difference that Lawson thought that the medium through whom the questions and answers were to be obtained was Wilson instead of Stewart, or even that he thought that the name of the man with whom he was conspiring was Wilson in-

stead of Stewart. The two men actually arranged the terms and conditions of the unlawful combination through the aid of the go-between, and they were as responsible as though they had dealt with each other in person. Accepting the definition of the accused, that to constitute an indictable conspiracy there must be a combination or agreement of two or more persons to commit some act known or recognized as an offense punishable as a crime or prohibited under penalties of statute, or there must be a combination and agreement between two or more persons to accomplish a lawful purpose by unlawful means, the court thinks the information and proof were sufficient. For, it says, while it was not unlawful to pass the medical examination or to attempt to pass it, the information alleged, and the proof showed, that the accused conspired together for the purpose of assisting Lawson to do a lawful thing in an unlawful manner. While not unlawful in its nature, it was unlawful in respect to the means to be used in accomplishing it.

Evidence of Inability to Bear Children Inadmissible.—In the case of Ricards vs. the Safe Deposit & Trust Company of Baltimore, where a childless couple, the wife aged 53 years and the husband several years younger, sought to have a property trust terminated in which any child born to them would have an interest, the Court of Appeals of Maryland was confronted with what it characterizes as the serious and delicate question of whether it was competent for the parties to prove by medical testimony that the wife was incapable of bearing children. The court says that there are some early English cases which upheld or sanctioned a presumption that a woman of this one's age was incapable of bearing children. The more modern English cases have not adopted or relied on this presumption. In Lawson on Presumptive Evidence, p. 302, it is said: "In a number of cases the English courts have acted on the presumption that a woman beyond a certain age is incapable of child-bearing. No case can be found in the American courts in which such a presumption has been given effect to." At best, such a presumption is speculative. It is, as the very term "presumption" implies, a mere inference and not a certainty; and it would be exceedingly unsafe to permit property rights to depend on so precarious a basis. But the proposition here went further. It did not contemplate reliance on a simple presumption. Physical conditions had been testified to by medical witnesses who had expressed the opinion that there was no possibility of the life tenant being the mother of children. Can such evidence be received in a court of justice to affect the devolution of property, or to divert the course marked out for it to follow? The admission of such evidence in a case like this, where the avowed purpose of the proceeding is to cut out or strike down an estate in remainder, would or might be productive of most disastrous results. If, because of physical degeneracy, atrophy or decay, a medical man may, in a controversy involving title to an estate, testify that a woman is incapable of bearing children so that a trust deliberately created for her benefit during her life only may be brought to an end, with a view of vesting an absolute interest in her, or so that the vesting of a remainder may be accelerated, no one can foretell to what lengths such a precedent would lead. A surgical operation extirpating the uterus, for instance, would make it absolutely certain that no issue could be borne. If proof like that here under consideration were admitted, on what principle could evidence showing that an operation of the kind indicated had been performed be excluded? And, if not excluded, what would prevent interested parties from resorting to such or similar operations, if by a resort to them a mere equitable life estate could be converted into an absolute interest? It is wholly immaterial whether the inability to bear children arises from natural or artificial causes. It is not the cause, but the fact, that alone controls the question, and the single fact to which the law looks is death. On a case of first impressions, as this case is, the court goes on to say that it is bound to examine and weigh the results that may lie beyond the narrow horizon of an isolated controversy, and to consider the moral aspects of the situation, in reaching a conclusion which, when reached, may be fraught with such dangerous and demoralizing consequences. It is obviously not the province of courts of justice, and especially courts of equity, to encourage in any way a resort to a method like this for defeating a settlement or terminating a trust. If the evidence set out in the record should be received, no line could be drawn restricting or marking its limits, and no satisfactory reason could be given for the exclusion of the other species to which allusion has been made; and, if the latter sort of evidence be admitted, a court of conscience would be made the instrument for the promotion or encouragement of acts most manifestly subversive of good morals. And the court says that even had the question as to the admissibility of this kind of testimony been decided in other jurisdictions adversely to the view it takes, it should feel constrained, on grounds of a sound public policy, to exclude the testimony in a contention like this.

Titles marked with an asterisk (*) are abstracted below.

New York Medical Journal.

September 19.

1 *The Pathology and Treatment of Rheumatoid Arthritis. Edward M. Merrins.
2 *Birth Palsies. M. H. Bochroch.
3 The Results of Brain Surgery in Epilepsy and Congenital Mental Defect. (To be concluded.) William P. Spratling.
4 *Some Anatomical Varieties of Inguinal Hernia. George R. White.
5 The Etiology and Treatment of Subacute and Chronic Catarrhal Affections of the Upper Air Passages in Children. James A. Patterson.
6 *Observations on 100 Cases of Gastrointestinal Diseases Treated at the French Lick Springs. George D. Kahlo.

1. **Rheumatoid Arthritis.**—Under this head Merrins understands a constitutional polyarthritic disease, most frequent in women, commencing at the periphery and advancing symmetrically towards the trunks, accompanied with irregular fever, pain, anemia, vasomotor disturbances, deranged reflexes, muscular atrophy, tremor and cramps, and in children with splenic and lymphatic enlargement. Recent investigations indicate that the trouble is first in the synovial membrane, accompanied with effusion, then involving the capsule of the joint with erosion of the bone, contraction of fibrous tissue and rarefying osteitis. Ankylosis is usually fibrous, but may be bony. The etiology seems sometimes to have been a rheumatic attack, but more often follows some acute infectious disease, menstrual disturbances, absorption of toxins, cystitis and especially nervous depression. He thinks it is a condition due to toxins liberated in the system, not from a single germ, but from many infections, with impaired nervous vitality as a dominating predisposition. The germs and toxins which produce the arthritis exert at the same time a selective poisonous action on the nervous system. It occurs more frequently in persons with the rheumatic diathesis or with nervous systems that have been impaired by physical injury, shock, worry or anxiety. The history and general clinical aspect point to chronic poisoning rather than to the direct action of a specific germ. There are a few cases closely resembling rheumatoid disease which seem to depend wholly and directly on some functional or organic disorder of the nervous system, since they can not be traced to any source of infection. The treatment consists in removal of all sources of toxic absorption and the elimination of poisons from the system by baths, etc., the administration of medicines which check intestinal fermentation and the repair of the ravages of the disease by a liberal diet and restorative and tonic medicines. In extreme cases surgery is advised to obtain movement in the ankylosed limb. For the relief of pain he suggests the use of heat by salt or sand bags, the use of liniments, blisters to the spine or cold applications and, as a last resort, drugs. In the early stages much can be done to arrest the disease and bring about recovery. Later it is very intractable, but much can still be done to relieve the patient.

2. **Birth Palsies.**—Bochrock remarks that in spontaneous labor we should not be in too great haste to deliver the trunk, and traction on the head should not be made except in case of

necessity. If the axilla is hooked traction should be mild. In forceps extraction, expression should be used and one should remember the Walcher position and bring the forceps not far outside the direction of the axis of the body. Slight pendulum movements may be used, but extreme ones avoided. During extraction by means of the feet, the arms should be quickly attended to, in case they are interfering, by the Mauriceau procedure; resorting in grave cases to expression, and, if necessary, to Walcher's position. If the extraction of the head offers considerable difficulties, it is an indication for the application of forceps to the aftercoming head to avoid stretching of the axillary nerves. The treatment of brachial palsies may be both surgical and medical. In some cases where the nerves are torn, suturing should be indicated, though whether it can be carried out is a question. Treatment of brachial palsy once established resolves itself into the use of massage and electricity. In some cases the paralysis disappears, but this is not the rule when the condition is marked. The arm should not be allowed to hang helpless at the side, but should be supported in a sling or a Velpeau bandage.

4. **Hernia.**—White describes the different forms of inguinal hernia depending on the condition of the peritoneal diverticulum, whether closed or not, such as congenital hernia when the tunica vaginalis remains patent; congenital funicular hernia when the middle of the canal is closed but not obliterated; infantile or encysted hernia when a pouch of the peritoneum from the abdominal cavity is pushed down into an abnormally large cavity of the tunica vaginalis, and the ordinary acquired hernia.

6. **Gastrointestinal Diseases.**—Kahlo describes the effects of the waters of the French Lick springs at West Baden on gastrointestinal diseases. He finds the best results in chronic gastritis with deficient secretion and excessive mucus, also in cases complicating hepatic cirrhosis and nephritis, except in one case where there was evidence of marked renal degeneration. Myasthenia and hypersthenic gastritis are not so well affected, but are not contraindications. The majority of purely nervous myasthenics were benefited, probably due as much to the environmental and hygienic influences as to the water. Colitis of the mild type with constipation showed considerable improvement. Constipation due to atony was markedly improved. In enteritis of the severe type he does not think the waters indicated. He has seen albuminuria and glycosuria disappear in some cases, but he can not say as to the duration of the cure. Persons should exercise freely while drinking the water. It should be taken not less than one hour before or two hours after meals. It is also important to obtain a complete evacuation of the bowels early in the treatment. He gives analyses of the different springs and a description of the accommodations. The diet should be regulated. Alcohol is naturally contraindicated and he warns against the overuse of the waters.

Medical Record, New York.

September 19.

7 *Differential Leucocyte Count in the Early Days of Typhoid Fever. Henry A. Higley.
8 A Case of Leucosarcoma of the Choroid. Thomas R. Pooley.
9 The Range of Osteoplasty as an Aid in the Conservative Surgery of Bone Traumatism. Thomas H. Manley.
10 *Some of the Mistakes We Have Inherited. Mark I. Knapp.
11 Early Symptoms of Dementia Precox. A. R. Diefendorf.

7. **Typhoid Fever.**—Higley finds that many cases of typhoid fever, contrary to the common notion, showed a characteristic differential leucocyte count within the first week of the disease. The value of the differential leucocyte count in the early diagnosis of typhoid is as yet a question, but it seems certain that when used in addition to the total leucocyte count more information may be obtained than by employing the total count alone. He gives blood counts of a number of cases of malarial fever and reports in some detail the counts and reactions in several cases of typhoid.

10. **Mistakes We Have Inherited.**—Knapp questions whether vomiting is ever a reflex phenomenon, and considers it always due to gastric irritation, the direct cause always lying within the lumen of the alimentary canal, no matter what outside cause there may be. Green vomit in the majority of cases does not mean bile but the growth of green mold, and chocolate-colored vomit need not necessarily mean blood, but may mean red mold. Of course, either of these may coexist with bile or blood. Another mistake he calls attention to is trusting too much to the appetite as a sign of healthy gastric conditions, and still another is the dietetic value of stale bread. It is not the freshness of the bread that harms, but the quantity. Too much is taken. Constipation from dietetic causes is noted as a condition in regard to which we have erroneous views. We are inclined to prescribe too much fruit, whole-wheat flour, sweets, etc., in these cases. They are liable to produce gaseous fermentation and irritation and may be decidedly injurious and help to produce organacidia gastrica or organacidia enterica, which he proposes later to describe. What may be beneficial in small quantities becomes absolutely dangerous when taken in large amounts, and once recommended they are liable to be taken in excess.

Medical News, New York.

September 19.

12 *The Etiology and Chemical Pathology of Gallstones. C. A. Herter.
13 *The Modern Treatment of the Acute Suppurations of the Knee Joint. Arpad G. Gerster.
14 *What Ought We to Expect from Cardiac Drugs in Heart Weakness. O. T. Osborne.
15 *A Study of Good Results in Hip Disease. V. P. Gibney.
16 *Chronic Nephritis without Albuminuria. Arthur R. Elliott.

12.—See abstract in THE JOURNAL, xl, p. 1598.

13. **Suppuration in the Knee Joint.**—Gerster describes the different forms of gastric suppuration, metastatic or pyemic, that due to osteomyelitis and traumatic suppuration. He speaks very highly of the Mayo incision as the best method for reaching and draining the parts, especially in osteomyelitic cases.

14. **Cardiac Drugs.**—Osborne describes the various cardiac tonics, naturally putting digitalis in the first place. He thinks it is, as a rule, indicated in chronic cardiac weakness, except when due to myocarditis or fatty degeneration. In acute endocarditis complicating acute rheumatism it is hard to say whether it should or should not be used, but its slowing of the heart is likely to do good. In the feeble heart of myocarditis it is a question whether it is to be used. We should not deny the patient the possible benefit where it seems to be of value, though its action should be closely watched. It should not be used in endarteritis or atheroma, and ordinarily not in aneurism. It is often a good soporific in the insomnia of neurasthenia. No fixed rule can be given as to its use in renal inflammation. It is of benefit in the anemic edema of the lower extremities and effusion without kidney lesions, and in chronic liver disease it is always of benefit combined with other treatment. In uremic poisoning or low vasomotor tension with weak heart, digitalis should be cautiously tried. If it does not give good results in 36 to 48 hours it should be stopped. Its contraindications are high tension of the arteries, atheroma, weak cardiac muscle and ordinarily a serious kidney lesion. The best substitute for it is strophanthus, which can be used when a cardiac tonic is needed, and digitalis produces nausea and vomiting or the blood pressure is high, and when a rapidly acting tonic is desired, when there is more nervous irritability and heart weakening than actual muscular debility or incompetency, and in children who are very susceptible to digitalis. Spartein sulphate is a substitute for digitalis, which can be used in case of irregularity and nervous irritability of the heart with general nervousness. Muscle or fatty degeneration of the heart, low pulse tension and dilatation or cardiac weakness contraindicate it. Cactus does not increase the cardiac strength as does digitalis, but has no cumulative action and does not wear itself out. Convallaria and adonidine have been unsatisfactory in his experience. Suprarenal acts as a vasomotor and cardiac stimulant only when absorbed from the nose or mouth, not by the stomach. Strychnin Osborne considers overused at the present time, but he speaks highly of caffein, as a cardiac, cerebral and muscular stimulant and as a diuretic and an antidote in poisoning. Its contraindications are palpitation, irritable heart, high blood pressure, cerebral or spinal inflammations or irritations, in-

somnia, neurasthenia and acute genitourinary inflammations. As to alcohol, he thinks in small doses it may be of value in relieving the heart by its vasodilator action, though too large doses are contraindicated. It should be given concentrated. To combat continuous cardiac failure or depression, alcohol is the poorest stimulant we can use and exaggerates the depression. He has also obtained as good circulatory results in sthenic fever from small doses of nitroglycerin as he has from alcohol. The narcotic effect of the latter in certain serious feverish conditions may, however, be of advantage.

15. Hip Disease.—Gibney discusses what are and are not good results in these conditions, and thinks that we should seek for the best results, that is, as full a restoration of function as possible. Where the treatment has been too long delayed and the head and neck of the femur have suffered severely, fair results may be obtained by attention to details, though fine results are hardly to be expected. In the later stages we have to be content with correcting the deformity and eradicating necrotic areas and sinuses. Results that will satisfy can be obtained if we maintain the best position of the limb.

16. Chronic Nephritis Without Albuminuria.—Elliott reports cases and points out that chronic interstitial nephritis may have latency of symptoms through the entire course of the disease, though this is most likely in the early stages. It does not constitute a point of absolute distinction between the early and advanced stages or between the mild and severe forms. Albuminuria is very frequently absent during the early stages and may be up to the end or through the entire course of the disorder. It is a very unreliable diagnostic sign. More dependence can be placed on the diminution of urinary solids and especially on the presence of casts. Chronic interstitial nephritis never exists as a clinically recognizable condition without casts in the urine. The secondary circulatory changes following the disease are so characteristic as in most cases to furnish ground for its recognition before the urine is examined. The inconstancy of the urinary symptoms puts them much in the same diagnostic category as murmurs in valvular heart disease.

American Medicine, Philadelphia.

September 19.

17 *Labia Urethræ and Skene's Glands. (Concluded.) Howard A. Kelly.
18 *The Rational Treatment of Pulmonary Tuberculosis, with Report of Cases. F. M. Pottenger.
19 *The Treatment of Chronic Round Ulcer of the Stomach. Frank H. Murdoch.
20 The Bacillus of Syphilis. Justin DeLisle.
21 *Placenta Previa and Its Treatment, with Special Reference to Combined Version. Daniel Longaker.
22 A Contribution to the Prophylaxis of Venereal Diseases. G. Morgan Muren.
23 English Surgery as Practiced by Richard Wiseman, Sargeant Chirurgeon, in 1676. John D. Singley.

17. Labia Urethrae and Skene's Glands.—Kelly's article is finished in this issue. He thinks he has made clear the following points: 1. That one often finds definite labia overlapping the urethral orifice. 2. That their function is protective and in part sexual. 3. That attention must be more regularly directed to Skene's glands. 4. That these structures are veritable glands (Schüller). 5. That their function is to lubricate the labia urethræ and is also largely sexual. 6. He calls attention to the simple method of constructing a hairpin speculum to expose the orifices of these glands, and 7, presents a simple and safe method of injecting them, a decided improvement over the hypodermic syringe. 8. He also calls attention to 2 cases in which smegma bacilli in large numbers were lodged in the glands.

18. Pulmonary Tuberculosis.—Pottenger insists on the value of pure, moderately dry, aseptic air, a maximum of sunshine, freedom from storms, a dry porous soil, a liberal diet with a maximum of nourishment, and a minimum expenditure of digestive energy. The use of hydrotherapy, especially the cold morning rub, is also advised with regulated exercise and a general regulation of the habits of life. He thinks serum therapy in this disease is of decided value and increases the patient's chances of cure at least 20 per cent. Direct medication of the air passages, while it can not be considered curative, in many cases alleviates symptoms. He mentions intratracheal injections of menthol, olive oil, camphor and iodoform or izal from 1 to 10 per cent. in Price's redistilled glycerin. The pneumatic cabinet is also mentioned as a useful adjunct of treatment. Drugs are of secondary importance, but for the correction of symptoms cinnamic acid seems to him of some little benefit, though his experience is limited. Ichthyol apparently facilitates expectoration and aids digestion in some cases. Creosote and creosotal he only uses for intestinal putrefaction, and he also employs creosotal in pneumonia. Aside from this his drugs are mainly stomachics, intestinal antiseptics and general tonics where they are indicated. He gives his results in detail.

19. Gastric Ulcer.—Murdoch thinks that women suffering from gastric ulcer require absolute rest in bed, and if this is impossible they should dispense with corsets and tight waistbands and keep as quiet as possible. Men, on the other hand, with chronic gastric ulcer do not ordinarily require rest, and manual laborers even get along without quitting their work. Brain workers must be relieved of their mental work and worry, at least during the early months. The condition of the gastric secretion must be looked after unless there are other reasons than the ulcer for not passing the stomach tube. If free or normal hydrochloric acid is found milk must form the principal article of food and be given with other liquid foods. He speaks well of bismuth and silver nitrate in chronic gastric ulcer when there is hyperchlorhydria or achylia. This last probably acts by producing a thin film of coagulated albumin over the inflamed and sensitive mucous membrane around the sore. He does not believe in discontinuing the liquid diet until epigastric tenderness has disappeared, the time varying from four weeks to very much longer periods. The complications of hemorrhage and perforation are noted. In the former he advises absolute rest in bed, ice, either by the mouth or rectum, an ice bag applied to the epigastrium, and nourishment should be given by the bowel. In case these are insufficient, gelatin injections by the mouth and adrenalin are suggested. In persistent hematemesis Ewald's recommendation of washing out the stomach with ice water should be tried, but if all these fail, operation should be considered.

21. Placenta Previa.—Longaker reports 11 cases treated by the plan of combined version first introduced by B. Hicks with the result of 6 babies born alive. He thinks we do well in these cases not to hurry the birth after turning.

Boston Medical and Surgical Journal.

September 17.

24 The Ill Health of Francis Parkman. George M. Gould.
25 *Minor Surgery in Country Practice. Clifford S. Chapin.
26 *The Dietary Treatment of Constipation. Henry F. Hewes.
27 Hyperchlorhydria. Roscoe W. Swan.
28 A Mastoid and Auricle Retractor. Frederick L. Jack.

25. Minor Surgery in Country Practice.—Chapin suggests the importance of a thorough knowledge by the country practitioner of bandaging aseptically and antiseptically, and also the necessity of knowing how to do strapping and do it well. The advantages of understanding the technic of poultices and intravenous injection and infusion of saline solution are also mentioned. The necessity of the country doctor knowing something about the proper method of anesthetizing is important and he thinks is neglected. It is, moreover, essential for him to know how to meet hemorrhage and shock, and Chapin gives details. There are certain operations in which teaching has been deficient such as in the treatment of fractures. He insists also on a thorough knowledge of the management of strangulated hernia which is essential in emergencies.

26. Constipation.—The factors bearing most directly on the physiologic function of the intestines are enumerated by Hewes, such as the habit of a regular period of defecation, a proper amount of physical exercise and a proper diet. The physician must at the start advise as to these. The first two explain themselves. As regards the latter he points out the necessity of having a proper selection of foods containing sufficient unabsorbed residue, and gives a diet list for constipation. Fats may also be of use if taken in considerable quantity, and foods which contain or generate considerable quantities of organic acids which by their action on metabolism or the

nerve centers after absorption increase the intestinal activity, such as tamarinds, prunes, plums, etc., and certain vegetables. His patients were advised to give up drugs and are instructed as to exercise and the necessity of following a diet list made up according to the indications mentioned above, such as whole-wheat or rye bread, cabbage, beets, turnips or lettuce, and prunes or tamarinds for dessert. Enemata were used when necessary at the start. The diet was kept up from one to two weeks, and in some cases prunes stewed with senna were prescribed (1 ounce of senna leaves stewed with 3 or 4 dozen prunes). In some special cases a fat excess in the diet was prescribed. He says in the very large majority of cases of constipation the chief and possibly the only cause is failure to follow a normal physiologic manner of life. In such, a complete cure can be obtained by a proper direction of general régime and diet.

44 *On a Rapid Method of Staining Neuroglia. Roy McL. Van Wart.

36. **Hernia.**—In this paper Halsted calls attention to certain special points, such as excision of the veins, utilization of the right rectus muscle to close the lower part of the right inguinal canal and utilization of part of the cremaster muscle, which was formerly cut away. The illustrations explain almost better than the text, but the steps of the operation are given as follows: 1. Division of the aponeurosis of the external oblique and reflection of the flaps. 2. Splitting of the cremaster muscle and fascia a little above the center of the cord. 3. Freeing the internal oblique muscle as much as possible. Here it may be advisable to make relaxation cuts in the anterior sheath of the rectus muscle under the aponeurosis of the external oblique, but doing this after sewing of the internal oblique to Poupart's ligament is begun when the tension can be better gauged. 4. When the veins are large, as is usual, they should be excised with very great care to avoid even the slightest extravasation of blood, avoiding any handling of the vas deferens if possible. 5. Ligation of the sac by transfixion or purse-string suture at the highest possible point. 6. Use of the lower flap of the cremaster muscle and its fascia by drawing it up under the mobilized internal oblique, holding it in position by fine silk stitches, which, having engaged firmly a few bundles of the cremaster, perforate the internal oblique, preferably where it becomes aponeurotic and are tied on the external surface of the latter. 7. Mobilization of the internal oblique, possibly further release by incising the anterior sheath of the rectus muscle. 8. Overlapping of the aponeurosis of the external oblique muscle by the so-called Andrew's method. 9. Closure of the skin with a buried continuous silver suture and covering of the incision with five or six layers of silver foil. It is unnecessary to dress or examine the wound closed in this manner for two weeks, when the wire may be withdrawn. The patients are kept in bed from 18 to 21 days. If during the dissection of the sac the cord is torn from its bed and subjected to traumatism and the testicle withdrawn from the scrotum, the veins should not be excised. In such cases Halsted would advise the transplantation of the vein alone. In children the veins should not be excised, as the probability of atrophy is greater than in adults.

37. **The Pathology of Smallpox.**—Stokes reports and illustrates the findings in smallpox, which he summarizes as follows:

Although we have only studied five cases of smallpox at autopsy, yet some conclusions can be drawn from the work. The early skin lesions indicate that the primary infection in smallpox takes place in the lungs, probably by inhalation. The poison, when it enters the circulation, shows a selective influence on the epithelium of the skin and respiratory tract, and many cases are probably not further affected. The serious and fatal lesions of smallpox are caused by the secondary infection from the skin and respiratory tract, and the infectious agent is usually the streptococcus pyogenes. This organism is so distributed throughout the lesions as to explain most of the visceral changes, such as thrombosis, local necrosis and the various pulmonary changes. This streptococcic septicemia is the most striking feature of fatal smallpox, and if it were possible to overcome this condition by a special serum, the mortality from the disease would be greatly reduced.

39. **The Pancreas.**—Opie describes the anatomy and histology of the pancreas and calls attention in conclusion to the fact that the organ consists of two functionally diverse elements—on the one hand, cells which supply to the intestine important digestive ferments, and on the other hand, cells having no communication with the ducts of the gland, but an intimate relation to the blood vessels. In the second place, he also calls attention to the fact that the close anatomic relation of the pancreatic duct to the common bile duct favors transmission of the morbid processes from the liver to the bile passages and the pancreas.

43. **The Stomach Tube.**—Friedenwald points out that the invention of the stomach tube is to be credited to Dr. Philip S. Physick of Philadelphia, rather than to Jukes and Bush, who have been considered its inventors. He brings forward evidence and seems to make the case clear that Physick used the tube as early as 1800, and published the report of successful results with it in 1812, while the work of the English inventors first appeared in 1823.

44. **New Neuroglia Stain.**—Van Wart recommends the following process as a rapid method, possessing the advantages over the Mallory technic that it can be applied to any formalin-fixed tissue without prolonged special preparation and only requires a few minutes:

1. Fix in 10 per cent. formalin (4 per cent. formaldehyd). The tissue should be obtained within ten hours of death and fixed, preferably in small pieces. 2. Embed in paraffin (preferably the aniliin oil method). 3. Cut 5/15 micra sections and mount on slides in the usual way. 4. Remove the paraffin by means of xylol, absolute alcohol and 95 per cent. alcohol. 5. Cover the section with a saturated aqueous solution of picric acid for two minutes. The section should be of a deep yellow color. 6. Wash in water. 7. Cover the section with a 10 per cent. aqueous solution of ammonium bichromate for two minutes. The yellow color should be completely removed. If not, repeat. 8. Wash in water. 9. Stain five minutes in a mixture of 8 c.c. of crystal violet saturated solution in alcohol (95 per cent.) and 42 c.c. of aniliin oil water, made by shaking 5 c.c. of aniliin oil with 95 c.c. of distilled water and filtering. This solution should be freshly prepared. A similar solution of gentian violet or methyl violet may be used, but the stain is not so intense. 10. Wash in water and blot. 11. Cover a 5 per cent. solution of potassium iodid, which has been saturated with iodin, one minute. 12. Wash with water and blot until the section is dry. If all the water is not removed the differentiation will be imperfect in the portions containing water. 13. Differentiate in aniliin oil and xylol, equal parts. 14. Wash thoroughly in xylol. 15. Mount in balsam. The sections if not exposed to light will keep well. The portions of the section where the neuroglia is abundant are of a deep violet color. The rest of the section is nearly colorless. The method is based on that of Mallory.

51 The Action of Certain Ions on the Lysins in Human Serum. Ludvig Hektoen.
52 Network Formations in the Right Auricle, with Demonstration of a Specimen. E. R. LeCount.

45. **Blood Cultures in Pneumonia.**—Rosenow finds that with improved technic and the using of large quantities of blood for inoculation the pneumococcus can be recovered in all cases of pneumonia, and in obscure cases the blood culture may be a valuable diagnostic aid. The pneumococcemia in pneumonia does not mean a specially unfavorable prognosis. On account of the difficulties involved agglutination of the pneumococcus is at present of scientific, rather than of practical, value. Normal and pneumonic blood serum appear to have no bactericidal influence on the pneumococcus. His studies do not settle the question whether lobar pneumonia is the primary result of direct local infection or secondary localization in the lung.

46. **Pneumonia.**—From a study of 171 cases Kerr finds that the age of maximum frequency of deaths from pneumonia is from 35 to 40 years, while that of the greatest number from all causes is between 40 and 50. Fatal cases are somewhat more frequent in males. Unilateral cases predominate, the right side over the left and the lower over the upper lobe. Crossed pneumonia is rare. The majority of cases reach the stage of gray hepatization, and while abscess and gangrene are uncommon, pulmonary edema and bronchitis are frequent. Acute parenchymatous changes occur in the parenchymatous organs with marked frequency. The serous membranes are involved in the following proportion: pleuritis, 70 per cent.; pericarditis, 12 per cent.; endocarditis, 8 per cent.; meningitis, 6 per cent.; peritonitis, 5 per cent.; and arthritis, very rarely. Pericarditis occurred with pneumonia of the lower lobes in all but two cases, and of the right middle lobe in these two. The preponderance of vegetative endocarditis and the preference for the mitral valves in this series differs from the usual experience; the frequency of meningitis associated with endocarditis is also noteworthy. Jaundice in pneumonia does not seem to be accompanied by any uniform change in the liver. Kerr notes the importance of pneumonia as a terminal infection. The presence of chronic pathologic lesions in a large number of cases is remarkable. These are mostly of importance from a prognostic point of view.

50. **Fever Following Rat Bite.**—Evans has seen 3 cases of this fever, and has looked up the literature, finding 2 cases reported in European circles, while 15 appeared in American and 38 in Japanese journals. There are also slight references to others. He reviews the literature and analyzes the symptoms as they appear. The disease seems to come on late, in a large proportion of cases after a number of days, though the incubation period varies, and the duration of the fever may be weeks and months. The wound usually heals promptly. In general, after an interval of 10 to 21 days the fever appears, with pain, swelling and some discoloration at the point of bite. There is some chilliness and a general neuralgia and rather noticeable sweating. The peculiarity of the fever is its tendency to intermissions, which may last for days and weeks, and the patient feel well in the interval. Local glandular enlargement is marked; there may be a general adenopathy. Three deaths probably from this cause are recorded. The pathology, so far as known, is rather negative, except hyperemia of the cord and the increased cerebrospinal fluid in Miura's case. Suppuration either in the wound or glands has not been noticed of recent years under modern treatment.

56 *The Value of Ophthalmic Examinations in the Differential Diagnosis Between Typhoid Fever and Acute Miliary Tuberculosis. Clarence Loeb.
57 Buphthalmos in a Subject of Congenital Dislocation of the Crystalline Lens. F. W. Marlow.

54. **Epiphora in Basedow's Disease.**—This symptom is considered by Berger in the case he reports as a secretory neurosis of the lachrymal glands similar to the other secretory neuroses of Basedow's disease. He rejects the mechanical explanations that have been offered. If this theory is correct, of course sounds and astringent injections are useless. The best treatment is that which relieves the general symptoms as well as the epiphora, though in obstinate cases perhaps the internal use of atropin or local instillations of cocain might be tried. For annoying dryness of the ball he has suggested the instillation of sterile salt solution, which has been employed with good results.

55. **Endogenous Infection of the Eye.**—The important facts deduced from the investigations of Zalenkovsky and Woizechowsky, as mentioned on page 819, are that in experimental endogenous infection of the eye the vitreous is a more favorable soil for the propagation of bacteria that have gained entrance than the aqueous, but that the entrance of bacteria is effected with more difficulty. The bacteria circulating in the blood can enter the aqueous and the vitreous in the absence of all inflammatory, embolic, or thrombotic processes in the vessels of the eye; their trophic action on the vessel walls is sufficient to permit their passage, but these conditions favor it.

56. **Typhoid Fever and Miliary Tuberculosis Differentiated.**—Loeb reports a case of general miliary tuberculosis, and to some extent discusses the literature. He finds that tubercles occur on the choroid probably in at least 50 per cent. of the cases of general miliary tuberculosis, though their absence does not disprove the presence of the general process. When present, especially when the development can be followed with other characteristic symptoms, they are pathognomonic of general miliary tuberculosis, and in cases of supposed typhoid fever running an atypical course, especially when the Widal reaction is negative, the eye should be examined. The presence of tubercles may not affect the therapeusis, but there are cases where a correct diagnosis is important from the forensic standpoint as well as being otherwise satisfactory.

61½ Uterine Myomas. William H. Baker and W. P. Graves.
62 *Postoperative Cystitis in Women. G. Kolischer.

59. **Puerperal Infection.**—The conclusions of Boldt's article are given as follows:

> In the acute form of puerperal septicemia and pyemia in which it is probable that the general circulation has been invaded by micro-organisms, whether a bacteriologic examination of the blood at the time of making the examination proves this or not, no method of surgical intervention is of benefit; on the contrary, it is likely to shorten life. In all puerperal infections the form of surgical intervention, if one be indicated, must be left to the judgment and conscientiousness of the physician, and the prognosis will vary according to the condition to be combated. With our present knowledge no strict rule by which one should be governed can be laid down.

60. **The Bacteriology of the Puerperal Uterus.**—Marx concludes that the normal puerperal uterus is a sterile organ. The presence of bacteria in the absence of general evidence of constitutional disturbance, means the introduction of such bacteria by accidental contamination. Their presence in the uterus accompanied by fever means in all probability sepsis arising from the uterus. Their absence in the presence of general symptoms means that we should look to other organs for the source, such as the vagina or vulva or some general disturbance accompanying the puerperal condition. He holds that the genitourinary tract is at all times well protected in ordinary cases in healthy women and only the operator's hands

can be a source of infection. Intrauterine douches can not clear the uterus from infecting germs. The only way to do this is to cause firm contraction of the uterus and limit infection, together with the use of a remedy to aid rapid absorption, and which, by its antiseptic properties, will destroy the germs. For this purpose he finds firm packing with reliable iodoform gauze the best method.

61.—See abstract in THE JOURNAL, xl, p. 1530.

62. **Post-Operative Cystitis.**—This condition, especially when occurring after ureteral denudation, Kolischer thinks is probably due to nutritive changes causing a point of less resistance for the immigration of micro-organisms which probably come from the intestine. Trophoneurotic changes also appear probable at the end of a denuded ureter. It is important always to make sure of the condition of the bladder before operation, and to consider also the possibility of cystitis occurring some time after operation as not having anything to do with the latter but being due to other causes.

65 *Semilunar Cartilages; Their Anatomy and Surgery. H. A. Sifton.
66 Clinical Lectures on the Etiology, Pathology, Diagnosis and Treatment of Tumors. A. H. Levings.

64. **Pathogenesis of Locomotor Ataxia.**—Hassin's article on this subject is concluded in this issue. He finds that tabes dorsalis is the result of an affection of the posterior roots of the spinal cord; chiefly mechanical, due to compression on the part of the membranes of the spinal cord or of the brain. Its cause is everything that may produce meningitis, taking cold, sexual abuses and infectious diseases, chiefly syphilis. The treatment must be mechanical; surgical in those forms of tabes where it can be applied (tabes cervicalis, tabes dorsalis). Such treatment, if taken early, will stop further development. In studying the clinical forms of tabes, all the newest methods applicable in the study of meningitis must be applied: Kernig's symptom, cryoscopy, cytoscopy and hemolysis of the spinal fluid of tabetic patients. Hassin presents elaborate arguments in support of this view of the pathogenesis and urging the importance of the minutest microscopic examination of the spinal membranes and the brain and experimental research for better knowledge of the subject.

65. **The Semilunar Cartilages.**—Sifton has found comparatively little literature in regard to injuries of these bodies. Simple displacement of the cartilage in the knee would be often taken for sprain. The joint will usually be locked in a position somewhat short of complete extension. This symptom is not found in any other injury of the joint except in cases of a floating body which is practically the same as a loose cartilage. For treatment the cartilage should be reduced if possible; if it is torn loose it can not be reduced by any form of manipulation, but if it is only dislocated it can readily be replaced by fully flexing the knee, rotating it outward or inward and then quickly extending it. If the cartilage is prominent, pressure should be made on the prominent point, while manipulations are carried on. Any form of splint which can give the knee rest should be applied. After a week this splint should be removed daily for careful massage and passive movements. Eight to twelve weeks are required for the cartilage to become fixed after the first injury. Some cases, however, do not completely recover and are likely to get out of place again at the slightest provocation. Elastic knee bandages and braces are then worthless, and relief can be obtained only by operative measures, completely removing all detached or loose portions of the cartilage. The operation should be under the most careful asepsis. He describes his technic as follows, with the details of 2 cases operated on:

> The best form of incision for the removal of a semilunar cartilage is the U-shaped, with the convex border towards the patella. Turning the flap down to the required extent the joint is opened by a transverse incision above the upper surface of the cartilage. This incision should be made as far above the cartilage as possible, for the reason that there is a considerable artery immediately beneath the lower border which might be wounded if the incision was made close to the cartilage. I believe that the U-shaped incision of the skin and overlying tissues is much preferable to a straight incision, for the reason that it divides the resulting scar into three parts and is, consequently, more flexible than if all the tissues had been divided in the same line. If the incision is carried well forward it will not be necessary to interfere with the lateral ligaments, ample room being obtainable by running the cut well forward. By retracting the patella and manipulating the joint a good view of one-half of the knee is easily obtained. As above stated, I would not recommend, under any circumstance, an attempt to suture the cartilage, but would remove all the detached portion. This can best be done by a strong, narrow-bladed scissors. I think no fluid should be introduced into the joint unless considerable hemorrhage has been encountered and it becomes necessary to wash out blood clots which have accidentally obtained access to the cavity. The rule which should always be followed is to produce as little traumatism as possible and attain the object necessary. The joint should be closed by a continuous, fine catgut suture and the skin incision then closed. The limb should be put at rest by means of a plaster dressing for two weeks, at the end of which time, the wound being entirely united, gentle manipulation of the joint is commenced, the patient being also allowed to bear some weight on the leg.

July.

67 *The Iodin Reaction in Surgery. Conrad George.
68 *Pathologic Changes Following Lacerations of the Cervix. Ralph L. Morse.
69 *Displacement of the Pelvic Organs. James G. Lynds.

67. **The Iodin Reaction in Surgery.**—This reaction which has been known for over twenty years and with which the leucocytes of the blood contain granules showing a reddish-brown stain with iodin, has been studied by George. He finds as a general result of his investigation that the reaction alone and apart from a study of the history of the case is not of much value. It can be regarded as a symptom of a little more value than leucocytosis, but not as pathognomonic in any degree. The diagnosis of abscess or sepsis can only be made by a careful study of the reaction in connection with other symptoms, and no one symptom can be taken as an indication for operation.

68. **Cervical Lacerations.**—Morse reviews the pathologic changes of cervical lacerations, the variations in the columnar epithelium, stimulating it to proliferation, and the acid and infected vaginal secretions producing so-called erosions and probably favoring the occurrence of malignant disease.

69. **Displacement of the Pelvic Organs.**—Lynds holds that in a considerable proportion of cases, especially with a large, heavy, retroverted uterus with lacerated cervix and prolapsed and diseased appendages and the patient nearing the menopause, he would remove the organs. In younger patients he would amputate or repair the cervix and perform an anterior or posterior colporrhaphy as indicated, and strengthen the pelvic floor. Then, if necessary, he would perform a ventrofixation or shorten the round ligaments as seems best. In many cases, however, anterior fixation does not prevent a return of the prolapse. His experience has been that even in partial procidentia the greater amount of the suffering is only partially, if at all, removed by the internal shortening amputation and operation on vagina of the organs. He does not advocate hysterectomy in all cases of prolapse, or even in all cases of procidentia, but thinks there is a class of cases where nothing short of it will give relief. Each case must be studied individually. There are few conditions requiring greater judgment as to the measures to be taken.

79 Chronic Bright's Disease and Diabetes Mellitus; Diagnosis; Cause and Similarity. B. F. Felch.
80 *Improved Methods and Details in the Care of Patients During Surgical Operations. Fenton B. Turck.

74. Bladder Injuries.—Among the causes of bladder hemorrhages not usually recognized by the physician, Schmidt enumerates ulceration due to breaking down of gonorrheal infiltration of the mucosa, atheromatosis of the blood vessels, cystitis with extravasation, varicose degeneration of the bladder veins, a peculiar condition of the mucosa of the trigonum making it appear fluffy, like a piece of fine fabric and bleeding at the slightest irritation, which has been seen as yet only in women, and direct medical interference such as bi-manual examination or obstetrical operations, and traumatic granulation of the bladder which follows injuries to an already inflamed bladder wall.

78.—This article appeared elsewhere. See THE JOURNAL of July 4, title 74.

80. Protection During Surgical Operations.—Turck describes two or three improvements in the technic of surgical operations. For instance, to avoid peritoneal contamination in abdominal operations he proposes a square sheet of rubber dam with two small openings 3 to 6 in. apart, reinforced by a rubber band forming a collar. This is laid over the wound and the part to be incised, the stomach, for example, in gastro-enterostomy, is drawn through one of the openings, which stretches and hugs closely to the protruding viscus. The loop of intestine selected for the anastomosis is drawn through the other opening. The two parts drawn through the opening are completely isolated from the rest of the peritoneal cavity, as the rubber overlaps the edges of the wound. When the anastomosis is performed the shield is slit open with scissors, the viscera set free, and replaced in the abdominal cavity. Contamination of the peritoneum as the viscera are opened is absolutely prevented. The constricting band around the viscera also prevents hemorrhage and any considerable escape of their contents. The same principle can be used in different operations such as cholecystotomy. As the rubber-covered viscus is grasped and not the viscus directly, there is less danger of injury. Another valuable protective device is what he calls a rubber drainage coffer-dam. Around the drainage tube at the point of insertion—as for example in cholecystotomy where drainage of the gall-bladder is desired—the thin flexible rubber cylinder is stretched around the neck of the gall bladder, and fits snugly to the outer wall, but not enough to shut off circulation. A few stitches hold it in place. A drainage tube is then inserted within the rubber cylinder and stitched into the gall bladder in the usual way. Between the inner drainage tube and the coffer-dam a few strands of suture material are placed for drainage. Gauze can be packed around it in the usual way. Other devices which he uses for preventing shock are small, thin, hot-water bags inserted into the abdominal cavity and the use of heat stimulation of the soles of the feet to prevent shock. To provide heat at a constant temperature during surgical operations he has devised what he calls hot-water-coil slippers, a device which has been of service in the prevention of shock in his own experience. Even when shock is not imminent the use of heat to the soles has a good effect on the circulation and better elimination is established.

Dominion Medical Monthly, Toronto.

August.

81 *The Buried Animal Suture; Its Value in Aseptic Surgery. Henry O. Marcy.
82 *The Operative Treatment of Goiter. George A. Bingham.
83 Successful Operation on Four Cases of Goiter in a Septic Condition. Herbert A. Bruce.
84 His Mother's Legacy. Robert A. Hood.

81. Buried Sutures.—Marcy gives the history of the use of buried animal sutures (preferably tendon) and points out their utility. He thinks the time will come when they will hold the first place in the technic of modern aseptic wound treatment. He advocates the continuous rather than the interrupted sutures, as they do not leave pockets for the accumulation of fluids, and a parallel rather than a glover's stitch, the needle inserted within the tissue parallel to the long axis of the wound, each succeeding stitch made by introducing the needle exactly opposite the emergence of the preceding one. The continuous suture, moreover, requires but a single knot, and is less liable to produce undue constriction since compensation occurs, equalizing the force applied to the entire suture. This he considers of the utmost importance since injury and devitalization follow the earlier method. Fatty tissues should be avoided for buried sutures, but they seldom require independent suturing. He remarks that the interrupted suture is the legacy of the fathers, and was used for the purpose of removal of a stitch as desirable. If our tailor made our clothes in this manner we should wonder at his bungling methods.

82. Goiter.—While a case of benign goiter should only be operated on for relief of definite symptoms, in malignant disease excision of the gland is the only hope. To avoid compression of the important organs Bingham would operate even in advanced malignant disease. He has also operated in exophthalmic goiter and thinks that any case failing to respond to prolonged medical treatment with steady increase of growth should be given the benefit of operative interference. These cases are somewhat more dangerous as regards anesthetics, but he has used chloroform, though the ideal would be local anesthesia. In bad cases of dyspnea he stops the anesthetic as soon as the skin incision is done, and thinks by the intelligent co-operation between surgeon and anesthetist, the patient can be nursed along through the operation without suffering and with a minimum amount of damage, and, being so lightly anesthetized, by his unconscious phonation is able to give an assurance of the safety of the recurrent laryngeal nerve. He makes a shallow U-shaped incision across the tumor from one sterno-mastoid to another, passing through the skin and subcutaneous tissue, platysma and deep cervical fascia. Two flaps dissected up and down, and if necessary the anterior jugular is cut between ligatures. Then the pretracheal layer of the cervical fascia is very carefully incised in the median line. Just below this the capsule of the tumor appears. If it is opened up hemorrhage may be difficult to control. The surgeon should work outside but close to the capsule. The opening in the pretracheal fascia is enlarged as required, the finger introduced, and adhesions between the fascia and capsule broken down. It is then swept around the outer and upper margin of the tumor, forcing the pretracheal fascia and muscles over the edge of the mass, and the superior thyroid vessels are recognized and cut between clamps. This usually releases the outer part of the lobe, which may now be drawn forward and with the finger everything is stripped away from the posterior wall of the capsule. If care is taken to strip closely and from the posterior part of the capsule, the recurrent laryngeal will be pushed away from the inferior thyroid vessels or tied off close to the tumor and the lobe is completely freed, and we see the rings of the trachea to which the isthmus is adherent. No violence must be used in separating the isthmus. The tracheal wall will probably be atrophied by pressure and special care is required. He has often left a portion of the isthmus rather than risk its separation. The junction of the isthmus with the opposite lobe is now transfixed with silk and tied off and the mass cut away. The ligating of the pedicle, while unnecessary so far as hemorrhage is concerned, serves a purpose, he thinks, in preventing the escape of thyroid secretion into the wound. Every possible bleeding point should be tied and care taken to obliterate the huge "dead space," which he does by a series of quilting sutures. Temporary drainage is employed by the Cheyne method, cutting a buttonhole through the lower flap, just above the sternum and drawing a small tube through, the inner end of which lies in the lower part of the wound behind the sternomastoid. A provisional suture is placed in this little wound and tied when the tube is withdrawn after forty-eight hours. If the pretracheal or sternomastoid muscles have been cut, they should be sutured and the wound in the pretracheal fascia closed, running a suture of fine silk close against the wound and applying plenty of dressing. The head is supported between two sandbags. The nurse is instructed to prevent any violent movement of the head when the patient is recovering consciousness, and to compress the dressing gently during vomiting. Tachycardia

and high temperature may be controlled by digitalin and ice bags. In case of adenoma or cystoma of the thyroid, the procedure is modified. The capsule is cut through, the tumor enucleated and hemorrhage is rapidly controlled. There may be partial or complete aphonia after the operation, but it is usually only temporary.

1. **Human and Bovine Tuberculosis.**—Hamilton replies to the critics of his experiments and claims that the tests were adequate and conclusive. He admits that in 4 of the 19 cases of calves inoculated with human tuberculosis a negative or doubtful result was obtained. The criticism made that he did not use the tuberculin test in all his experiments he thinks is useless. If the tuberculin test had been made the charge might then have been that immunity was produced by it. In regard to two cases inoculated with human tuberculosis from one calf to another, with the result of increased virulence, he maintains they were not due to mere accidental over-susceptibility of the animals employed. The opposite side of the question—whether bovine tuberculosis is transmissible to man, of course, can never be proven experimentally.

2. **Obliterative Arteritis.**—In the two cases described by Michels and Weber there was no obvious cause of the endarteritis. The authors seem to think there is a variety of obliterative endarteritis commencing in the arterioles of the extremity, especially in the muscles and subcutaneous tissue, that may possibly be explained by the presence of a nervous element, though the peripheral nerves were found normal. The presence of a nervous etiologic element would form the connecting link with some cases of Raynaud's disease and erythromelalgia.

3. **Miners' Phthisis.**—The subject of miners' phthisis is discussed by Oliver, who arrives at the following conclusions, which, he thinks, cover the points for discussion:

1. That miners' phthisis is not the result of the inhalations of gases given off by the strata, nor evolved by the explosives used in mines. 2. That it is a disease in which there is a marked

excess of fibrous tissue in the lungs, embedded in which can be seen numerous particles of coal dust and siliceous material; in which also cavities may be seen and tubercle occasionally detected. 3. That it is a disease of occupation, due to the irritating action of dust, which renders the individual liable to repeated catarrh; that it is non-tuberculous, not only in the early stages, but may even remain non-tuberculous throughout; that when tubercle is present it is an accidental infection, which, while hastening the end, does not exercise any very marked influence on the pre-existing structural alterations caused by dust, unless it be a tendency towards disintegration. 4. That it is a local disease, purely personal to the individual, and never assuming hereditary characters. 5. That, accepting this view of the pathology of the disease, miners' phthisis, as experience in this country has shown, may be largely prevented by improved ventilation and by the adoption of means for the removal of dust or for the allaying of dust by water.

In the discussion following Adami agreed with Oliver that the disorder was non-tuberculous, as did also Hamilton, who considers it rather an aseptic sloughing due to the altered condition of the lung; that is, in coal miners. In stone masons the lung complication with tubercle at the time of death or sometimes before is frequently met.

4. Splenic Anemia.—By this disease Rolleston understands a condition characterized by splenic enlargement and not correlated by any known cause, with absence of enlargement of the lymph glands, and with anemia of a type midway between secondary anemia and chlorosis. The disease is also characterized by leukopenia or at least no increase of the white blood corpuscles. It has an extremely long course, lasting years with a tendency to periodic hemorrhages, especially of the gastrointestinal tract. He reviews the conditions, the morbid anatomy, especially of the spleen, bone marrow and lymph glands and sums up the important points as follows:

1. Accepting chronic splenic anemia as a clinical entity, is there sufficient evidence to accept it as an established pathologic entity? 2. What significance can be attached to the structural changes in the blood, spleen, bone marrow, etc.? 3. What is the exact relation between splenic anemia and Banti's disease? 4. What is the nature of the disease? Is it an intoxication or an infection? Until the last question is fully answered, any reply to the first must either be suspended or be in the negative.

The subject was discussed by several authorities, among them Senator, who concludes that the reason for the swelling of the spleen is to be found in an abnormal blood condition due to various causes; in some cases, such as those occurring with malaria, rickets, etc., this may be due to a specific blood alteration due to the original infection. In other cases of unknown etiology it must be assumed that injurious substances reach the blood from the intestinal tube through the lymphatics. This is justified by the fact that the abdominal lymph glands are always more or less involved, even where no other swollen glands are found. The spleen is the primary point of attack, and this is supported by the fact that in a number of cases the disease was cured by splenectomy.

11. Adenoids.—Dun has observed cases in the Liverpool Infirmary for Children and finds from his studies that in the great majority of cases the symptoms are slight and do not materially affect the health and development of the child; that medical treatment is sufficient and operative interference uncalled for. On the other hand, there are some cases, comparatively few in number, with definite and severe symptoms, producing marked ill health, usually symptoms of nasal obstruction and catarrh with occasional reflex nervous phenomenon and septic processes. These cases are most satisfactorily treated by removal of the growths.

12. Influence of Brain Power on History.—The title of Lockyer's address is a paraphrase of the well-known work of Capt. Mahan on "The Influence of Sea-power on History." Lockyer compares the educational facilities and the universities of Great Britain to those of Germany and the United States, greatly to the disadvantage of the former, and claims that as the work of Capt. Mahan has aroused the British nation to its needs for naval defense so it should be stirred up to national effort to meet the competition of outsiders in the matter of education. He says to sum up:

I have endeavored to point out to you how the nation at present suffers from the absence of a powerful, continuous, reasoned expression of scientific opinion, urging that we shall be armed as other nations are, with efficient universities and facilities for research to uphold the flag of Britain in the domain of learning and discovery. I have also endeavored to show that, in addition to our many existing councils, another is required to secure that the benefits which a proper co-ordination of scientific effort in the nation's interest can bring shall no longer be neglected. Let me also remind you that in 1859, when the late prince consort occupied this chair, he referred to "impediments" to scientific progress, and said: "They are often such as can only be successfully dealt with by the powerful arm of the state or the long purse of the nation."

13. Abdominal Surgical Diseases.—Bishop calls attention to certain points in regard to abdominal surgery, especially the question of perforation in appendicitis, in gastric and duodenal ulcer, etc. He discusses the symptoms and illustrates by cases the points he makes. He says the abdominal cavity with the structures contained in it may be pathologically looked on the same as a large joint, and the first and automatically present result of inflammatory changes in the peritoneum will be and must be rigidity of the muscles, which ordinarily produce movement between the intestines and abdominal wall. It is more important to emphasize this because it is not persistent, but may disappear early in the case. This particular factor will apply to any case of perforation, duodenal, gastric, enteric or appendiceal and slighter and more localized degrees of it may be seen in localized peritonitis. The fact of having one certain sign to rely on as evidence renders the absence of that sign a tremendous comfort to all concerned. Another point is that of intussusception. Here he calls attention to the misleading remarks on diagnosis of some of the text-books, viz., the classical symptom of sausage-shaped mass in the abdomen, the passage of blood and mucus in the stools, the sudden pain and vomiting and an os-uteri-like body to be felt per rectum. He remarks that if we are to look for any thickened segment of the intestine in these cases that must be at the time it is contracted on itself which is during a paroxysm of pain. It is just at this time that the examination is apt to be neglected. The child is crying violently and is turned over to its mother to be soothed and petted into peace. Then when he is quieted again, when both he and the muscular contractions of his bowel are exhausted, the examination is resumed, and failing to find any trace of it, its existence is ignored. Another symptom often missed, but which must be present in every case, is a bloody exudation of mucus. Intussusception means more than simply the compression of one segment into another; it means strangulation of the mesenteric vessels to some extent. The fluid is prevented from escaping and the capillaries are enlarged. Blood is effused into the lumen of the gut. As for feeling for the end of the intussusception per rectum, it is a most dangerous waste of time. Consider how far it must travel in, say the ileocecal variety, which is the most common, before it can possibly come within the reach of the finger. He also points out the hopelessness of attempting to reduce intussusception by the injection of air or water and is dubious as to the reported cases of success in this way. Maunsell's operation is the only resource. He also notices ectopic gestation and its diagnostic points. The points on which he lays stress are the occurrence of abnormal blood discharges in women with some of the signs of early pregnancy who have had a missed or even slightly delayed period and who complain of pain in either or both thighs extending toward the knee in the course of the obturator or anterior crural nerve. Bi-manual examination in such cases should be done at once. If a small mass is found beside the

uterus, abdominal section should be done at once without delay. Another condition in which somewhat similar symptoms may occur is that of tumor in which the pedicle is twisted, and the tumor becomes engorged. This may occur from a fall or from no apparent cause at all, but there is usually some previous history of an abnormal mass to suggest the condition to be found.

14. **Bovine and Human Tuberculosis.**—MacFadyen has experimented on monkeys with bovine and human tubercle bacilli and found that the animals proved susceptible to the bacillus of bovine tuberculosis either directly or after one passage through the organism of the guinea-pig.

A certain number of the animals died in two or in ten days after feeding with bovine and human tuberculous material. Normal human sputum did not produce this effect and the result suggested some form of intoxication. The monkey fed thrice, twice, or once with the bovine material succumbed to a general tuberculosis in from about one to two months, and, fed with the human material, the same results and fatal effect were produced in about the same period of time. The young monkey proved to be equally susceptible to the bovine and human strains of the tubercle bacilli. The striking difference in the effects produced occurred in the digestive tract. Intestinal lesions were found in the case of every monkey that had been fed with human tuberculous material, while none of the monkeys fed with the bovine material presented any evidence of tuberculous ulcers in the intestine. Within the limits of these experiments it would appear that virulent bovine tubercle bacilli may pass through the intestinal wall in large numbers without any detectable lesion of the gut being produced. It would also appear that a food tuberculosis can be as readily brought about by the bovine as by the human strain of the tubercle bacillus in the young monkey.

20. **The Electric Treatment of Cancer.**—Wright describes the mechanism of cataphoresis and gives the results of his experiments with it in cancer. He finds that the mineral acids thus used would cause a resolution of the skin and tissues, while the metallic salts give rise to necrosis. Alcohol gives rise to the immediate coagulation of albuminous constituents and produces subsequent fibrosis. With liquid paraffin substances can be transferred into the tissues. Iodin, salicylate of soda, lithium, salts and pilocarpin produce their own specific reactions. In his experiments on cancer he employs either a dilute glycerophosphate alcoholature or liquid paraffin in emulsion as a vehicle for the salts employed. The chief of these are cinnamate of strontium, glycerophosphate of lime and strontium. citric acid, iodin, and suprarenal extract. He relies mostly on the first named, but the glycerophosphates have proven useful in assisting in casting off a slough and promoting healing after an application of acid nitrate of bismuth. Citric acid is used for subduing neuralgic pain either alone or in conjunction with phenazonum. Iodin is chiefly used for reducing the indurated glands and promoting absorption, although a strong solution was occasionally used for escharotic effects on the tissues. The suprarenal extract he employed as a preliminary to treatment in most sittings to limit absorption and concentrate the action of the drug. Of the 23 cases of which he has notes he has had good results in 5, which he reports.

21. **Carbolic Acid in Plague.**—Atkinson reports six cases of plague treated by large doses of carbolic acid; 10 gr. being given every two hours for various periods, internally. The blood examination was made for the bacilli during treatment and they were found to have disappeared.

Journal of Tropical Medicine, London.

September 1.

24 *Observations on Akatama, a West Central African Disease. Frederick C. Wellman.
25 Mosquitoes in Relation to Malaria in the Province of Huelva, Spain. Ian MacDonald.

24. **Akatama.**—This is the name given to a sort of peripheral endemic neuritis of obscure origin, characterized by numbness and intense prickling and burning sensations in the presence of cold or damp which are temporarily relieved by the application of dry heat. It is found all over the territory occupied by certain tribes in West Africa in whom 3 to 5 per cent. are more or less disabled by it. The theories of the disease are various. The more probable would be that it might be due to sudden changes of temperature, though the prevalence of the disease is not always coexistent with the exposure. Its being an intoxication analogous to beri-beri is possible, but there are no motor symptoms and it is not especially localized or affected by change of residence. The theory of nerve starvation is not borne out since these tribes are well fed. The diagnosis is easy; the patient himself generally understands what is the matter with him. The prognosis is good as to life and general health, but the treatment is unsatisfactory. Some cases seem to undergo a spontaneous cure.

30 Fracture de la base du crane (of the skull). A. Mignon.

27. **Cysts in Broad Ligament.**—Sikora reviews 3 cases and adds another personally observed in which a large cystic tumor, supposed to be an ovarian cyst, proved to be a parovarian cyst with a twisted pedicle. The pedicle is always wide, 4 to 6 cm., and the torsion is never abrupt, but slow and gradual. The hemorrhage was always too small to induce appreciable symptoms.

Semaine Medicale, Paris.

31 (XXIII, No. 35.) *L'hérédité pathologique et la théorie du plasma germinatif. S. Jankelovitch.

31. **Pathologic Heredity.**—Jankelovitch discusses the later scientific researches which show that in certain families there is an undue tendency to alkalinity of the plasm or to toxicity on the part of the organic fluids or to hypothermia, thus checking the vital action of the phagocytes, or some other similar abnormal condition transmitted from generation to generation which the clinician may in time learn to determine with precision. He accepts this as the scientific foundation for the old theory of the "predisposition" and the mystic conception of the "temperament." Weismann's theory of the germ plasm does not interfere with this conception of pathologic heredity. Admitting that all the ancestral properties are localized in the innumerable biophores or molecules of the germ plasm, we may easily assume a number of combinations between them sufficient to explain all the variations which may occur in the descendants of a single family. We can conceive that the spermatozoa and the ova do not all possess absolutely identical properties, and consequently the product of each fecundation will have only the properties derived from a single spermatozoön and a single ovum. The resulting combination of properties varies for the product of each fecundation.

36 *Anatomische und klinische Beiträge zur Vaporisation des Uterus. H. Fuchs (Kiel).
37 *Differentiation of Fetal Heart Sounds and Umbilical Sounds. O. Hoehne (Ibid.).—Zur Differential-Diagnose von Nabelschnurgeräusch und fötalem Herzgeräusch und zur Indikationsstellung bei intra partum erkannten fötalem Herz-Fehler.
38 *Experiences in Treatment of Suppurative Affections of Adnexa and of Pelvic Connective Tissue. P. Jung (Greifswald).—Erfahrungen bei der Behandlung eitriger Aff. der Adnexe und des Beckenbindegewebes.

32. **Fracture of Pelvis.**—Blumreich's patient fell from a second story when she was 18, alighting on the left side. This side of the pelvis became obliquely contracted, and during childbirth 5 years later did not participate in the birth act. The fetus was perforated, but in a second pregnancy she was delivered of a living child, 42 cm. in length, after application of the metreurynter. Delivery occurred as in case of a generally contracted pelvis.

33. **Treatment of Placenta Previa by Bossi's Method.**—De Paoli reports 19 cases thus treated. The portio was dilated in five to twenty-five minutes without laceration sufficient to

require suture. One of the mothers and 3 of the children succumbed. The purpose of the Bossi method in such cases is solely to prepare the way for immediate extraction of the fetus. De Paoli advocates it instead of cesarean section for placenta previa, and in other cases in which the mother's life is in danger. He thinks asepsis is more certain with it than with metreurynters, etc., and that it is a boon to the general practitioner.

34. **Changes in Ovaries Accompanying Uterine Tumors.**—Runge investigated the adnexa in 7 cases of "syncytial tumors" and in 1 of a vesicular mole, and found the ovaries in cystic degeneration in each instance. The lutein cells also exhibited a marked tendency to proliferation. He did not find these changes in the ovaries accompanying other uterine tumors. He reviews the literature on the subject and adds that the changes described are not the inevitable accompaniment of the moles or tumors. In a recent case an ovarian tumor was found with the structure described, and inquiry revealed a history of expulsion of a mole two years before.

35. **Microscopic Study of the Genitalia After Death in Eclampsia.**—Seitz discovered evidences of inflammation in the decidua, involving part of the fetal membranes and the uterine musculature, in a case of eclampsia in which the patient died during delivery. In a second, similar case nothing of the kind could be detected. The findings are illustrated in colored plates.

36. **Application of Steam to Uterus.**—Fuchs reports 103 cases of hemorrhage treated at the Kiel clinic by curetting and vaporization. In 68 more than four months have elapsed since treatment was concluded, and in 60 of these the treatment has proved a permanent success. The most strikingly favorable results were obtained in cases of preclimacteric hemorrhages. Of course the procedure is applicable only to women past the child-bearing age or as an alternative to extirpation of the uterus. After mild curetting the steam is applied for thirty seconds, at a temperature of 120 C., and the patient is kept in bed for a week to ten days afterward. He gives a cut of the simple apparatus, the steam generator with the thermometer in the top, the small, long tube conveying the steam and the large, protecting "celluvert" tube that is slipped over the steam tube to prevent burning the vagina, etc.

37. **Differentiation of Fetal Heart Defect by the Sounds.**—Hoehne diagnosed, intrapartum, a fetal cardiac defect, confirmed by the anatomic findings. He noticed a rough sound, not synchronous with the maternal pulse, diffused over an area corresponding to the fetal heart while the usual fetal heartbeat was perceptible. This diagnosis was made in 6 out of 7 cases on record. Five of the children died, and the necropsy revealed tricuspid stenosis in 4 and aortic in 1. Two of the children survived, with no special abnormalities.

38. **Experiences with Suppurative Pelvic Affections.**—Jung states that the mortality of 134 cases of suppuration in the pelvis under observation at Greifswald, was 20.5 per cent.; while it was 18 per cent. of the 117 cases operated on. In a third of the fatal cases a communication between the tubal pus pocket and the rectum was discovered, sometimes no larger than a hair in diameter. The pus contained pyogenic cocci in 35.8 per cent. of the total cases; tubercle bacilli in 24.6 per cent., and gonococci in only 14.8 per cent. The mortality in 72 operations without drainage was 23.6 per cent., and 25 per cent. in the 20 cases drained. He has abandoned the practice of rinsing out the cavity, as he found that it washed germs into remote and inaccessible parts.

39. **Operative Treatment of Otitic Thrombosis of the Transverse Sinus.**—It is the rule at Lucae's clinic to open up the sinus at once in every case of high fever occurring in an adult in the course of suppuration of the middle ear when a suppurative meningitis can be excluded. If the sinus is full of blood or the diagnosis is dubious or a thrombus adherent to the wall may be assumed, treatment is expectant at first and the sinus not opened unless the symptoms continue a progressive course. If the thrombus obliterates the sinus, then it must be opened up and the suppurative thrombus removed. It is not necessary to remove with it the soft thrombi until the blood flows. The jugular is not ligated unless there is primary or secondary thrombosis of the medulla with pyemic general infection and the vein itself already affected. In case it is impossible to reach the central end of the decayed thrombus the results of the operation on the sinus are awaited and only in case the pyemic symptoms still persist is the jugular ligated. In every case the ligation of the jugular must be followed by free exposure and evacuation of the focus in the sinus and medulla. He describes a number of cases in detail.

40. **Wandering Liver.**—Savelieff's article is based on 2 cases personally observed and 116 collected in the literature, discussing the etiology, symptoms, diagnosis and treatment. His cases are illustrated.

41. **Filling for Cavities in Bones.**—Fantino and Valan insist that it is necessary to supply the bone salts needed for the regeneration of bone. They accomplish this by filling the cavity with scraps of calcined bones. New bone tissue forms in and through them, utilizing the salts in the bone scraps, and the cavity is completely filled in this way in three to eight months, as shown by radioscopy. In case the cavity is not unconditionally aseptic, they use a mixture of 3 parts pulverized calcined bone, 1 part thymol and 2 parts iodoform. This is pasty at 75 C. and sets at 60 C., forming a mass as hard as bone. In case of osteomyelitis or other suppurative lesion, they first sterilize the cavity by filling it with 10 per cent. iodoform glycerin, which they boil in the cavity by introducing the thermocautery into the fluid. After the sterility of the cavity has been ascertained by test cultures, the cavity is filled with the calcined bone as above. In case the soft parts are sound they can be sutured at once. They have applied this technic in 40 cases and the results were extremely satisfactory in 23 out of 30. The pulverized bone alone is absorbed too rapidly for successful regeneration of bone, but by mixing it in a cement as above described, the aim sought is fully realized as their three years of experience have established.

43. **Sutured Versus Non-Sutured Fractures of the Patella.**—Müller does not attempt to generalize from his material as it is so limited, merely 4 cases of fracture of the patella treated by suture and 11 cases treated by bandaging alone. The healing was complete in 93.1 days in the first and in 98.7 days in the second group, but the after-treatment required 153 days in the first and only 71 in the second, while the mobility of the joint was only 90 degrees at the close of the after-treatment in the first and 120 degrees in the second group. Working capacity was also impaired by 40 per cent. in the first and 24.6 per cent. in the second group.

45. **Cancer in Animals.**—Loeb mentions that he has frequently discovered carcinomata in the eyes of animals, and adds that they are comparatively frequent in cattle at the Chicago Stock Yards. At least one a week is found, and sometimes 2 or 3. During 1899 only 2 external carcinomata were noted elsewhere than the eyes, in the 50,000 cattle slaughtered. On a certain farm in Wyoming carcinoma in

the eyes of the cattle seems to be endemic. No cases occur in the neighborhood. He states that of the 61 cattle he has observed with carcinoma in the eyes, all but 2 were cows. In 1 there was a carcinoma in each eye, and in another one eye and the vulva were affected.

46. **Anastomosis After Resection of the Epididymis.**—Rasumowsky's method of implantation of the sound vas deferens after resection of the epididymis was tested on animals by Bogolyuboff. He found that the continuity of the efferent seminal passages became re-established in time. An intermediate space forms in which the vas deferens debouches from one side and the vasa of the epididymis from the other. The operation has been performed eleven times at Kazan, all on account of tuberculosis, and all on 7 patients. In 4 the epididymis was totally and in 7 partially resected. The clinical and experimental results are extremely encouraging.

54. **Consequences of Ligating Femoral Vein.**—Halberstäder relates a case from his own experience at Königsberg to show that this procedure is by no means always free from danger. His patient was a man of 52; a piece of the femoral vein 5 cm. long was resected below Poupart's ligament in removing a tumor. Notwithstanding every known precaution, gangrene followed, but still he thinks that a favorable result is possible when collateral routes exist in sufficient numbers and the femoral artery is intact.

56. **Extensive Resections of Small Intestine.**—Nagano cites 12 cases in which more than 200 cm. of the ileum was resected. Six of the patients are entirely restored to health.

60. **Foreign Bodies in Esophagus.**—The statistics of 215 operations for this cause are tabulated with various details. Artificial teeth form 40.7 per cent. of the total, and pieces of bone 7 per cent. The mortality from the latter is the largest, being 15.38 per cent.

85 Location of Foreign Bodies with X-Rays. Levy-Dorn and M. Jacobsohn (Berlin).—Zur Untersuchung auf Fremdkörper mit Roentgen-Strahlen.

64. **Method of Differentiating Organic Sensory and Motor Disturbances in Fingers.**—The method is based on the illusion experienced by contact of the crossed fingers, the sensation of contact being attributed to the wrong finger or part of the finger. This illusion occurs constantly in persons with psychogenic anesthesia of the parts, while in subjects with true organic anesthesia there is none of this illusion. Müller has devised a means of applying this test in the clinic and illustrates its various applications. The hands are clasped together, with the interlacing fingers turned outward, in front of the neck. The subject is thus unable to see his fingers and the illusion is very pronounced.

66. **Embryomata and Other Tumors.**—Beard's idea is that all tumors are of embryonal origin, due to displacement of primary germinal tissue cells. Any part whatever of the life cycle of normal development may manifest itself as a tumor. Carcinoma is the sole exception, and this, he states, bears the stamp of the pre-embryonic life cycle.

67. **Relations Between Chorea, Rheumatism, Etc.**—Hohlfeld suggests that the four affections enumerated in his title may possibly have a single origin, and that their frequent combination is not a mere coincidence. He calls special attention to the occurrence of various members of the group in different members of the same family.

69. **Inoculation of Man with Bovine Tuberculosis.**—Lassar describes several cases from his own experience in which butchers or persons who had much to do with diseased cattle acquired superficial lesions which seemed to be undoubted cases of inoculation of bovine tuberculosis. He gives cuts of some of the subjects and microscopic findings.

71. **Firearm Wounds of Lungs.**—König advocates expectant treatment of a bullet wound of the lung even with considerable extravasation. Thoracotomy may be necessary if after two or three days the hemothorax still induces fever and dyspnea. It is likewise indicated at this date or later if the hemothorax persists, even in the absence of urgent symptoms. If absorption proceeds very slowly, puncture may be advisable.

72. **Transverse Spinal Paralysis from Neoplasm.**—Nonne's case was distinguished by the fact that the paralysis was not due to compression by the malignant neoplasm but merely to simple degeneration of the cord under the influence of the toxins generated by the primary tumor in the prostate and the metastases affecting all the vertebræ.

73. **Neutrophile Granulations of Blood.**—Mosse believes that he has established that the myelocytes are the essential neutrophile elements, and that we must accept a basophilia of greater and lesser degree.

74. **Thyroid Treatment of Cretinismus.**—M. Levy found that thyroid treatment proved very beneficial in 7 cases of endemic cretinism, the same as in the sporadic form. In this his experience differs from that of Schulz at Graz, who was unable to detect any improvement in 100 cases of the endemic variety treated with thyroid extract. Possibly the endemic cretinism in Alsace, where Levy's tests were made, is not so deep-rooted as at Graz.

76. **Self-Protection in Roentgen Work.**—Beck suggests that the tubes should be tested on the bones of a hand or arm fastened on pasteboard, instead of testing them on the operator's own hand or arm as is too often done.

77. **Osmic Acid in Clinical Microscopy.**—Posner states that he has found the fumes of osmic acid very useful for fixation of fresh specimens of blood or other organic fluids. It "suffocates" the cell and preserves it in its natural outline better than any other substance. He keeps a few crystals of osmic acid in a jar with a close cover. The object glass to be examined is laid over the top of the jar with the cover above it, and the fixation is complete in 40 seconds.

78. **Narcosis in Ileus.**—Kausch prefers general narcosis for operating in ileus except when the operation is so trifling that local anesthesia will prove sufficient. In order to obviate the danger of aspiration of vomited matters during the narcosis he plugs the opening of the stomach into the esophagus. This is done by means of a rubber bag on the end of a fine tube tied to the sound. The bag is introduced into the stomach with the sound, which projects a little below the bag. The latter is then inflated through the narrow tube, thus completely closing the entrance into the esophagus. The contents of the stomach and intestines can find their way out through the sound if necessary, as he operates with the pelvis raised.

79. **Henoch's Purpura.**—Rommel describes a typical case observed in a boy 3 years old. Bacteriologic examinations were negative and nothing abnormal could be discovered in the heart. No treatment displayed any efficacy except possibly the opiates. The affection showed a pronounced tendency to recurrence.

81. **Epidural Injections in Treatment of Incontinence, Etc.**—THE JOURNAL described Cathelin's method of epidural injections, vol. xxxvii, pages 150 and 793, and vol. xxviii, page 1282, and has recently chronicled a number of successes with it in the treatment of urinary incontinence, etc., page 527, ¶117, and page 757, ¶124. The needle is inserted at a point just above a line drawn across the bases of the bony pro-

Figure 1.

tuberances that form the triangle visible or palpable at the lower segment of the sacrum, x in Fig. 1. The needle is inserted as shown at A in Fig. 2 until it nearly touches the bone, then the handle is depressed until the needle parallels the bone, when it can be freely inserted quite a distance without coming in contact with bone or other tissues. The best position is the erect, but it may be necessary to have the subject recline on the left side and flex the limbs to bring the bony triangle into prominence. It is never exactly in the

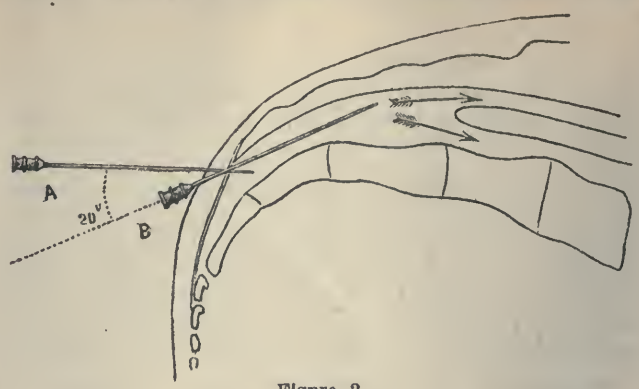

Figure 2.

anal furrow but a little above it as the subject reclines on the left side. For further particulars see references above.

82. **The Omentum as a Protecting Organ.**—The researches on dogs reported establish that the omentum has more functions than hitherto appreciated. If, for example, the circulation of the spleen is entirely cut off, the omentum gradually envelopes and forms a capsule around the spleen inside which it is in time completely absorbed. If the omentum is removed after the circulation in the spleen is cut off, the organ does not become encapsulated and the animal speedily dies. When toxins are generated by gangrenous degeneration of the spleen or other organ the omentum seems to possess the power of neutralizing these toxins. Foreign bodies introduced into the abdominal cavity were likewise encapsulated by the omentum.

83. **Studies of Action of Collargol.**—Bamberger describes experimental researches and tests on his own person which show that the silver salts do not remain dissolved in the serum, and that they have no particular bactericidal action. Their unquestionable beneficial action is due, he thinks, to the mobilization of the leucocytes which they induce.

100 Report of Committee on Foot-and-mouth Disease, 1901-2. Loeffler (Greifswald).

92. **The Housing Problem.**—Hueppe discusses the recent regulations on this subject in Prussia, and recommends among other things that a building line should be established in residence districts a certain distance back from the street, back of which nothing in the way of buildings should be allowed,

with fences not over six feet in height between the different yards. This would give an open square in the center of the block, even if the street front were built up solid, and he remarks that the air in such a square is surprisingly good, sheltered from the dust of the surrounding streets. He states that up to the end of the seventeenth century the arrangement and building of German cities were considered matters of public concern and accommodations were provided ample for all, with rents low. In the unprecedented flocking of the people from the country to the city in the last century the provisions for housing the multitudes proved inadequate. He insists that small houses are cheaper to build and maintain and more remunerative for a district in the end than many-storied tenement houses, especially if, as the new Prussian law contemplates, the special assessments, water tax, etc., are reduced 25 per cent., when it is shown that the houses are occupied by the poorer classes.

94. **Chronic Gonorrhea and Its Treatment.**—Meyer has followed 90 cases of chronic catarrhal urethritis for months or years, controlling the microscopic findings with cultures and clinical observation. He advocates making cultures from the secretions as a routine procedure of the greatest importance for treatment and indispensable to a proper understanding of the case. By repeated inoculation of the secretions on suitable culture media he succeeded in demonstrating gonococci in 50 per cent. of the total 90 cases. In 58 cases the microscope and the cultures gave identical results, while in 29 cultures developed when the microscope findings were negative. The microscope sometimes revealed the cocci after a preceding irritation of the mucosa, but the cultures revealed them without the necessity for this irritation. The culture medium found best adapted for the purpose was Kiefer's mixture of 3.5 per cent. agar, 5 per cent. peptone, 2 per cent. glycerin, and .5 per cent. salt, adding one-third by volume of sterile ascitic fluid.

95. **Successful Immunization of Cattle Against Tuberculosis.**—Neufeld presents the official report of the researches which Robert Koch has been conducting during the last two years, and which have established the possibility and feasibility of rendering cattle absolutely immune to tuberculosis. They also confirm his assertions in regard to the non-identity of human and bovine tuberculosis. His conviction that the agglutinating power and the degree of immunity are intimately connected has also been confirmed as the method of treatment which induced the highest agglutinating power ensured the highest degree of immunization. The non-identity of human and bovine tuberculosis was the key that solved the problem of immunization, as he found it possible by preliminary treatment with one kind of virus to immunize the animal against the other kind. Neufeld mentions that this possibility has been suggested by Macfadyan, von Behring, Pearson, Leonard and Gilliland, but Koch's researches had been long under way before their publications and his technic is different. He delayed publishing his report for the reason among others that he was hoping to be able to immunize other animals, such as the guinea-pig, which is very susceptible to both bovine and human tuberculosis. This wish has not been realized to date. The general plan of the immunization was to commence with injections of dead tubercle bacilli and then continue with increasing doses of living cultures, first of human tuberculosis and then of bovine tuberculosis—*Perlsucht*, reaching as large doses of each as possible. This general plan was varied in a number of ways, as, for instance, some of the animals were treated with the living bacilli from the first, and it was possible to confer immunity by this means likewise. In all the animals, however, asses, goats and cattle, it was soon found that a limit was speedily reached beyond which it was impossible to go. This limit is not established by the action of the infection, but by the action of the toxins of the cultures. In this respect human and bovine tuberculosis proved to be about on a level, or rather the toxic action of *Perlsucht* is unmistakably stronger than that of the human cultures. It was impossible to determine the minimal fatal dose, as the susceptibility to the toxin varied in different animals, and even in the same animal at different times. In asses it ranged from 50 to 100 mg. of human tubercle bacilli, while goats tolerated only 30 mg. of human and 20 mg. of bovine tubercle bacilli, and even 10 mg. sometimes proved fatal. This toxic action of the cultures established a limit to the process of immunization beyond which it was impossible to bring the animals, even after being long accustomed to the injections. This is similar to what is observed in typhoid and cholera, but the conditions are much more complicated in tuberculosis. In the former the toxic phenomena can be induced with killed bacteria if large enough doses are given, but this is not the case with tuberculosis. Even the intravenous injection of up to 300 mg. of the killed cultures caused slight reaction in goats. This is the more remarkable, as killed tubercle bacilli have the same power as living cultures to induce local toxic action; that is, the formation of nodules. Another remarkable feature of the toxic action in tuberculosis is the fact that it occurred exclusively in those animals that had previously been treated with tuberculosis cultures. The acute intoxication never developed in animals that had not had the preliminary treatment, even after much larger doses, as much as 100 mg. in goats. On the other hand, a peculiar chronic intoxication developed after very large doses. The acute intoxication proved fatal in less than twenty-four hours, and the findings correspond to those observed in tuberculin intoxication of tuberculous animals. He protests against the assumption from these facts that in both cases the toxin is the same, for otherwise it would have proved possible to protect the animals against the intoxication described by interposing treatment with progressive doses of tuberculin. This, however, was never accomplished, and the hope that tuberculin administered after a large dose of living cultures might avert the impending intoxication was never realized. This acute intoxication occurred approximately the same in asses, goats and cattle and proved an obstacle to the animals becoming accustomed to the injections. Another circumstance which rendered the immunization difficult was observed in the goats alone, namely, the injurious effect of too large or too frequently repeated doses of human tubercle bacilli. When too large doses were injected (30 to 60 mg. in fractional doses) little if any immunity was acquired, while with smaller doses the animals were rapidly rendered immune. The injections were always intravenous and the cultures were two to four weeks old, grown on glycerin bouillon or the Beck-Proskauer culture medium, dried with blotting paper, weighed and ground in a mortar with physiologic salt solution. The fluid was thoroughly shaken up and about 5 to 10 c.c. injected at a time. If the bacilli enter the circulation in lumps they are liable to induce the formation of a cavity in the lungs, even in an immunized animal. When the immunization had resulted positively and sufficient time had elapsed, small, smooth-walled, perfectly healed cavities were found in the lungs, entirely free from tubercle bacilli. If the animal dies or is killed a few weeks after the last immunizing injection, then, as is to be anticipated, more or less numerous indurated grey nodules undergoing retrogression will be found in the lungs. The desiccated bacilli were ground and injected in suspension in saline or centrifugalized or in glycerin after sedimentation. The cultures of *Perlsucht* bacilli were always extremely virulent. Goat No. 26, for example, was injected with .025 gm. ground (killed) tubercle bacilli, with eight days later an injection of .0025 gm. human tubercle bacilli, and eleven days after this an injection of .01 gm. *Perlsucht* bacilli. The animal died with symptoms of acute intoxication immediately after injection of .02 gm. *Perlsucht* bacilli seven weeks later, and in the lungs were found a number of minute, hard and evidently retrogressing nodules. As a typical example of the immunity conferred we quote the record of ass No. 8: April 8, 1902, 1 gm. ground (killed) tubercle bacilli in saline solution; April 26, .02 gm. culture human tubercle bacilli; May 10, .05 gm. ibid; June 18, .01 gm. *Perlsucht* culture, and September 18, .02 gm. ibid. The animal is living and apparently healthy, and has been repeatedly tested with doses of virulent bovine tuberculosis cultures, rapidly fatal for the controls. None of the immunized animals

has shown signs of infection during the year and more that have elapsed since the immunization, and those that have been slaughtered have shown no signs of progressing tuberculosis. In conclusion, Neufeld points out that the results of this research do not conflict with the excellent effects of Koch's method of "immunizing treatment" of tuberculous human beings with preparations of killed, ground tubercle bacilli which are readily assimilated by the organism. In the first place, the immunization of animals is obtained by means of a brief preliminary treatment which enables them to withstand the following doses of otherwise fatal cultures, while in man it is a question of gradually arresting a chronic process by treatment continued through months and years. We know also that the reactions induced in tuberculous subjects by injection of tuberculosis toxins are entirely different from those induced in the healthy.

96. **Traumatic Tardy Apoplexy.**—Kron analyzes the cases that have been published, and remarks that only 4 out of the total 10 are above the suspicion of a predisposition. In expert testimony in damage suits the physician should refer to the uncertainty at present prevailing in regard to the subject. He notes one case in which symptoms occurring not long after a trauma indicated tardy hemorrhage with perforation into the ventricle in a previously robust man. The necropsy revealed, however, a tumor in a parietal lobe.

97. **Migrating Phlebitis.**—Neisser gives a careful study of a case which justifies the descriptive title of syphilitic migrating phlebitis of the superficial veins of the limbs.

98. **Relation of Cyclic Albuminuria to the Circulation.**—Edel presents arguments in favor of the assumption that cyclic albuminuria is due to a certain insufficiency of the circulatory apparatus. He noticed that the increase in the blood pressure which normally occurs after moderate exercise was followed by abnormally low pressure in those subjects inclined to cyclic albuminuria. The subjective sensation of fatigue paralleled the recurring albuminuria. In one of the numerous tests he describes he had 2 of these patients lie down and artificially induce disturbances in the respiration by straining as at stool for ten to fifteen minutes. This was invariably followed by albuminuria, although the urine had been free from albumin before, and nothing of the kind was observed in the normal controls. The conclusions of his research are that cyclic albuminuria should be treated by measures to tone up and strengthen the heart muscle and its nerves—not by rest, as hitherto advocated. He even goes so far as to proclaim that the prospects of treating chronic nephritis in the same way by appropriate "gymnastic therapy" are more and more encouraging. He has been successful in curing many cases of cyclic albuminuria along these lines and has achieved equally good results in chronic nephritis. He emphasizes the point that the albuminuria does not recur during the increased blood pressure and respiration that accompany physical exercise, but only in the phase of depressed pressure which follows. The efficacy of diuretics in such cases is due to the improved circulation through the kidneys which they produce. He cites Schaps to the effect that among 35 patients with cyclic albuminuria observed at Breslau, 20 had more or less pronounced heart affections. He compares the condition in cyclic albuminuria to that of a convalescent from an infectious disease, only that it is permanent. The subject is a chronic convalescent.

102. **Staining the Gonococcus.**—Pappenheim gives a historical sketch of the various stains proposed for the gonococcus, pointing out their advantages and drawbacks. His own stain is a concentrated 5 per cent. carbolated water solution of 2 parts methyl green and 1 to 3 parts pyronin. The stain is left in contact for three to five minutes. The nuclei are a bluish green to lilac and the cocci dark red. This brings out the gonococci even when they are very scantily present. When more details are desired his universal stain is a combination of this with the Neisser and Steinscheider technics: 1, carbol-gentian; 2, Lugol's solution for three minutes; 3, Nicolle's alcohol plus 1/5 acetone, not less than half a minute and not more than two or three minutes; 4, orange G; 5, blotting paper; 6, the carbol-methyl green and pyronin solution; 7, rinsing; 8, drying and mounting. This shows up the cell nuclei green, the oxyphile plasm of the neutrophile leucocytes yellow as also the eosinophile granulations; the mast-cell granules purple or scarlet; the bodies of the epithelial cells pink and of the lymphocytes purplish red, while the gonococci are red and the iodin-proof bacteria are dark blue.

106. **Inherited Immunity to Syphilis.**—Tschlenow discusses the various contradictory communications that have been published in regard to Profeta's law. He describes 2 cases personally observed in which the children of syphilitic mothers had unquestionably acquired syphilis after birth. In one case the mother was in the tertiary stage, and in the other had had syphilis and been well treated several years before. In the first case the child became infected five years after its birth, and in the latter case between the second and third month. He admits the existence of inherited immunity, but regards it as likely to be transient, and believes that it does not last long after birth, and that such children are as liable then to acquire syphilis as others.

107. **Treatment of Psoriasis.**—Dreuw has derived great benefit from the salve he describes, especially in case of isolated, much indurated foci of psoriasis and in the persisting relics of old psoriasis. He has thus treated a large number of patients at Unna's clinic and also in the latter's private practice. The formula is 10 parts salicylic acid to dissolve the horny substance, 20 parts of chrysarobin and also of Ol. rusci nov., and 25 parts each of green soap and vaselin. This salve is applied with a brush to the foci for three or four days.

109. **Abortive Treatment of Gonorrhea.**—Engelbreth's method is applicable only to purely epithelial gonorrhea. This can be differentiated by the absence of inflammation at the orificium during the first to the third day of the gonorrhea. His method aims to remove the epithelium as in curetting the uterus. He accomplishes this by systematic destruction of the layers of the epithelium by means of strong solutions of silver nitrate (.2 to .3 per cent.), with which he irrigates the anterior portion of the urethra and which cures the gonorrhea in two days

in nine out of every ten cases. In his experience the cases with a longer period of incubation ran a milder course than the others, either from lesser virulence on the part of the germs or greater resisting power of the tissues.

114. Improved Syringe for Treatment of Gonorrhea.—The same writer describes and illustrates a syringe which consists of a rubber bulb, a connecting tube with valve, and the glass syringe proper. He claims that it acts with such delicacy and precision that there is no fear of its getting out of order, but its principal advantage is that the amount injected always corresponds to the varying capacity of the anterior portion without forcing the sphincter. It thus allows thorough and exclusive treatment of the anterior portion. He reviews the history of syringe treatment from the days of ancient Egypt, and enumerates the conditions for success. The capacity of the syringe must be at least 21.5 c.c., as the capacity of the anterior portion ranges from 4 to 21.5 c.c. For injections into the posterior portion the capacity should be 25 c.c. The pressure of the injection should not be above 1/10 of an atmosphere, as the elastic pressure of the sphincter is only 1/9 to 1/7. The injections should be made slowly, bearing in mind this elastic action of the sphincter. They should be brief and often repeated, as the sphincter becomes fatigued easily. Protracted injections for this reason should be made under low pressure, and the urethra only half filled. In injecting the posterior portion the bladder should be emptied and the patient should urinate during the injection, as this reduces the pressure to its lowest point, 1/20 atm.

116. One Cause of Iodoform Eruptions.—Audry states that he has ceased to have any iodoform eruptions in his practice since he has refrained from using iodoform on a patient who is taking mercury in any form. He thinks the eruption is in fact a "hydrargyride" induced by the iodoform.

124. New Method of Treating Lupus.—Dreuw has been applying for four months at Unna's clinic a combined method of treating lupus, which has had unexpectedly fine and rapid results in the 9 cases in which it has been used. Some of the patients had been under treatment for twenty to twenty-two years, and all were delighted at the cosmetic results obtained by the new method. Time alone will reveal whether the cure is permanent, but the prospect is encouraging, as even with the diascope no nodules can be detected. Tuberculous ulcers and granulations healed under this treatment remarkably well and promptly. One of his patients had tuberculous ulcerations on nose, cheeks and at the corners of the mouth. All the lesions have healed over during the five weeks of treatment and the interference with eating vanished after the first sitting. One patient had suffered for twenty years with an exfoliating lupus covering face and lids. The entire surface has healed over with a smooth and shiny surface. He adds that no time nor expense is required for this method of treatment which is within the reach of every practitioner and patient. The procedures are not painful and no symptoms of intoxication have been observed in any instance. The method is a combination of refrigeration with ethyl chlorid and the application of crude hydrochloric acid to the nodules, rubbing it in until it smarts. A region about the size of a dollar is sprayed with the chlorid until covered thick with ice. A cotton-wound stick is then dipped in the acid and it is rubbed into the lupous patch as hard as the patient can bear except in case of exfoliating lupus or tuberculous lesions, in which the pressure need not be so energetic. The acid is rubbed in until the epidermis at the spot forms a grayish soft mass. This is cast off in the course of a few days without leaving any deep lesion. The cauterization is never deep. After this destruction of lupous tissue the epidermis is regenerated from below. In one of his cases a recurring lupous patch on the cheek was cauterized away in a single sitting. Four weeks later the entire granulating surface was covered with apparently healthy epidermis. If the acid becomes diluted with the melting ice it loses its efficacy and a fresh cotton-tipped stick should be taken. The acid is not painful when applied only to the frozen surface, and any tendency to painfulness is combated by renewed application of the ethyl chlorid. It is possible to go over large surfaces in this way at a single sitting. The cauterizing action of the acid does not extend beyond the spot treated. He found it an advantage in some cases, when the nodules had disappeared to the eye, but could still be seen by the diascope, to paint them with ink. This showed through the layer of ice and he could thus apply the acid exactly where needed. Bleeding is soon arrested by the cauterization. He believes it might be advisable in case of very extensive lupus to administer chloroform and go over the entire surface at a single sitting.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

Text-Book of Histology. Including the Microscopic Technic. By Dr. Philipp Stöhr, Professor of Anatomy at the University of Würzburg. Fifth American from the Tenth German Edition. Translated by Dr. Emma L. Bilstein, Formerly Director of the Laboratories of Histology and Embryology, Woman's Medical College of Pennsylvania. Edited, with Additions, by Dr. Alfred Schaper, Professor of Anatomy, University of Breslau. With 353 Illustrations. Cloth. Pp. 485. Price, $3.00 net. Philadelphia: P. Blakiston's Son & Co. 1903.

A Handbook of Obstetric Nursing. For Nurses, Students and Mothers. Comprising the Course of Instruction in Obstetric Nursing Given to the Pupils of the Training School for Nurses Connected with the Woman's Hospital of Philadelphia. By Anna M. Fullerton, M.D., Formerly Obstetrician, Gynecologist and Surgeon to the Woman's Hospital of Philadelphia. Sixth Revised Edition. Illustrated. Cloth. Pp. 270. Price, $1.00 net. Philadelphia: P. Blakiston's Son & Co. 1903.

Scheme for the Differential Testing of Nerves and Muscles. For Use in Diagnosis. By J. Montgomery Mosher, A.M., M.D., Clinical Professor of Insanity, Neurology and Electro-therapeutics, Albany Medical College. Illustrated. Cloth. Pp. 58. Price, $1.00 net. Albany, N. Y.: Brandow Printing Company. 1903.

Yearbook of the United States Department of Agriculture. 1902. Cloth. Pp. 912. Washington: Government Printing Office. 1903.

The Public Service.

Army Changes.

Movements of Officers of the Medical Department, U. S. Army, under orders from the Adjutant-General's Office, Washington, D. C., for the week ending Saturday, Sept. 12, 1903:

Brown, Orville G., first lieut. and asst.-surgeon, will proceed to Washington Barracks and report, not later than September 12, for temporary duty thereat during the absence of Major Henry P. Birmingham, surgeon, and, on the return of Major Birmingham, surgeon, will rejoin his proper station.

Foster, Charles L., first lieut. and asst.-surgeon, will proceed to Fort Washington for temporary duty during the absence of First Lieut. Charles R. Reynolds, asst.-surgeon, and, on the return to duty of the latter officer, will rejoin his proper station.

Geer, Charles C., first lieut. and asst.-surgeon, is granted an extension of leave for one month on account of sickness.

Jones, John F., contract surgeon, is granted an extension of leave for one month.

Koyle, Fred T., contract surgeon, is relieved from further duty in the Division of the Philippines, and will, on the expiration of his present leave, proceed to Fort Clark for duty.

Page, Henry, captain and asst.-surgeon, is relieved from duty at Fort Mason and will report to the commanding general, Department of California, for transportation to the Philippine Islands on the transport to sail from San Francisco on October 1, and will report to the commanding general, Division of the Philippines, for assignment to duty.

Peed, George P., first lieut. and asst.-surgeon, is relieved from further duty at the U. S. General Hospital, Washington Barracks, and will proceed to Fort Bayard for duty.

Reynolds, Frederick P., captain and asst.-surgeon, is granted leave of absence for ten days from about September 10.

Reynolds, Charles R., first lieut. and asst.-surgeon, will, on the arrival of First Lieut. Charles L. Foster, asst.-surgeon, proceed to Washington Barracks and report at the General Hospital for duty with Company of Instruction No. 1, Hospital Corps, during the Army maneuvers to be held at West Point, Ky., and Fort Riley, Kas., and, on the return of the Company of Instruction to Washington Barracks, will rejoin his proper station.

Truby, Albert E., captain and asst.-surgeon, is relieved from further duty at West Point, N. Y., and will proceed to Alcatraz Island, Cal., for duty.

Tetamore, Frank L. R., contract surgeon, having completed the duty for which he was ordered to Fort Grant, will, on the expiration of his present leave, proceed to San Francisco and report for duty with the Seventh Infantry, en route to the Philippine Islands and, on arrival at Manila, will report for assignment to duty.

Williamson, Llewellyn P., first lieut. and asst.-surgeon, is relieved from further duty at the U. S. General Hospital, Presidio, Cal., and will proceed to Jefferson Barracks for duty.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending Sept. 19, 1903:

Asst.-Surgeon J. P. Trainor, from the *Solace* to the Naval Station, Pollock, P. I.

Medical Director Paul Fitzsimmons, from Naval Hospital, Newport, R. I., home, and wait orders.

Medical Inspector H. Wells, from Navy Yard, Boston, to Naval Hospital, Newport, R. I.

Medical Inspector E. Z. Derr, to Navy Yard, Boston.

Medical Inspector D. N. Bertolette, from Naval Medical Examining Board to Naval Dispensary, Washington, D. C.

Surgeon G. T. Smith, to Naval Hospital, Norfolk, Va.

Surgeon M. F. Gates, from the *Atlanta*, two weeks' leave, to Philadelphia Hospital.

Surgeon W. M. Wheeler, from the *Alabama* to Naval Hospital, Newport, R. I.

Asst.-Surgeon J. A. Randall, commissioned June 26.

A. A. Surgeon A. H. Wise, to Naval Hospital, Philadelphia.

Surgeon J. M. Edgar, to the *Rainbow*.

Asst.-Surgeon J. L. Nelson, from the *Iris* to Naval Station, Cavite, P. I.

Asst.-Surgeon A. E. Peck, from Naval Station, Cavite, to the *Iris*.

Surgeon G. A. Lung, to the *Columbia*.

Surgeon C. H. T. Lowndes, to the Naval Hospital, Boston.

A. A. Surgeon P. L. Cocke, resignation accepted, to take effect September 21.

The following assistant surgeons were ordered to report September 30 at the Naval Medical School, Washington, D. C., for special course of instruction: W. S. Hoen, J. P. DeBruler, J. A. Randall, from the Naval Hospital, Norfolk, Va.; A. D. McLain, from the U. S. R. S. *Wabash;* C. C. Grieve, from the Navy Yard, Boston; A. J. Gieger, from Naval Medical Examining Board, Washington, D. C.; R. L. Sutton, from special duty, Baltimore; J. S. Woodward, P. T. Dessez, from Naval Hospital, Washington, D. C.; J. R. Dykes, from the U. S. R. S. *Franklin;* P. S. Rossiter, T. N. Pease, B. H. Dorsey, from Naval Hospital, Newport, R. I.; R. E. Riggs, from Navy Yard, Washington, D. C.; W. B. Smith, from Naval Hospital, Pensacola, Fla.; F. W. S. Dean, C. F. Ely, F. G. Abeken, from New York Hospital; W. W. Verner, H. L. Brown and W. H. Rennie, from Philadelphia Hospital; C. E. Ryder, J. D. Manchester, S. L. Scott, from Naval Hospital, Chelsea, Mass.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Sept. 17, 1903:

Assistant Surgeon-General A. H. Glennan, to proceed to Wilmington, Del., for special temporary duty, on completion of which to rejoin station.

Assistant Surgeon-General G. T. Vaughan, granted leave of absence for fifteen days from Sept. 18, 1903.

Surgeon C. T. Peckham, granted leave of absence for one and one-half months from Sept. 16, 1903.

P. A. Surgeon Joseph B. Greene, granted leave of absence for one day, Sept. 16, 1903.

P. A. Surgeon R. H. von Ezdorf, to proceed to New Orleans, and wire arrival; to proceed to Laredo, Texas, for special duty, September 16.

Asst.-Surgeon T. F. Richardson, relieved from duty at Tampico, Mexico, and directed to rejoin his station at New Orleans, and inspect en route Linares, Monterey and Victoria, Mexico, and Laredo and Eagle Pass, Texas, September 14. Order of September 14 amended so that he will return direct to Laredo, Texas, and inspect service en route to New Orleans.

A. A. Surgeon L. C. Bean, granted leave of absence for four days from September 15.

A. A. Surgeon B. W. Goldsborough, granted three weeks' leave of absence from September 10.

A. A. Surgeon W. H. Marsh, granted leave of absence for three days from Sept. 18, 1903.

A. A. Surgeon F. R. Smyth, granted two weeks' leave of absence from Sept. 10, 1903.

A. A. Surgeon W. S. Walkley, granted leave of absence, September 14 to 18, inclusive.

A. A. Surgeon D. M. Echemendia, granted leave of absence for seven days from Aug. 27, 1903, on account of sickness.

Pharmacist F. S. Goodman, first class, granted leave of absence for five days from Sept. 5, 1903, under provisions of paragraph 210.

Pharmacist S. W. Richardson, first class, relieved from duty at Portland, Me., and directed to report at Bureau for temporary duty.

Pharmacist Charles R. McBride, third class, relieved from duty at Stapleton, N. Y., and directed to proceed to Manila, P. I., and report to P. A. Surgeon V. G. Heiser, chief quarantine officer, for assignment to duty.

Pharmacist C. H. Bierman, third class, directed to report at Bureau for duty.

Pharmacist George I. Van Ness, directed to proceed from McLean, Ill., to Stapleton, N. Y., and report to medical officer in command for duty and assignment to quarters.

BOARDS CONVENED.

Board convened at San Francisco Sept. 25, 1903, for purpose of making physical examination of applicant for position in Revenue Cutter Service. Detail for board: P. A. Surgeon W. G. Stimpson, chairman; Asst.-Surgeon Carl Bemus, recorder.

Board convened at Boston Sept. 15, 1903, for the physical examination of First Lieut. George M. Daniels, Revenue Cutter Service. Detail for the board: Surgeon R. M. Woodward, chairman; Asst.-Surgeon W. C. Rucker, recorder.

APPOINTMENTS.

Clarence H. Bierman, pharmacist, third class.

George I. Van Ness, Jr., pharmacist, third class.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Sept. 19, 1903:

SMALLPOX—UNITED STATES.

California: Los Angeles, Aug. 29-Sept. 5, 3 cases; San Francisco, Aug. 30-Sept. 6, 3 cases.

Illinois: Belleville, Aug. 23-Sept. 12, 13 cases; Chicago, Sept. 5-12, 4 cases.

Indiana: South Bend, Sept. 5-12, 1 case.

Louisiana: New Orleans, Sept. 5-12, 1 case, 5 days in city.

Massachusetts: Fall River, Sept. 5-12, 3 cases.

Michigan: Marquette, Aug. 29-Sept. 5, 1 case; Port Huron, Aug. 31-Sept. 16, 2 cases.

Minnesota: Stearns County, Aug. 31-Sept. 7, 3 cases.

Missouri: St. Louis, Sept. 5-12, 2 cases.

New York: Niagara Falls, Sept. 5-12, 1 case.

Pennsylvania: McKeesport, Aug. 31-Sept. 5, 1 case.

Utah: Ogden, Aug. 1-31, 11 cases; Salt Lake City, Aug. 29-Sept. 5, 2 cases.

SMALLPOX—INSULAR.

Philippines: Manila, July 18-Aug. 1, 2 cases.

SMALLPOX—FOREIGN.

Belgium: Brussels, Aug. 22-29, 1 death.

Colombia: Bocas del Toro, Aug. 25-Sept. 1, 2 cases.

France: Paris, Aug. 15-22, 1 death.

Great Britain, Leeds, Aug. 29-Sept. 5, 6 deaths; Liverpool, Aug. 22-29, 7 cases, 1 death; Manchester, Aug. 22-29, 1 case.

India: Calcutta, Aug. 8-15, 6 deaths.

Italy: Rome, May 23-30, 1 death.

Mexico: City of Mexico, Aug. 23-30, 6 cases, 4 deaths; Vera Cruz, Aug. 29-Sept. 5, 2 cases, 1 death.

Russia: Moscow, Aug. 16-22, 1 case; Riga, June 1-30, 13 deaths; St. Petersburg, Aug. 16-29, 18 cases, 1 death; Warsaw, Aug. 8-22, 5 deaths.

Spain: Barcelona, Aug. 1-15, 7 deaths.

Switzerland: Geneva, Aug. 21-28, 1 case.

Turkey: Constantinople, Aug. 23-30, 1 death; Smyrna, Aug. 8-30, 109 deaths.

YELLOW FEVER.

Colombia: Panama, Aug. 31-Sept. 7, 2 cases, 1 death.

Costa Rica: Limon, Aug. 27-Sept. 3, 2 deaths.

Mexico: Monterey, Sept. 13, present; Nuovo Laredo, Sept. 15, 1 death; Tampico, Aug. 22-Sept. 5, 3 deaths; Vera Cruz, Aug. 29-Sept. 5, 50 cases, 19 deaths.

PLAGUE—UNITED STATES.

California: San Francisco, Aug. 9-21, 2 deaths.

PLAGUE—INSULAR.

Hawaii: Hilo, Sept. 14, 1 death; Honolulu, Sept. 1, 1 death.

Philippines: Manila, July 18-Aug. 1, 6 cases, 6 deaths.

PLAGUE—FOREIGN.

Africa: Cape Colony, July 19-25, 1 case.

China: Hongkong, July 25-Aug. 1, 10 cases, 6 deaths; Inkow, Sept. 7, present.

Egypt: Alexandria, Aug. 8-14, 8 cases, 6 deaths; Damiette, Aug. 8-14, 2 cases, 2 deaths.

France: Marseilles, Sept. 13, present.

Japan: Yokohama, July 25-Aug. 15, 1 death.

Mauritius: June 5-July 2, 5 cases, 5 deaths.

New Caledonia: Aug. 13, 26 cases, 18 deaths.

Straits Settlements: Singapore, July 18-Aug. 1, 3 deaths.

CHOLERA—INSULAR.

Philippines: Manila, July 18-Aug. 1, 15 cases, 14 deaths; Provinces, July 18-Aug. 1, 2,141 cases, 1,488 deaths.

CHOLERA—FOREIGN.

India: Calcutta, Aug. 8-15, 10 deaths; Madras, Aug. 8-14, 2 deaths.

Straits Settlements: Singapore, July 18-25, 39 deaths.

Turkey: Baalbeck, Aug. 22, present; Damascus, Aug. 22, present; Hama, Aug. 22, present; Tripoli, Aug. 22, present.

The Journal of the American Medical Association

Published under the Auspices of the Board of Trustees

VOL. XLI. CHICAGO, ILLINOIS, OCTOBER 10, 1903. No. 15.

Addresses.

THE EVIL OF EPONYMS.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON LARYNGOLOGY AND OTOLOGY, AT THE FIFTY-FOURTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION AT NEW ORLEANS, MAY 5-8, 1903.

GEORGE L. RICHARDS, M.D.

FALL RIVER, MASS.

As Chairman of the Section on Laryngology and Otology of the American Medical Association, I bid you, the members of this Section, a most cordial welcome to the Fifty-fourth Session of this Association and to the Fifteenth Session of this Section. The secretary, Dr. Barnhill, and myself have labored for some months in the preparation of the annual feast, and I am sure that the menu which we have now ready for you will be in no way inferior to the banquets which we are accustomed to enjoy. For many years the papers which have been read before this Section of the American Medical Association have not been surpassed by the papers presented in the meetings of any of the special societies in the United States; while this Section has the great advantage that it has no red tape attached to it, but is open to every earnest worker in the field of laryngology and otology, the only requirement for admission being that of membership in the American Medical Association. Furthermore, each paper read has the advantage of publication through THE JOURNAL of the Association, which is to-day the largest, both in size and circulation, of any medical journal in the country. So, it seems to me, that membership in this Section is to be sought and estimated as a privilege by all workers in laryngology and otology, and especially by those workers in this field who are not at the present time fellows of any of the special societies.

It is customary at this time for the chairman to make a brief report of the general progress in his department for the preceding year. This was most ably done last year by my predecessor, Dr. Makuen, but, unfortunately, events have been such that I am unable to present to you any such review. I accordingly invite your attention for a few moments to a subject which I have not as yet heard discussed to any extent in any Section, yet which seems to me to need ventilating. I refer to the growing tendency with the advance of medicine and surgery to associate methods of treatment, and especially operations, with the names of their real or supposed originators, and to describe them under the heading of this or that person's operation or method of treatment. Laryngology and otology is not so great a sinner in this regard as some of the other specialties, yet we are far from guiltless, and much confusion results from this, the reader or auditor often being in doubt as to exactly what is meant by the particular operation described under someone's name.

It seems to me that a surgical operation should be described in anatomic terms, and a medical procedure or method of treatment in language sufficiently clear so that any physician familiar with the ground principles should know what is meant. The surgeon is expected to know his anatomy, but it is too much to expect him to remember every operation and to have a clear picture of it when it is referred to under the name of its originator. By the time Jones' operation has been two or three times modified by Smith and Brown, and is then inaccurately described by Robinson, who refers to it as Jones' operation, Jones himself would probably deny it as his child. If every operative procedure were described in anatomic terms, no confusion could arise, and the reader of an article would know exactly what was meant by the author. It might take a few more words now and then, but this would be more than compensated for by the clearness of description which would of necessity result. I very much doubt whether the members of the Section now present would care to take an examination on all of the following procedures, and yet these are terms which are used as descriptive of operations and methods in use in our specialty, and all of which I have culled in a cursory examination of some recent laryngologic and otologic literature. Furthermore, I am inclined to think that if we should all give our ideas in regard to them according to the mental picture which we have of the individual operation or procedure there would be much variation in the descriptions:

Schäffer's operation on frontal sinus.
Jansen's operation through the antrum.
Cooper's method of operating on the antrum.
Boenninghaus' operation on the antrum.
Walker Downey plan of closing frontal sinus wound.
Jansen's operation for removal of orbital roof.

Nebinger-Praun operation.	Zaufall's operation.
Mikulicz's operation.	Panse's flap.
Ogston-Luc operation.	Körner's flap.
Luc operation.	Schwabach's test.
Caldwell-Luc operation.	Rinne's test.
Killian's operation.	Weber's test.
Küster's operation.	Bezold's triad test.
Czerny's operation.	Asch operation.
Löffler's operation.	Roe operation.
Betzold's mastoiditis.	Sokolowsky's operation.
Schwartze's operation.	Watson-Gleason operation.
Hessler's operation.	Ingall's operation.
Stacke's operation.	Meyer-Asch flap operation.
Schwartze-Stacke operation.	Watson-Gleason flap operation.
Freudenthal emulsion.	

These examples could be multiplied much farther, but that is hardly necessary. We have all been sinners in this regard, and, to a certain extent, must be, since various procedures, such as Politzerization, Rinne's test and Meniere's disease, have acquired a place in the litera-

ture of medicine which is permanent. Even some of these names are wrongly used. What is described in literature as Meniere's disease does not, as a rule, correspond except very remotely to what was originally described by Meniere as labyrinthine vertigo due to hemorrhage in the labyrinth.

I wish, therefore, to emphasize the plea that in the papers which we write we describe procedures as such. It will make our literature always comprehensible to the next generation as well as to our own and add much to the accuracy of our work.

In conclusion, I welcome you all once more, and hope that in the ensuing discussions the remarks will be confined directly to the topic as treated by the reader rather than wandering off in the discussion of the general subject.

THE FIELD OF THE SECTION ON HYGIENE AND SANITARY SCIENCE.

CHAIRMAN'S ADDRESS BEFORE THE SECTION, AT THE FIFTY-FOURTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION AT NEW ORLEANS, MAY 5-8, 1903.

HENRY M. BRACKEN, M.D.
MINNEAPOLIS.

The question may reasonably be raised as to whether sanitary science should have recognition through a section in the American Medical Association. The answer, I think, must be in the affirmative.

Assuming this to be the fact, the next question is as to the function of the Section, and to this the answer should be: To look after those matters that have a specific bearing on sanitary science and hygiene. This would appear to embrace questions pertaining to vital statistics, water, sewage and other topics of like nature. The fact must not be lost sight of that these topics are fully considered by various sanitary bodies, such as the American Public Health Association, the Conference of State and Provincial Boards of Health of North America, etc. This Section should be working in harmony with these strictly sanitary associations.

I take it that matters pertaining strictly to preventable diseases should be dealt with in the Section on Practice of Medicine, rather than in this Section, otherwise there would be two divisions of medical topics, viz.: preventable and non-preventable diseases. Were this true the Section on Practice of Medicine would truly be in a sad plight, or there would be the lapping over of sectional work. This has been true in the past. Smallpox, during the past few years of this Association's work, has been discussed in the sections on medicine, on sanitary science and on skin diseases. Other diseases, such as tuberculosis, pneumonia, typhoid fever, etc., have been discussed in different sections. While to a certain extent this may be unavoidable, as a general principle it is decidedly faulty. The discussion of any one topic in different sections fails to secure full consideration because those interested in the subject are separated by sections. If a specific time could be set for any given paper in a section and this time be definitely known by all members of the Association, the objection to discussing one topic in various sections would be minimized, for members might go from section to section, following the subjects in which they were interested, but such a plan in this Association is quite impossible.

I take it as a recognized fact that all physicians who are sanitarians should be medical men, or at least interested in general medicine. If this is true every medical man in this Section should register in the Section on Practice of Medicine. If he registers in that Section he should attend it. What is to be gained by a small party of specialized medical men sitting together in this room to discuss a broad subject like that of tuberculosis or typhoid fever while the great body of medical men are discussing the same subject in one of the largest and most important sections of the Association—that on medicine? If we have anything good to say on the subject the general medical man should hear it. The general medical man can not discuss these or other subjects relating to preventable diseases without saying something which every sanitarian should hear.

I would suggest that in the future the work of this Section should be concentrated as much as possible on strictly sanitary or hygienic subjects. This work could be easily covered in two days.

The chairman of this Section should make it a point always to keep in touch with the chairman of the Section on Practice of Medicine. So far as possible, subjects relating to communicable diseases should be so arranged on the program of the Section on Practice of Medicine as not to conflict with sessions of this Section. The program has been so planned this year between Dr. Thayer, chairman of the Section on Practice of Medicine, and myself as to give a day in joint session. The subjects assigned for that day—typhoid fever, plague and yellow fever—are truly of as much interest to the sanitarian as to the medical practitioner. There are other subjects on the program of the medical section which should interest us, such as dysentery.

If we wish to become narrow in our studies as specialists we will organize ourselves into a little mutual admiration section. If, on the other hand, we wish to pursue the course that will be of greatest benefit to the profession, we will seek to be recognized as medical specialists thoroughly in touch with the great body of medical men. I hope all here will agree with me that the latter is the better course for us to follow.

APPENDICITIS FROM THE STANDPOINT OF THE GYNECOLOGIST.*

HENRY P. NEWMAN, A.M., M.D.
CHICAGO.

In general, the diagnosis of appendicitis is not difficult to-day. Scarcely a decade and a half ago we were either losing the severe cases as acute peritonitis or inflammation of the bowels, or nursing them through the more protracted stages of typhlitis or perityphlitis, while the mild catarrhal cases were regarded as attacks of cholera morbus or congestion of the bowels. To-day the laity are almost as alert as the practitioners to recognize even the premonitory symptoms.

When we meet exceptions to this rule, the case is apt to be one associated with or simulating disease of the pelvic organs in the female. A case in point is one which was brought to my attention recently. A young girl of about sixteen years of age, healthy in appearance, but nervous and slightly anemic, suffered from recurrent attacks of pain and soreness in the lower abdomen.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. A. Palmer Dudley, H. P. Newman and J. H. Carstens.

These attacks occurred every three or four weeks, and were associated with the menstrual period. The distress would last but a few days, and this, the periodicity and her age, led her father, a physician, to bring her to me for gynecologic treatment. On examination I was unable to locate any disease of the genital organs, but made out, I thought, an offending appendix, and so informed the physician. Being a good all-round diagnostician and something of a surgeon himself, he had made his own conclusions, based on the prominent symptoms, and was not satisfied with the diagnosis. He took his daughter home, but later returned to the city, this time to consult a prominent surgeon. He did not fully verify my diagnosis, giving as his opinion that exploratory work should be done; that while the appendix might be involved, the principal trouble must be in the generative organs. The case went on for some months, but was finally operated on, and the appendix was found elongated, inflamed and attached at its extreme distal end to the right ovary. There was no other pelvic lesion.

The congestion incident to ovulation and the menstrual function was probably the cause of the lighting up of these exacerbations of catarrhal appendicitis, the supposed dysmenorrheal attacks being simply appendiceal colic.

After removal of the appendix, there was prompt and complete relief of symptoms. The case is interesting because of the pronounced symptomatology calling for relief, and because of the unusual attitude of the consultants, each one excluding his own specialty, the gynecologist diagnosing a surgical, and the surgeon a gynecologic disease.

This is only one of many cases in which the diagnosis of pelvic and appendiceal lesions may be obscured. In the opinion of some writers, differential diagnosis before operating in pus cases is not so very important as the indications are the same in either case. This is the view of Rostovzeff[1] of St. Petersburg, who insists on great care in examining the entire pelvic field at the time of operating. In salpingitis look for an inflamed appendix, in appendicitis look for disease of the adnexa. This is wisdom itself, but does not, it seems to me, compensate for the lack of an intelligent, clear diagnosis before operating.

The same author calls attention to the intensity of the infection caused by pus from an abscess in the appendix as compared with that from pyosalpinx. In his experience, general peritonitis due to appendicitis was invariably fatal, whereas a number of cases of general peritonitis originating in the genital organs terminated favorably.

Confusion in diagnosis may arise from the different localities in which the appendix is to be found. Its frequency in the pelvic basin has led to a distinct classification by Poncet and Dormoy of pelvic appendicitis. This nomenclature is not to distinguish it pathologically from appendicitis in any other locality, but to suggest the rational surgical treatment which should be through the vagina or rectum. Delore[2] cites some unusual instances of large collections of pus low in the pelvis, due to a diseased appendix, and evacuating through the rectum or vagina.

Downes[3] reports numerous cases of mistaken diagnosis in cases of appendicitis in the female.

Cumston[4] has had some interesting cases in which concomitant symptoms of appendicitis and tubo-ovarian diseases made diagnosis difficult, and says: "I could quote a number of other instances where lesions of the adnexa were taken for appendicitis." Deaver[5] says that in pyosalpinx due to appendicitis the symptoms are those of appendicitis in the pelvis, with dysmenorrhea and irregular menstruation. There is no history of gonorrheal infection and no indurated feeling of the vagina.

The work which Peterson is doing in this line is careful and accurate, and his further contribution will be received with attention. His first article[6] reports eighty-seven cases of abdominal section in nearly all of which the appendix has been examined as a routine procedure. At first it was examined, reported normal or abnormal, and removed only when diseased. Later it was removed as a routine practice whenever warranted by the condition of the patient. In his last thirty-four consecutive cases, the appendix was thus removed, and in just half this number, seventeen cases, was it found diseased. His collecting and tabulating of cases is specially instructive to the gynecologist, since the work was done with the idea of throwing light on the relation between appendicitis and pelvic disease, and he excluded from the clinic as nearly as possible all those cases where the diagnosis of pelvic disease was not absolutely clear. "Whenever," he says, "it was suspected that the primary focus was situated in the appendix the case was referred to the surgical clinic."

It therefore follows:

1. That the abdomen should be examined in all important pelvic cases and vice versa.

2. Functional disturbance in the pelvis may produce disturbance in the neighboring abdominal viscera.

3. In opening the abdomen for pelvic disease the appendix should always be examined.

4. If catarrhal, adherent or containing concretions, it should be removed.

5. It is not sufficient to break up or separate adhesions of an attached appendix.

6. As the macroscopic examination of the appendix is not always conclusive, its removal or "prophylactic appendectomy," when the abdomen is already open, should be determined by the best judgment of the surgeon and the condition of the patient in each individual case.

7. Any appendiceal or localized peritonitis may be an active factor in the immediate or remote production of intestinal obstruction. Strangulated intra-abdominal hernia has occurred as a result forty years after the primary lesion, and with entire freedom from symptoms during the long interim.

8. In opening the abdomen for intestinal obstruction the appendix and pelvic viscera should be looked to for the cause of trouble.

9. In removal of the appendix the invaginating operation should be done, or such other painstaking work as all intraperitoneal affections demand, to protect the wounded surfaces from subsequent adhesions.

10. The frequency of implication of the appendix by contact with diseased pelvic genital organs (Kelly cites twenty-seven adherent appendices in one hundred hystero-salpingo-oöphorectomies, and the figures of Peterson correspond) renders important not only the early removal of pus tubes, infected cystic tumors and the like, but also after operations where the appendix re-

mains, its careful protection from any possible denuded peritoneal surfaces or involved areas.

11. Barring the greater liability of infection from neighboring viscera and the somewhat greater difficulty of differential diagnosis in the female, we have more available means of exploration, a better prognosis and greater facilities for operative and non-operative relief.

100 State Street.

DISCUSSION.

DR. E. REYNOLDS, Boston—We are all familiar with the class of cases in which the symptoms are not in keeping with the results of the physical examination; cases in which neurasthenia, malnutrition and marked digestive troubles are associated with occasional moderate or even severe pain in the right side, and yet we can not feel anything distinctly. Our course of action must be guided by the degree of the symptoms presented. If the patient's health is ruined by her condition, her case justifies an operation. If she is not suffering seriously from the symptoms we are not justified in operating unless we can make a definite diagnosis. I have had a number of cases lately in which the conjunction of symptoms pointed very strongly to appendicitis. I have come to associate the conjunction of even moderate tenderness on the right side, with right-sided pain, intestinal flatus and usually some mucus in the dejections, especially if associated with a history of nausea, vomiting in pregnancy or menstrual sick headache, with appendicitis. The presence of a majority of these symptoms is very strongly suggestive of chronic conditions of the appendix. Beyond question we are all removing the appendix to-day more frequently than we did two years ago. And I am inclined to think that we shall remove it still more frequently in the future. I believe that we should remove every abnormal appendix, but I think we are going too far when we advocate its invariable removal. I think it is worth remembering that we have all been doing many abdominal sections for many years without removing the appendix, and I should be curious to know how many operators there are in this room who have had many cases where they have operated and have not looked at the appendix in which that appendix ever gave trouble afterward. The last case I operated on showed a condition of the appendix that I have seen a number of times. In these cases the ligament which originally forms the mesentery of the appendix, the iliolumbar ligament, which in the primitive state also forms the mesentery of the colon, and the mesoovarium, persisted in its fetal state, and the symptoms were apparently referable to the persistence of this ligament. In the last case it caused a kinking of the appendix and connected it with the right kidney. The more we study the anatomic conditions of these chronic appendiceal cases the more we shall get at the bottom of them, their causes and their treatment.

DR. EDWIN RICKETTS, Cincinnati—To say that we can in all of these cases differentiate, is, I think, putting it rather strong. I agree with the previous speaker that to say that in all instances in which the abdomen is opened the appendix should be removed is a step too far in advance. In many cases in which the right ovary or tube is attached to the appendix we have a train of symptoms that is rather peculiar, but in many of these cases I am certain that we can make a diagnosis. It is an attack of inflammation that is peculiar to the appendix.

DR. WM. W. WATHEN, Louisville, Ky.—We are discussing the relation of appendicitis to disease of the pelvic structures, particularly of the ovaries and tubes. I can not concur in an opinion that connects the occurrence of appendicitis with an ovary and tube where the anatomic and physiologic conditions are normal. Hence when we have appendicitis arising in the pelvis we must have some pathologic condition that causes it, although the pathologic condition may have been so modified that it is observed with difficulty. Recently I removed the appendix in about eight cases of disease of the pelvic structures, and in each the diseased condition was caused by pus in the right side of the pelvis. In none was there any pus in the appendix, only a parenchymatous thickening and adhesions. In every laparotomy I feel that it is the duty of the operator to examine the appendix, and if it is at all diseased it should be removed, especially in pelvic inflammations, because appendices which are diseased as the result of a pelvic inflammation are long appendices that will again fall down, come in contact with the pelvic organs, and possibly become more inflamed. I do not believe, however, that a healthy appendix of usual length should be removed.

DR. PAUL MICHINARD, New Orleans— The question of appendicitis is one that interests me as a gynecologist, not from the operative phase, but from that of diagnosis between salpingitis and appendicitis. Any man with a certain amount of diagnostic skill can diagnose acute salpingitis from acute appendicitis, and any good gynecologist can do an appendectomy as well as a salpingectomy. But the question is, shall we tell the patient that he has a chronic right-sided salpingitis or a recurrent appendicitis? In the former case she is practically in no danger, but in the latter case there may be an acute gangrenous appendicitis that may at any time cause death. In chronic appendicitis the most intense pain is produced by pressure on the abdominal wall; in chronic salpingitis, in the right fornix, pressing with the finger in the vagina. Tumefaction in the first, by pressure on the abdominal wall; in the second, by firm pressure in the right vaginal fornix. We are more interested in the diagnosis than in the operation which we can all perform.

DR. WM. P. MANTON, Detroit, Mich.—I wish to endorse Dr. Newman's paper fully. In many cases it is difficult to make a differential diagnosis. Often where there is no active salpingitis or appendicitis there may be an adherent appendix. You will invariably find a thickening on the right side and without difficulty can trace the adhesions up from the right fossa to the appendix, and also get a certain amount of impaired mobility of the cecum. No man, unless he has had a very large experience in abdominal surgery, is capable of saying from the macroscopic appearance of the appendix whether it is healthy or not. The idea that a normal-looking appendix should be left because attached only by very fine cobweb adhesions to the broad ligament or glued to the intestine, is absurd. For some years I have had nearly all appendices which I have removed examined microscopically, and in the vast majority of cases appendices which from their macroscopic appearance might be said to be normal, were found diseased when sectioned and examined. The mucous coat, and even the muscular coat, may be ulcerated through, and sometimes in imminent danger of rupture, when to naked-eye view the appendix appears perfectly normal. I believe that Dr. Newman is right when he advocates the removal of every appendix that is in any way connected with disease of the right appendages. Microscopic examinations will show that often when the organ appears to be normal it is in reality very much diseased.

DR. CHAS. S. BACON, Chicago—I failed to hear any reference to the relation existing between appendicitis and obstetric complications. I believe that the obstetric side can not be omitted. The most important feature of the paper was the question of diagnosis. In appendicitis the question of the existence of pregnancy in its early stages is extremely important. After the pregnancy is established then the diagnosis between a complication of appendicitis and other forms of peritoneal inflammations is important. Pain is not so good a diagnostic point in the pregnant as in the non-pregnant state.

DR. J. H. CARSTENS, Detroit, Mich.—The whole question seems to be revolving around the diagnosis. If we have an acute case of salpingitis, with uterus fixed and an exudate in the pelvis, there is no question about its being a pelvic cellulitis. We do not have that with appendicitis. When there is pain over the McBurney point in acute inflammation of the appendix then we have a uterus which is freely movable. Dr. Newman's paper referred to chronic cases in which there is no exudate in the pelvis; hence there can be no acute salpingitis. There is a certain amount of pain over the McBurney point, which there never is in salpingitis. When I get cases in which I do not know whether the tube or the appendix or both are diseased, but in which there is pain over the

McBurney point and a sudden squirming of the patient when she is touched, I insist on operating. Ordinarily with young people who go along without any particular trouble, and who suddenly develop a little pain in the right side, recurring every day or week, one can be almost positive that it is a case of appendicitis which requires an operation.

Dr. C. O. Thienhaus, Milwaukee, Wis.—I have pointed out in a published paper that in many cases of chronic catarrhal appendicitis one may find, clinically, dysmenorrhea and not so seldom shortening of the right broad ligament, inflammation of the right tube, with or without hydrosalpinx and inflammation of the ovary. The essential question in such cases is: Was the tube the primary focus of the infection and the appendix involved secondarily, or vice versa? I believe that in many cases in young girls which present the above symptoms and in which gonorrhea can be positively excluded the appendix was the primary seat of the malformation present and the female genital organs involved secondarily. It has been stated in literature that one very often finds paraovarian cysts, pelvic inflammatory cysts and ovarian cysts connected with chronic appendicitis. What is the reason? I believe that in general the appendix is a *locus minoris resistentiæ*, and that in many cases of inflammatory condition of the female genital organs on the right side the appendix becomes involved. I found an ovarian cyst in a woman three months pregnant who was lying in bed for two months with a diagnosis of appendicitis. On examining her I found a tumor in the pouch of Douglas of the size of a man's fist and made the diagnosis of ovarian cyst, explaining the clinical symptoms by twisting of the pedicle. At the operation I found a cyst with a long pedicle, which was not twisted nor showed signs of any previous twisting, but the appendix about 14 cm. long was adherent to the cyst and thrown around it at the point of connection of the cyst with the pedicle. There was prompt recovery after removal of the appendix and cyst and pregnancy was uninterrupted. In cases connected with abscesses in the pouch of Douglas one may encounter the greatest difficulties in regard to diagnosis.

Dr. J. Wesley Bovée, Washington, D. C.—We are getting a little too radical. I am sorry that Dr. Carstens brings in McBurney's point. I have found the cecum low down in the pelvis many times and I can not make the McBurney point chase the cecum all over the peritoneal cavity. Therefore, to rely on pain over the McBurney point as a symptom of appendicitis is an error. Another error is the practice of removing the appendix of every case in which we operate on the adnexa. I have repeatedly operated on cases such as ruptured tubal pregnancy, dermoid cysts, etc., in which I did not look at the appendix as I did not dare to take the time. In other cases I take enough time to look at the appendix, not to remove it. I remove it whenever the condition of the patient will permit, but there are cases in which it can not safely be done.

Dr. G. Betton Massey, Philadelphia—Since no mention is made as to whether the operation could have been avoided by medical treatment, we must conclude that the operation was necessary. I had a case recently that leads me to think that here, too, there is a chance for conservatism in the treatment of conditions where circumscribed colitis may be mistaken for appendicitis or salpingitis. The case was that of a young girl, very much run down in health, and very nervous. No abnormal physical conditions were found. The treatment that seemed to do a great deal of good was betanaphtholate of bismuth, though operation had been advised. I call your attention to the wisdom of treating the colon when you suspect that you have appendicitis, which is often an extension of a colonic trouble. Treat the colon, the original site of true appendicitis. It has been the result of my observation that many people with colonic irritation are passing their lives in ignorance of the fact, and it is probable that appendicitis is frequently a sequel of this condition.

Dr. J. L. McCollum, Chicago—I believe that there are cases in which no one can make a diagnosis. In cases in which we can demonstrate that there is no change in the tube and ovary we can exclude pelvic trouble; and in cases in which there is no decided tenderness over McBurney's point, no rigidity of the recti, we can exclude appendiceal trouble. I saw a young girl in consultation, and did not concur in a diagnosis of appendicitis made by one surgeon. The history apparently excluded any pelvic trouble. We operated and found that the appendix was normal but the tube diseased. We can not make a positive diagnosis in these cases because the findings are so contradictory. I am heartily in accord with the dictum to remove every appendix whenever possible. If I have the patient's consent, and if her condition will permit, I remove the appendix, even when I am doing a herniotomy. I have had no occasion to regret my radical procedures in this field, and the patients have always been satisfied with the result.

Dr. F. F. Lawrence, Columbus, Ohio—We are apt to forget that Nature is sometimes a very good physician. In cases of chronic peritonitis, tubercular or otherwise, in which it is necessary to open the abdomen, the separation of the adhesions is followed not only by relief of the symptoms within the peritoneal cavity, but if for any reason it is necessary to reopen the abdomen after some months, we find no sign of the former disease. That this also holds good in cases where we find peritoneal adhesions without pathologic conditions of the appendix, where we are operating for a right-sided tubal trouble, is undoubtedly true. I do not believe that the author intended to advocate the removal of normal appendices. No abdominal surgeon would presume to know more about what is good for man or woman than the Almighty who made them. We are assuming too much by removing such an organ which is doing no harm. Any diseased condition should be removed; normal structures, whatsoever they may be, should be left alone.

Dr. D. H. Craig, Boston—Four cases that have recently come under my notice are examples of the existence of the fold of the broad ligament constituting the lumbo-ovarian or appendiculo-ovarian ligament of Clado, and in three of the cases the presence of this structure was not suspected but was found during operations for other pelvic lesions. In the last case the operation was done with the distinct understanding that a definite diagnosis had not been made. Previous treatment for both ovarian conditions and appendicitis was of no avail. She was not an invalid, nor was she well. The right broad ligament was found to be divided into three folds: one carried the round ligament, one the tube, and the third the ovary. This latter extended nearly to the tip of the appendix, constituting the mesoappendix. Through this division of the ligament came the ovarian artery from some point high up behind the cecum. I did not feel justified in tracing it any farther. On the left side there was a mere rudimentary broad ligament low down, the round ligament, tube and ovary being entirely absent. The organs present on the right side were entirely normal. The question throughout the case had been one of diagnosis between appendicitis and salpingitis. The appendix and ligament were removed. The ovary was apparently normal and was not removed. The lower segments of the broad ligaments were thus perfectly relaxed and were not disturbed. The patient made a good recovery and is entirely free from pain.

Dr. H. P. Newman—My purpose in introducing this subject was to suggest to both surgeon and gynecologist more alertness in the handling of these cases. Appendicitis should not be regarded as a simple affection that may be neglected with impunity. I have seen fatal complications arise from its presence even forty years after the primary attack. If there is any pathology in the appendix, and if the patient's life would not be endangered by its removal, it should not be left in the abdomen after laparotomy. As I have stated, the pathology is not always discernible by the naked eye, and the macroscopic examination is not always conclusive, so that whenever the abdomen is opened a prophylactic appendectomy should be considered and its performance determined by the best judgment of the surgeon. Some one has asked in regard to the prevalence of appendicitis with infected ovarian cysts and twisted pedicle. I referred to this in my paper. It is not uncommon, and I insisted on the removal of infected cysts as I would the removal of infected tubes or any other infection of the pelvis.

THE DEVELOPMENT OF THE FUSION CENTER IN THE TREATMENT OF STRABISMUS.*

NELSON MILES BLACK, M.D.
MILWAUKEE, WIS.

The etiology of strabismus is a still much-mooted question, and each ophthalmic surgeon follows out a routine of treatment with his cases according to the theory which seems to him most rational. As the title indicates, defective development of the fusion center will be considered the essential etiologic factor in this paper, according to Worth's[1] theory.

De Schweinitz's[2] new book gives the following factors as causative:

1. Disturbance of the relation between accommodation and convergence by errors of refraction.
2. Disparity in the length, thickness and tension of opposing muscles.
3. Inequality in the vision of the two eyes or amblyopia of one eye, which removes the natural stimulus of diplopia to exact convergence.
4. Disturbances of innervation and defective development of the fusion faculty.

Savage[3] says, under the etiology of comitant esotropia: "The conditions causing the error exist from birth, and only one out of several natural causes undergoes any change at any time after birth. . . . That in the greater number of cases . . . over-stimulation of the third conjugate innervation center causes an actual deviation . . . a conversion of esophoria into an esotropia, and throws the immediate blame for crossing of the eyes on the ciliary muscles."

The following etiologic factors are also given in the order of their importance:

1. Esophoria.
2. Hyperopia.
3. Hyperphoria of one eye and cataphoria in the other.
4. A lower state of visual acuity in one eye than the other, either from congenital abnormality in the perceptive, transmitting, or receptive part of the apparatus or some opacity or irregularity of the refractive media, either congenital or the result of disease or anisometropia.
5. "The whole macula in one eye may be connected with one side of the brain, while the whole macula in the other eye may be connected with the other side of the brain."

And though Savage[3] remarks, "there is no test in the investigation of comitant esotropia so important as the fusion test," and lays so much stress on the training of the fusion faculty in its treatment and has determined the nine conjugate innervation centers of the extrinsic eye muscles, he does not come out and avow a fusion center.

"Vision[4] is the mental interpretation of an impulse conducted from the rods and cones of the retina through the optic nerve and tracts to the visual areas of the brain." Man being a binocular animal must, in his normal condition, receive two sets of sensations from any luminous object; these are transmitted to the visual areas of the brain; from there they must, in the normal state, be transmitted to a co-ordinating center, or, as I shall call it, the fusion center, where they are blended; here binocular vision becomes binocular single vision. In order to allow of a blending or a fusing of these two sets of sensations, identically corresponding portions of the retinæ of the two eyes must be influenced by the pencil of light; this requires binocular fixation.

To perform the normal function of seeing, then, we must have:

1. A normal perceptive apparatus, i. e., emmetropic eyes.
2. Perfectly balanced extrinsic muscles.
3. Normal transmitting apparatus.
4. Perfect receptive apparatus, and, finally,
5. A fully developed fusion center.

From this center must emanate all the efferent impulses to the various subsidiary centers for all changes in the accommodation, direction of the visual axes and positions of the head and body that are required to bring corresponding retinal points into focus; hence, when the development of this center, or its function after development, is in any way disturbed or interfered with we have as a result those deviations of the visual axes known as heterophoria and heterotropia, or strabismus; not due to abnormalities in the anatomic relations of the orbit and muscles and paralyses of the same.

Worth[1] has determined that the fusion center is fully developed in the normal individual by the sixth year.

The fusion center may be entirely wanting; it may be in a rudimentary state, due to non-use from various external causes or by being rudely interfered with in its developmental period by fright or some prolonged or severe illness.

Absence of the fusion center is evidenced in those not rare cases of true alternating strabismus, which, even after all methods of treatment have been tried, can never obtain binocular single vision, and some not even binocular vision. Though the visual axes may appear perfectly parallel, the vision in each eye normal or made so with correction, they can never fuse, but rapidly fix, first with one eye then the other.

The following conditions interfere with the development of the fusion center:

1. Refractive errors.
2. Inequality in the sight of the two eyes.
3. Faulty perceptive, transmitting or receptive apparatus.
4. Abnormal relations between orbit and muscles, their over-or-under-development and paralysis of one or more of them.

Refractive errors interfere with the development of the fusion faculty by the unequal relation between accommodation and convergence; the function of each separately has some latitude of movement, but there is a limit beyond which neither can operate alone; "thus a hyperope of 6 D. would require an accommodation of 6 D. to neutralize it, the visual lines being parallel, the point of convergence is then nearer than the point accommodated for."[2] The images carried to the brain from both eyes being blurred, that of one is disregarded by the fusion center as a clearer image is thus obtained, exactly "as[5] we disregard the image formed by its fellow when we use the microscope with both eyes open," and the eye thus left without a point of fixation turns in, that being its direction in attempting to keep up the relationship between accommodation and convergence;

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks.

1. Worth: The Etiology and Treatment of Convergent Squint, The Lancet, May 11, 1901.
2. De Schweinitz: Diseases of the Eye, fourth edition.
3. Savage: Ophthalmic Myology.
4. Suter, Posey-Wright: Diseases of the Eye, Nose, Throat and Ear.
5. Black, Nelson M.: A Plea for the Early Treatment of Squint, THE JOURNAL A. M. A., May 24, 1902.

this is the beginning esophoria which eventuates into continuous esotropia. In myopia, in contrast to this, when deviation does occur, it is usually divergent strabismus.

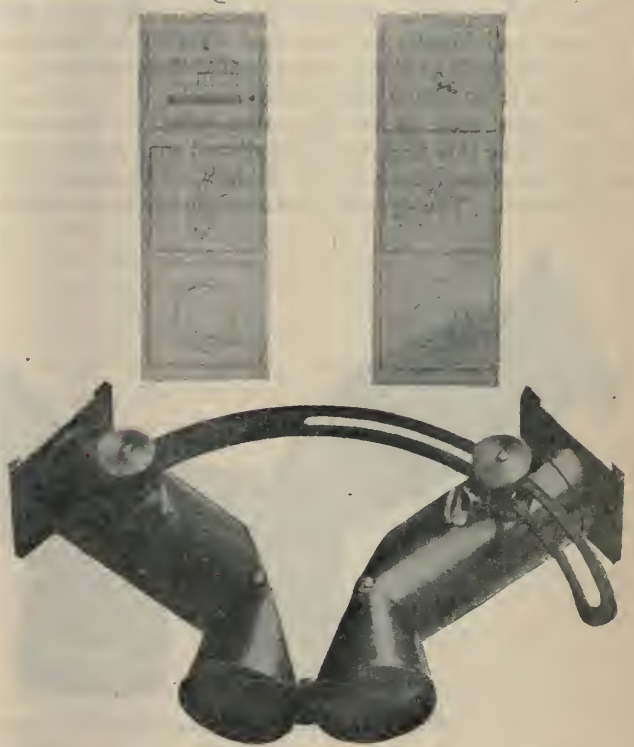
Because the sensation sent by the eye to the fusion center can not compete in distinctness with that sent by the fellow eye, in anisometropia (even if slight), congenital amblyopia, opacities of the media or faulty conductive and receptive apparatus of one eye, it is disregarded, the center develops without its influence and the eye, receiving no return impulse, has no point to fix, and, consequently, the visual axes deviate; if, however, the center has been developed before these factors appear, habit usually holds the visual axes straight afterward.

Wood[6] says of amblyopia ex anopsia: "Whatever be the origin of the defect in sight, it is probably the main cause of the heterophoria." In my opinion, amblyopia ex anopsia is not a cause of the non-development of the fusion center, but, on the contrary, a result largely of its non-development. Because of the disregard of the sensation sent by the eye to the fusion center, it does not fix, is not used; and becomes amblyopic, the amblyopia generally does not correspond to any ophthalmoscopic defect, although the visual field is frequently contracted, the error of refraction of the amblyopic eye is often much the same as that of the fixing eye, so that the ametropia can not account for the lowered visual acuity."

Anatomic abnormalities of the orbit and extrinsic muscles or paralysis of one or more of them, of course, prevent the development of the fusion center because of the impossibility of binocular fixation, but nature may try to help out the fusion center in bringing about binocular single vision, even here, by specializing other cells to form a new fovea.

Those cases of strabismus which are due to the fusion center being interfered with during the developmental stage, usually give a history of a deviation following some severe illness, convulsions, or during an attack of whooping cough, or after a severe fright; it is usually periodical at first and finally becomes constant. The eyes are usually found emmetropic or nearly so, the separate muscular movements are perfect, fixation with either eye; but only the lowest grade of binocular vision exists, or perhaps none at all. The illness or fright has interfered with the development of the fusion center for the time being and a deviation, periodic at first, appears and may remain so, not being in evidence unless the child is ill, tired or excited; or it may become constant, each visual area remaining intact and a comitant, alternating strabismus results. These cases usually respond readily to orthoptic treatment.

Development of the fusion center by orthoptic exercise is by no means a new feature in the treatment of strabismus, but many of the various forms of stereoscopes, used for this purpose, have been faulty in that binocular vision could not be obtained. Sufficient time and patience in many cases were lacking; and an amblyopic eye was not considered worth working with when a tenotomy, advancement, or combination of the two, would produce, at least, a cosmetic result at once. Landolt[7] says: "The principle of any stereoscope useful for the treatment of strabismus is that the instrument employed places the eyes in the conditions which are most favorable to the fusion of their retinal images."



6. Wood, C. A., Posey-Wright: Diseases of the Eye, Nose, Throat and Ear.

7. Landolt: Norris-Oliver Text-Book.

Worth's new stereoscope, or amblyoscope as he calls it, has overcome the first stumbling block.

"This instrument consists of two halves joined by a hinge, each half is made up of a very short tube joined to a longer one at an angle of 120 degrees; a mirror being placed at the cord subtending the arc of this angle; an object glass is placed at the free end of the longer tube, at the free end of the shorter tube is a lens, the focal length of which equals the distance of the reflected image of the object glass at the end of the longer tube. The two halves of the instrument can be brought together to suit a convergence of the visual axes up to 60 degrees, or separated to suit a divergence of as much as 30 degrees."

The writer has added to Worth's model an additional movement in a vertical direction, in order to obtain

Amblyoscope and Series of Slides.—The bird and cage being used to establish binocular vision only. The second set requiring true fusion to complete the picture. The last when fused gives an impression of the perspective.

fusion when the lateral deviation is complicated by a vertical deviation.

With this instrument, the fusion center can be exercised and developed during the existence of the squint. The fact that parents are bringing their children for treatment for strabismus at an earlier age and demanding that something be tried before an operation is resorted to, makes us take more time and use more patience; and, finally, the fact that the vision of a large majority of amblyopic eyes can be improved by proper treatment has replaced immediate and indiscriminate operating and given this department of surgery its proper place, that of producing parallelism of the visual axes after the fusion center has been sufficiently restored, to maintain binocular single vision by the use of the stereoscope and no noticeable diminution in the degree of deviation from a continuance of the treatment.

The existing conditions in a case of strabismus naturally determine the method of procedure in attempting to develop the fusion center. The first thing, however, is to determine the visual acuity of each eye. This may

be accomplished in children under 3 or 4 years of age after Worth's[1] method by means of five marbles or ivory balls, varying in diameter from one-half to one and one-half inches; if at five or six meters' distance the youngster with one eye occluded can go directly to the smallest ball thrown on the floor by the operator, it is safe to say his visual acuity is practically normal; at least, the vision of the two eyes can be compared in this manner and the question of an amblyopic eye determined. The amount of deviation of the strabismus is then determined in order to see as the treatment progresses if there is any diminution in its degree; this is accomplished with the perimeter or some of the various strabometers, or it is quickly demonstrated by the writer's[8] modification of Worth's apparatus, which is an easy and different application of the perimeter method. The ability of the various extrinsic muscles to rotate the eye is tested individually to determine whether the strabismus is the result of their over- or under-development, innervation or anatomic abnormality.

The next step is to determine whether binocular vision exists; this may be accomplished many ways, but with greatest ease, especially in children, by the use of the amblyoscope. The eyes are then subjected to complete cycloplegia; the errors of refraction, if any, determined and correcting glasses ordered.

Worth-Black amblyoscope, having vertical movement.

When an amblyopic eye exists, it is actively brought into use to determine whether its vision can be improved; this is done by instilling a mydriatic into the better member, if that is sufficient to allow the vision of the poorer eye to compete with it; if not, the better eye is occluded by a blinder or a bandage and the amblyopic eye is depended on for vision entirely. That a large majority of so-called amblyopic eyes can be improved in vision by requiring the possessor to depend entirely on them for seeing, is certainly proven by reported cases;[9] [10] in those cases in which no improvement is noted, if a visual field can be obtained, defects not visible with the ophthalmoscope may be determined, which will lead one to classify the eye as congenitally amblyopic; improvement in the vision of such an eye is almost beyond hope, still we should not give up trying until sufficient time has elapsed, with the better eye occluded, as to absolutely prove that there has been no gain in the vision of the amblyopic eye.

The development and exercise of the fusion center with the amblyoscope is commenced immediately; for this purpose three sets of object slides are used; the first are two dissimilar objects, as a bird and a cage, a mouse and a trap, etc.; these require only binocular vision. A set requiring binocular single vision or fusion has part of the subject on each slide, and must be fused to make a complete picture; the third set consists of stereoscopic pictures, which, when combined, give an impression of perspective or depth perception.

The amblyoscope is used in the following manner:

"The child with his correction on is held on the surgeon's knees and the amblyoscope roughly adapted to his degree of deviation; it is then held before the child's eyes and an electric lamp is put in the axis of each tube about four feet away. By a simple mechanical arrangement each lamp is easily brought nearer to, or put farther away from, the tube which it illuminates. A slide showing a cage, for instance, is put in the tube before the child's fixing eye, and a bird in that before the squinting eye, and the child is told what to look for. At first he sees only the cage. The lamp before the fixing eye is then taken farther away and that before the squinting eye is brought nearer until the child sees the bird. By this time he has lost sight of the cage. The intensities of the illuminations are then adjusted until the child sees both the bird and the cage. The child is then allowed to grasp the instrument and, assisted by the hands of the surgeon, is taught to vary the angle of the instrument so as to make the bird go in and out of the cage. Many other similar pairs of slides are shown. The average child of 3½ or 4 years of age takes a very keen interest in the game, which he imagines has been devised merely for his amusement. Slides which require a true blending of the images are then shown. After a time it is often found that the angle of the instrument may be altered to a very considerable extent, either in convergence or divergence, while the eyes follow the objects and maintain fusion of the pictures. One often gets a powerful "desire" for binocular vision in these young subjects with surprising facility. The next step is to equalize the intensities of the lights. This may usually be done at this stage without a return of suppression. In many cases one is able to deviate the two halves of the amblyoscope more and more at each visit until parallelism of the visual axes is obtained."

As the visual axes are brought nearer parallelism, the use of an ordinary stereoscope with the Kroll's charts, Würdemann's modification of these or those recently published by Dr. Hale of Chicago, will serve as the most practical method of exercising the fusion faculty, as they can be used with an inexpensive stereoscope for daily exercise by the patient at home.

Some cases, however, will undoubtedly require operation to bring about complete parallelism of the visual axes; but, if the desire for fusion has been established—and Worth[1] asserts it can only be acquired in early

8. Black, Nelson M.: A Simple and Effective Method of Determining the Degree of Deviation in Squint, Ophthal. Record, November, 1902.

10. Lewis: The Conservation of Binocular Single Vision, Annals Ophthalmology, January, 1903; Medicine, Nov., 1902.

childhood—it is only necessary to bring the visual axes approximately straight, because a desire for fusion, which has been acquired by the use of the amblyoscope, will then place and hold the eyes in such position that identically corresponding portions of the two retinæ are affected.

Until the etiology of strabismus is settled and universally accepted, the methods of treatment will vary with the etiologic theory accepted by the individual; however, since commencing with the above outlined treatment in February of last year, we have not operated on a case of strabismus in a child under 10 years of age, and there are now 17 cases under treatment, and all making progress, with five cases completely cured and maintaining binocular single vision without any discomfort. The objections to the method are the time required to effect the result and the possibility of having to resort to operative measures in the end; this with

Worth-Black deviometer for determining degree of deviation in squint.

the assurance, however, of binocular single vision being maintained and no relapse of the condition; the trouble of impressing the parents with the importance of coming at the time indicated for consultation and the expense of the treatment, which amounts to as much or more than an operation, and in case of an amblyopic eye, of keeping the better eye occluded for sufficient length of time to obtain a result, are the main obstacles to overcome; these objections, however, I consider of minor importance when compared with the truly remarkable results obtained.

Hydrogen Dioxid in Diagnosis of Ulcer of Stomach.—A Russian confrère is cited by a French exchange as having been able to differentiate ulcer from cancer by the intense pains that followed ingestion of a tablespoonful of a 3 per cent. solution of hydrogen dioxid. This extreme sensitiveness of the gastric mucosa to the effects of a weak solution of hydrogen dioxid seems to be an invariable accompaniment of gastric ulcer, as treatment based on this assumption always resulted in a cure in his experience. He found also that the same solution had a marked beneficial effect in cases of gastritis, arresting vomiting and disinfecting the digestive tract. He thinks it might prove particularly useful in infantile gastro-intestinal affections. The results of treatment by this means of habitual constipation from atony of the intestines have also been very encouraging.

STEREOSCOPIC EXERCISES.

WITH A SERIES OF PICTURES—TO BE USED IN AMBLYOPIA AND SQUINT.*

ALBERT B. HALE, M.D.
CHICAGO.

The stereoscope has had a history not unlike many other instruments of our day. At first developed to illustrate certain scientific phenomena, it rested as an optical apparatus in the physicist's laboratory till the enterprising spirit of commerce combined its principles with the rapidly popularized art of photography and made of the product a scientific toy. Any one of mature years can remember the time when the center ornament of the parlor table was the stereoscope and its pile of pictures—from the Alps to the acrobat—and much instruction, as well as entertainment, was afforded by the fascinating contrivance.

I dare say that many a time some one person would be puzzled to find that the stereoscope gave him no better view of the pictures than did his naked eyes, but the explanation for this—the failure of the apparatus to develop the perception of depth, which is its function—was unknown to him or his friends, nor investigated by the unscientific; it was probably attributed to some idiosyncrasy, and no more thought given to it. Gradually the popularity of the instrument waned, and to-day in many an attic or lumber-room may be found a forgotten stereoscope, with its pictures, of which the modern child knows neither the use nor meaning.

Hitherto the stereoscope had served to illustrate only a phenomenon in physical optics, and the human eye which interprets it, i. e., what we call physiologic optics, was scarcely taken into account. But when ophthalmologists began to study the problems of the human eye (vision, binocular vision, fusion, depth perception) it was not long before there was a demand for some means to test the visual sense of the two eyes working together, so that the perceptive capability of each eye could be estimated both by itself and by association with its fellow. The principle of fusion was then investigated—a cerebral function not an optical condition—and the stereoscope was seized on as the instrument most adapted for the purpose.

Dubois-Raymond, a physiologist, early saw the advantages of the stereoscope, but Javal, and later Landolt, both ophthalmologists, were the first to popularize its scientific and practical application.

I shall not explain the principles of the instrument more than to say that it is necessary to separate—isolate completely—the image of one eye from that of the other, so that it is impossible for the observer to confuse what he sees with one eye with what he sees with the other, or whether he sees with the right or the left eye. By preventing this confusion, we at once notice a distinction that is not enough emphasized by physiologists in teaching the functions of the eye. The distinction is this: One eye may see while the other does not (I do not mean amblyopia, for this is a condition to be considered later and apart), monocular vision. The eyes may each perceive a portion of the outer world and combine these portions into an image, binocular vision. The eyes may each see these portions with a true estimation, not only of their relation to each other, but also of their special relation to the observer, and thereby fuse them into a

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks.

single image with the perception of depth, binocular single vision.

Now, with a complicated apparatus and with elaborately devised charts and diagrams, it is possible to study retinal and cerebral function with pleasing exactness, and to make records of results, but the therapeutic use of the stereoscope is often hampered by such complications, because it requires the technical hand to manage them and the skilled ophthalmologist to interpret them, and because the patient is apt to become so confused at the details of the test that it is found impossible to make interesting exercises of them or to perform them at home without this skilful guidance. Exercises to be placed before the eyes of a patient arouse his curiosity; they must be such that a child may pursue them of himself and may be easily taught just what he is expected to accomplish.

European practitioners have published series of stereoscopic views which meet the best requirements of science and art, and I do not criticise them when considered as laboratory, or even office, apparatus. The French series of Hegg (Berne), used by Landolt; the German series of Dahlfeld, Kroll (Perlia), with its American reprint by Würdemann, Pflugk, the Spanish series of Presas, are all excellent in their way, but from my own experience I am convinced that they find but

Figures on a sample card of stereoscopic exercises. In use there should be 60 cm. between the centers of the two images.

limited use when given to the patient for exercises at home. Beside this, they are all (with the exception of the American reprint) published in a foreign tongue, and all have pictures strange to the American eye, or so uneasy of interpretation that the patient is often more embarrassed to give a name to what he sees than to tell simply what the picture presents to him.

Such being the case, I felt that I might benefit my own patients by publishing a series of American pictures, simplifying them as much as possible for domestic use, reserving for office tests the more complicated problems in the higher developed series; but I can not be satisfied till I have submitted them to the judgment of my confrères, who, I hope, will aid me with their criticisms to make them a more suitable and usable set for the treatment of some amblyopias and squints. I am not so enthusiastic as to believe that squint can of itself be corrected or in many cases even improved by stereoscopic exercises alone; the classical treatment, by correction of the refractive error, and when deemed necessary by operation, can not be displaced by this means; but, on the other hand, I must express my satisfaction with the results of stereoscopic exercises; and my experience runs counter to that of Gould, who miscredits the efficacy of the stereoscope in amblyopias or squints.

Stereoscopic exercises must illustrate five stages:

1. Simple tests to measure what the one eye or both eyes together can do. This I have embodied in Series A (1, 2, 3, etc.), which can be extended as far as may be desired.

2. Simple tests of the ability of each eye to see its own field and to retain this impression while the other eye also sees. This is Series B, which grows somewhat more difficult from number to number.

3. Tests in which each eye sees what it at first takes to be the same picture, but in which the half for each eye lacks some detail present in the half for the other eye; these halves are probably fused, or the patient thinks they are, but a failure to fuse can be detected by the omission from the patient's description of one or more details. This is Series C.

4. Tests in which not only is there an instinctive stimulus to fusion, but also the added factor of depth, for the figures are so arranged that each eye obtains a picture presented to it at an angle differing from the angle of the other eye, and the completed picture seen with both eyes acting together should be that of a solid body, i. e., there should be a perception of depth in addition to fusion; stereoscopy, the perfected act of binocular single vision. This is Series D.

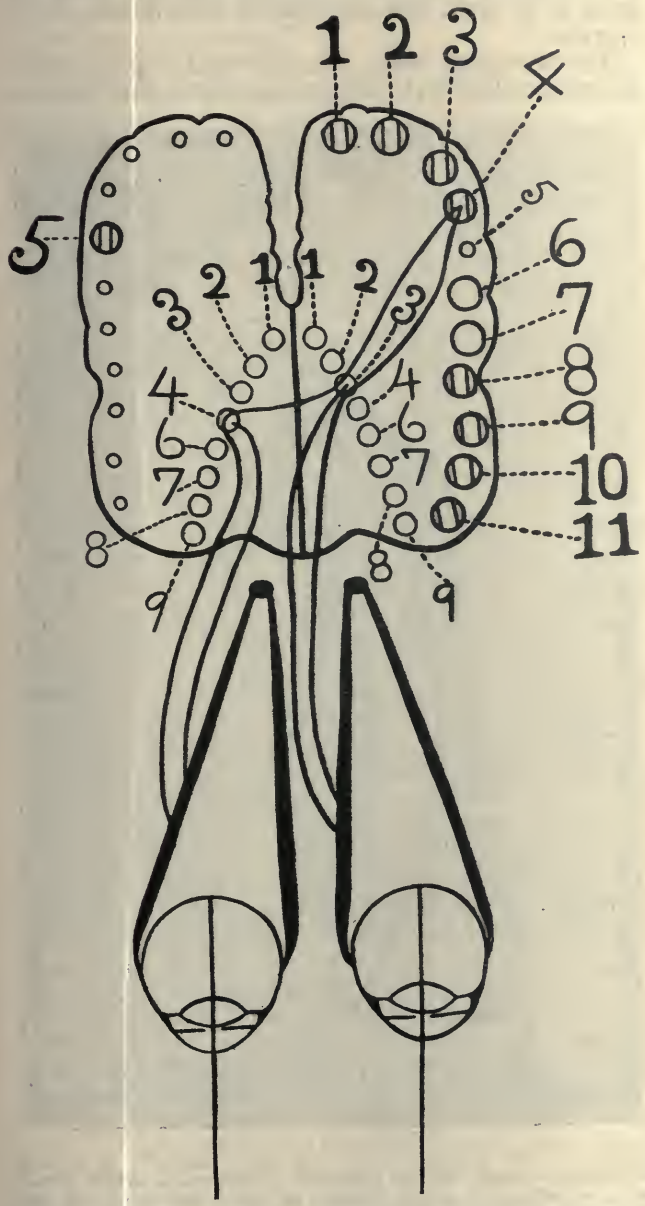
5. Tests by means of pictures of what we habitually see in the outer world, in which I have introduced two ordinary photographs from life and a simple catch card for reading, in which each eye is deprived of some letters visible to the other eye, so that both eyes must be used together and simultaneously before the story can be fluently read. This is Series E.

These charts may be placed in the hands of any child or adult, to be used at home and frequently, with regular reports to the ophthalmologist of what progress has been made. The pictures are scientific, clear, readily understood, handy and cheap. Any simple stereoscope of the shops may be used. The whole value of stereoscopic exercise depends on repetition, as it is only by this continuously repeated stimulation that the habit of fusion may be formed and perpetuated.

103 State Street.

DISCUSSION

ON PAPERS OF DRS. BLACK AND HALE.



DR. C. C. SAVAGE, Nashville, Tenn.—I would call your attention to this chart, which is one made to illustrate my own paper, but which serves well to discuss this one. Dr. Black quoted me correctly when he said that I did not avow the existence of a fusion center. I deny the existence of a fusion center in the sense in which he uses the term, and I believe Dr. Black will agree with me before I am through.

I have represented here all the centers of the brain that have to do with the movements of the eye. Two faculties preside over these. One of the faculties is volition and the other is the fusion faculty. Nature has two ways of dealing with diplopia: One is the mental fusion of the two images and the other is mental suppression of one image. Both are mental faculties. I want to say that instead of having one fusion center, we have twelve at the base of the brain and two in the cortex.

I have these centers marked off here so as to indicate which are under the control of the fusion and which the volitional faculty. The ones crossed with parallel lines are volitional; the others, not so crossed, are under the control of the fusion faculty. The volitional centers are all in the cortex, while those under the control of the fusion faculty are situated mainly in the base, there being only two of these in the cortex. The basal centers are all fusion centers. Every one of them is presided over by the fusion faculty of the mind. There are just a few of these centers concerned in the condition that Dr. Black has spoken of—esotropia. The third basal center on either side has nothing to do so far as esotropia

is concerned. The fourth center has a good deal to do with the condition before esotropia occurs.

When, in esophoria, the fusion faculty gives up its control over the right and left fourth basal centers, at that moment internal squint occurs, but so long as it has full power over these centers there can be no esotropia. Whenever these centers at the base of the brain have been overworked, then the fusion power of the mind gives way and internal squint occurs. Referring to one of the causative agents mentioned in Dr. Black's paper, as leading up to internal squint, I would say that center 10 in the cortex controls the focusing muscles of the eyes. The convergent center is the one marked 3, and it is connected by means of nerve fibers with both the internal

recti muscles. When it sends out its impulses the resultant action is on the part of the interni only. Cortical center 10, which gives power to the two ciliary muscles, is so related to cortical center 3 that when one is in over-action the other must also be in a state of over-excitation. This explains to my mind why it is that hyperopia is one of the causes of internal squint. In hyperopia the images would be bad if the focusing muscles were not kept in a state of action. But, as sure as center 10 is excited, so is center 3 reflexly excited. Hence it is that when you have hyperopia there is pseudo-esophoria. There is always esophoria whenever there is hyperopia; it may not show itself as esophoria, but it is there. How is it, then, that in correcting the error of hyperopia we can cure squint in young children? Simply this: when the proper lenses have been given, center 10 becomes as quiet as can be so far as distant vision is concerned, and from this time on it has only to do the normal work required of emmetropic eyes. Now, whenever over-action on the part of center 10 is eliminated so is over-excitation of center 3 eliminated, and thus the pseudo-esophoria is cured. But, pseudo-esophoria is not the only cause of squint. The esophoria itself may not have been able to produce squint, but the pseudo-esophoria grafted on it gives the combined power necessary to bring about that condition. If you eliminate the pseudo-esophoria you bring the two externi muscles under control of the right and left fourth basal centers, and esotropia is no more.

I endorse all of the paper, except that wherein the author speaks of a fusion center. I say there is a fusion faculty and that it presides over twelve fusion centers at the base of the brain, and two fusion centers in the cortex.

Dr. Black's improvement of the Worth amblyoscope makes it an ideal instrument.

Dr. Casey A. Wood, Chicago—In my investigations of the subject I agree with Dr. Savage. Apart from the considerations presented by Spencer and others in the study of the psychology of the matter I think binocular single vision is a thing that every child learns for himself. He does not have it when he is born, but acquires it. It is an effort of the intellectual faculties. He has to reason out the matter. In the first months of infantile life he makes efforts of the nature of which he is probably dimly conscious. Use is made of the radiations from the calcarine fissure which extend to the neurons in the upper cerebrum. After awhile he acquires the faculty of fusion and binocular single vision by means of the basal centers is possible.

I think a matter of great importance is the use of the Worth instrument. I think it is by all odds the best instrument we have for the exercise of binocular fixation in children, and I am sure you will agree with me that the instrument devised by Dr. Black furnishes the best means we have for that end. I have used the original Worth instrument since it was first accessible. The thing of principal importance in the Black modification is the vertical displacement of the two tubes to allow of exercise in the presence of hypertropias and cyclotropias, which are not properly provided for in the original instrument.

Speaking of Dr. Hale's paper, I must confess that the great array of cards for the stereoscope demands more patience than I possess. I am reduced to practically three pictures, which the child can not fail to recognize, and these I have so far found sufficient for all the exercise required. He will, for example, always recognize the picture of a bird with one eye and a cage with the other, and this particular card I almost always use. Indeed, I do not believe children are esepcially amused with a great variety of cards; their interest may be sustained with the same old "bird and cage." Let me suggest that an assistant watch the child all the time; few young children can be trusted to use with profit and alone any instrument of this sort. The exercises should be carried out at least three times a week in the office and the improvement noted. At home it is desirable to have a good stereoscope that will enable the child to be exercised three or four times a day under the care of the nurse or mother. In my experience the best stereopticon card is a very simple one. I use two figures made like this (illustrating on board) a square and a sphere.

Finally, as Worth points out, the fusion faculty can not usually be developed in children over 6 years of age. We should, then, begin our lessons as early as possible. In most cases the evolutionary course pursued by the squinting child, as shown by the amblyoscope and stereoscope, is, first, simultaneous (double) vision; second, binocular vision; third, binocular-single, or stereoscopic vision. Even when the eyes appear straight the squinter may never pass the first stage of vision.

Dr. Edward Jackson, Denver—One measure that has not been mentioned is the use of the fusion tubes suggested by Priestley Smith. The tubes have each at the further end, away

from the eye, simply a dot and a line, and these being fused give two dots and one line. It is even possible to work on cyclophoria by simply twisting the tubes. I find that the child will keep this up as long as any exercise that I have ever tried; certainly longer than any of the pictures. The light can be regulated for the better eye by pasting a little piece of paper over the slit in the tube. They give the very best binocular exercise: to recognize something with both eyes at the same time and to get primary fusion.

DR. M. D. STEVENSON, Akron, Ohio—I have been using the Worth amblyoscope for two years, and find it of real service in the treatment of squint when used sufficiently early, properly and persistently. The instrument as modified by Dr. Black, if it can be made sufficiently firm, should be especially serviceable where hypertropia is also present.

I think the term fusion faculty is preferable to that of fusion center, and believe it to be the principal factor in the production of binocular vision, although I also believe it is presided over by another faculty, which I prefer to name the conscious faculty of vision, rather than the volitional center.

Usually the first thing in the treatment of these cases is to establish conscious vision if possible in each eye, that is, we try to teach the child to see with each eye at the same time, or, in other words, try to produce diplopia, e. g., the bird within the cage, and when we have succeeded in doing this we have progressed a long way toward a cure. This may be spoken of as the establishment of conscious vision in each eye—the training of the conscious faculty of vision—and until this can be accomplished in a case there can be no training of a fusion faculty or center, because there would be as yet nothing to fuse, their being but one recognized image. Two images must be seen—the conscious faculty of vision in each eye must be trained—before there can be any fusion. If the vision of one eye is unconscious, that is, if it has not risen into consciousness, there can be no tendency to combine the unconscious vision of that eye with the conscious vision of the other. Before fusion can take place the vision in both eyes must be conscious at the same time. Quite a large number of people do not have conscious vision in both eyes at the same time; in them it takes training to produce either diplopia or double combined (binocular) vision.

DR. NELSON M. BLACK, Milwaukee—A mistake was probably made in attempting to go into the etiology of strabismus in this paper, but it was thought necessary in order to have some reason for carrying out the line of treatment mentioned. However, the name "fusion faculty," given by Dr. Savage, is as acceptable as "fusion center"; whatever it may be called neither adds to nor detracts from the universal good results obtained in treating strabismus by this method. I thank Dr. Savage for the easy manner in which he has let me down.

DR. ALBERT B. HALE, Chicago—I want to call Dr. Savage's attention to the fact that the fusion faculty can often be controlled by the will so that they are not antagonistic or complementary, but one may at times be supportive of the other.

I did not mean these cards to be competitive with the Worth instrument. They are only a set of cards that the patient can take home for daily exercise, and that is what we want. I have had good results from simple stereoscopic pictures.

A DEVIATION FROM THE USUAL METHODS OF CLOSING ABDOMINAL WOUNDS, INCLUDING HERNIA.*

O. O. WITHERBEE, M.D.
Surgeon to Los Angeles County Hospital.
LOS ANGELES, CAL.

A troublesome experience with buried sutures has defeated the best efforts of many excellent surgeons in their endeavor to separately approximate the different layers in closing abdominal wounds.

* Demonstrated before the Southern California Medical Society, and read before the Los Angeles County Medical Society.

With a desire to overcome this difficulty, and yet to accomplish all that may be done with buried sutures, I began about two years ago the exclusive use of silkworm gut in closing, not alone abdominal wounds, but in suturing all incisions I have had occasion to make in doing a general line of surgery.

In closing an abdominal wound in the medium line it is my habit to first approximate the peritoneum with a silkworm gut introduced in the same manner as a subcuticular suture, and then to bring both ends through the integument near the extremities of the incision. This permits of its ready removal any time from the third to the sixth day, according to the pleasure of the operator.

The abdominal fascia is now brought into apposition by ordinary figure-of-eight sutures, except that the ends

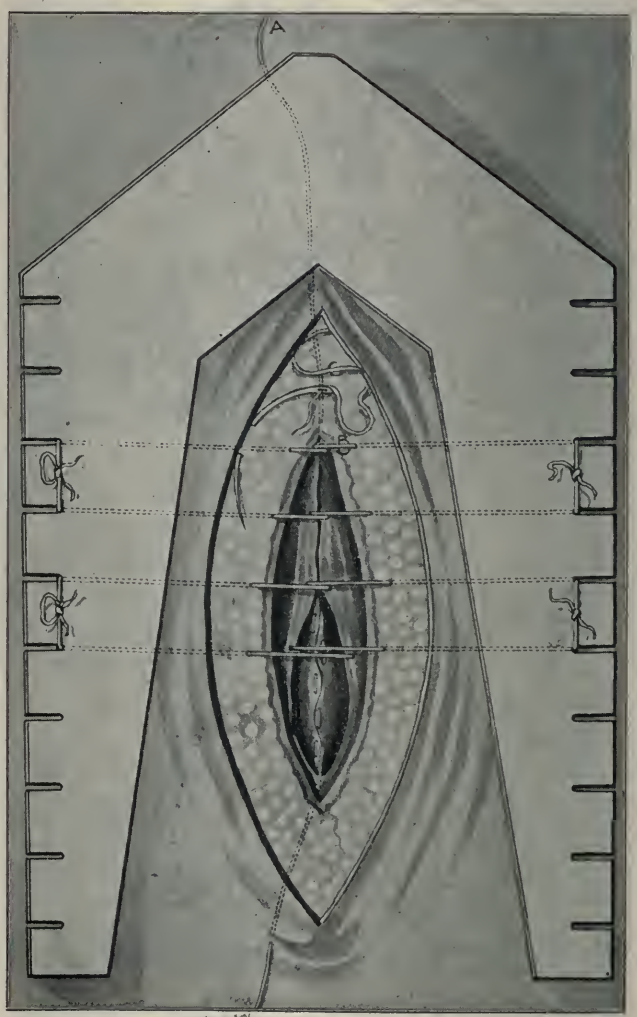


Fig. 1.—The U-shaped aluminum plate employed in closing abdominal wounds. A. The peritoneal suture, which should emerge near extremity of wound instead of above the plate. B. The figure-of-eight suture, which is supported by the plate. C. The subcuticular suture.

instead of being brought out near the margins of the wound, are carried by long curved Hagedorn needles through the adipose tissue to emerge on a line parallel with the abdominal incision and from one and one-half to two inches on either side of it.

These ends are passed through notches in the lateral bars of a U-shaped or rectangular framework, made from aluminum or hard rubber, the outer dimensions of which measure from three to four inches in width, and from four to six inches in length. The sutures are then

tied in pairs on each side respectively, with just sufficient tension to perfectly approximate the fascia. On one side the ends should be tied in a bowknot, that the tension may be altered if necessary.

The skin incision is next closed by a subcuticular suture, and when completed strips of sterile gauze are drawn beneath the plate and a moist bichlorid dressing placed over all. The same tactics are made use of in the treatment of hernia, except that the peritoneal suture is quilted back and forth through the neck of the sack, and its ends carried well above the internal ring, where they are brought through the tissues and secured to the upper part of the framework, said suture to be removed at the end of one week.

In approximating the conjoined tendon with Poupart's ligament, the tension should be exerted on a plane to correspond with the resistance to be overcome.

The above-named structures do not normally lie in apposition, but are often widely separated, hence the difficulty in effecting and maintaining their approximation until union is complete. The ordinary figure-of-eight sutures brought out near the margins of the wound will utterly fail in a large percentage of cases, especially

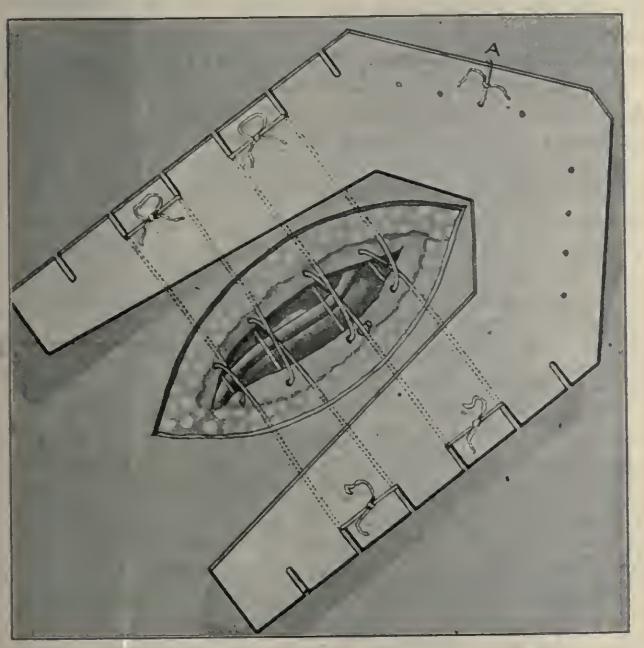

Fig. 2.—Represents the U-shaped aluminum plate employed in approximating the conjoined tendon with Poupart's ligament. A. The peritoneal suture, which fixes neck of sac above internal ring.

if the skin alone is relied on to withstand the resistance.

By bringing the sutures out at a remote distance from the incision and securing them to the framework above the skin, we accomplish all that can be done with a buried suture, while the tissues are subjected to much less abuse than when a knot is employed at point of approximation, thereby creating a fixed, unyielding band, which materially interferes with the circulation, and does certainly lessen the strength of union between those ligaments. Another advantage of this method in the treatment of hernia lies particularly in the fact that the tension of the sutures can be altered at any time the swelling or congestion of the parts may demand it.

In abdominal work the comfort secured to the patient by relieving the skin of that pressure necessary to maintain approximation of the deeper structures is frequently a factor of no small importance. Little does the surgeon think when placing his sutures that their position may have much to do with the welfare, and even the recovery, of the patient. Since endeavoring to eliminate that pressure occasioned by the closing sutures, I have noticed that my patients exhibit less evidence of shock, and that it is not an uncommon thing for one to sleep almost the entire night following an abdominal section.

Most of the creatures subjected to this torment are women, who, it is said, were born to suffer, and therefore uncomplainingly endure for long hours a slow torture which they fancy belongs to the operation, and so must be borne.

It is true they do not speak especially of the stitches, for the reason that they can not differentiate varieties of pain coming from the same region, but appreciate it all as a sum total, and bear it, as there is nothing else to do.

In abdominal cases the sutures may be removed from the eighth to the tenth day, but in hernia cases, to insure

Fig. 3.—Represents the use of separate plates for increasing the pressure area in plastic work.

certainty of union, the sutures should not be removed before the twelfth or fourteenth day.

In plastic work when it becomes necessary to draw the skin over denuded areas of considerable size, the same manner of closing may be employed without fear of sloughing as a result of pressure from the sutures. Here we simply invert the small loop of the figure-eight, in which case it acts as an interrupted coaptation stitch, minus the knot, and may or may not appear above the surface of the skin. In order that it may also serve as a retention suture at point of emergence beneath the plate only lateral perforated bars should in this instance be employed.

Again, when closing short incisions where there is a scant amount of adipose tissue the plates may occupy a position near the margins of the incision, in which case the transverse support may be omitted.

In abdominal work before making the initial incision, the lateral boundaries of the framework should be outlined on the integument by a delicate scratch made with the point of a scalpel.

In closing, the sutures emerge at this line (which has now become visible from congestion) and when tied on both sides produce sufficient fullness of the intervening integument to prevent tension at the line of incision. No adhesive strips are necessary for abdominal support, and the binder may be applied only moderately snug.

The cosmetic effect is all that could be desired, as the cicatrix remaining after removal of the subcuticular suture is seldom more than a delicate white line.

The stitch holes beneath the plates close up and disappear.

The time consumed in adjusting the plates does not prolong the operation, and with a little practice is quite as convenient as the old way.

610 Frost Building.

SCARLET FEVER.*

WILLIAM L. BAUM, M.D.

Professor of Skin and Venereal Diseases, Post-Graduate Medical School of Chicago; Attending Physician on Contagious and Infectious Diseases, Cook County Hospital; Dermatologist, the Chicago and German Hospitals.

CHICAGO.

During the years 1896 to 1903 the following cases of scarlet fever were under my observation at the Cook County Hospital:

Number of cases, 628; males, 307; females, 321; deaths, 44.

Complications.—Suppurative otitis, 11; nephritis, 47; pneumonia, 19; arthritis, 2.

Mixed Infections.—Number of cases, 142; deaths, 17; diphtheria, 96; measles, 29; diphtheria and measles, 1; varicella, 13; parotitis, 3.

It will be seen from the above table that the mortality was a little over 7.07 per cent. of all the cases treated. In the mixed infections the mortality was 11.9 per cent. It will be noted that among the complications, suppurative otitis media occurred eleven times, or in 1.7+ per cent. of all cases. In about 35 per cent. of the cases there was pain in the ear. The mild or catarrhal form of otitis media, according to Bader and Guinon,[1] is very common, occurring in 33 per cent. of the cases.

Holt[2] has found it in 75 per cent. of those cases accompanied with severe throat symptoms.

Nephritis, in which there were present albumin, casts and blood cells, occurred in 47 cases, or in 7.6+ per. cent. of all cases. Albumin was present in over 37 per cent. of the cases during the early stages of the disease.

In three cases there was present at the beginning, or on the second day of the eruption, a severe septic nephritis, with much albumin and many casts. These cases were all fatal.

Acute lobar pneumonia was present in 19 cases, mostly involving the upper lobes. Henoch[3] states: "The mucous membrane of the bronchi and the parenchyma of the lungs are excited by inflammatory influences far more frequently than we usually suppose. Not only catarrh, but more or less extensive bronchopneumonia occurs in the first and second weeks of the disease. These conditions are frequently overlooked, however, because a whole series of synchronous severe typhoidal symptoms disguise them and divert the attention of the physician." We found bronchitis and bronchopneumonia in nearly all severe cases.

Severe arthritis was present in two cases; in one of these cases, a girl 10 years of age, the swelling of both elbow and wrist joints appeared on the tenth day of the disease. It was ushered in by a chill, rise of temperature to 104 degrees and great tenderness in the joints. The symptoms increased in severity up to the twenty-eighth day of the disease; the joints became soft and fluctuating, the aspirated fluid was filled with streptococci and the child finally died of a general sepsis. There was also present nephritis.

In 21 other cases there was slight swelling of the joints, but unaccompanied by any other severe symptoms.

Among the mixed infections, diphtheria was the most common. Cultures are made from the throats of all patients admitted to the contagious and infectious ward of the Cook County Hospital. In the 628 cases of scarlet fever, the Klebs-Löffler bacillus was found 96 times, or in 15.2 per cent. of all cases. It is well, however, to state that in many cases it appeared as a purely secondary infection during the period of early convalescence and after exposure. Jürgensen[4] answers some points in regard to diphtheria complicating scarlet fever as follows: (1) Is any one able, by simply inspecting the genuine diphtheritic membrane, to differentiate it from the membranes that occur in a scarlatina that is not complicated by diphtheria? In many cases, yes. In diphtheria these are firm, compact membranes of a grayish yellow color, that can be separated in their entirety. In scarlatina the membranes are softer, looser, separable only in portions and of a more brownish color. To this I can not agree, for in many of the cases of the latter type the Klebs-Löffler bacillus was found, and not only this, but from these cases others were infected with diphtheria. (2) A deep destruction of the tissues in the vicinity of the parts primarily involved is more rare in diphtheria than in scarlatina. (3) Obstruction of the larynx by a membrane formation is a comparatively rare occurrence in scarlatina, and still more rare is a croupous exudate on the mucous membranes, extending deep down into the air passages. (4) I do not wish to lay too much stress on the fact that in the involvement of the larynx by a diphtheritic inflammation from the pharynx accompanying scarlatina, the clinical symptoms have a characteristic type. (5) The paralysis following genuine diphtheria is absent in the pharyngeal diphtheritis accompanying scarlatina. (6) As to the time required by the course of the disease, Henoch declares, in regard to the condition that he calls the necrotic inflammation typical of scarlatina, that it appears, as a rule, on the third or fourth day after the beginning of the disease; this holds good only for the cases that are moderately severe. In severe cases it may be present even in the course of the first twenty-four hours.

Corlett[5] states that among contagious and eruptive fevers none presents so many varied types as scarlet fever, ranging, as it does, from the mildest form, scar-

latina simplex, or benigna, to the most malignant type, scarlatina maligna, called by the French foudroyante. Between these two extremes we find an almost endless variation from the normal, one shading gradually into the other; so that any sharp differentiation into groups is quite impossible. It is this constant variation in type which renders the differential diagnosis of scarlet fever from other disease processes so difficult.

In differential diagnosis, drug eruptions, as caused by belladonna, quinin, copaiba, chloral, opium and the coal-tar derivatives, must be taken into consideration, for not only are the conditions for which they are prescribed accompanied by fever, but the drug eruptions frequently start on the face and locations characteristic also of the scarlet fever eruption. Toxic erythemata occur in the course of septic infections, which are frequently mistaken for scarlet fever eruptions. In both of the above conditions the enlargements of the glands in scarlet fever, as shown by Schamberg, are of diagnostic value. Cases of rubella, or German measles, are frequently mistaken for mild scarlet fever, and it is with great difficulty that the diagnosis is arrived at. In the scarlet fever the rash is made up of minute, brightly injected puncta, slightly elevated and closely studded together, forming a uniform or finely mottled surface, while the rash in rubella is always measly, and never becomes confluent.[5]

Other cases which had been sent into the hospital as scarlet fever proved to be erysipelas, cerebrospinal meningitis, measles, tonsillitis with erythema, influenza and one case of septic typhoid fever.

It is strange that where so many children who had recently undergone surgical operations were exposed to the infection that only in two instances did scarlet fever develop among them. Hoffa[6] believed that scarlatina can originate from wounds, and quotes Von Leube, who infected himself during an autopsy on the cadaver of a case that had died of an unusually severe attack of scarlet fever.

ETIOLOGY.

Since the report of Klein,[7] in which he was convinced that the Marylebone epidemic of scarlet fever in London could be traced to the milk supply, and found the streptococcus taken from the vesicles on the udders of cows, which he believed were suffering from true bovine scarlatina, there have been many others, notably Fiessinger,[8] who believe that they have discovered the true etiologic factor. Class[9] describes a diplococcus. His organism is a non-capsulated diplococcus appearing occasionally, though rarely, in streptococcic form. It is polymorphous in character, attaining not uncommonly, under certain conditions, an unusual size. It is said to be constantly present in the pharynx in the scarlatinal angina. Baginsky and Sommerfeld[10] have described a streptodiplococcus very similar to the one described by Class. We have endeavored to follow out this work, especially on the lines laid down by Class, but have found so many similar organisms in the throats of patients, suffering from the infectious diseases, that the results are inconclusive.

Weaver[11] made many cultures from the throats of scarlet fever patients and reaches the following conclusions:

1. The bacteria obtained in cultures from the skin, epidermic scabs, and the surface of the tonsil, are the same as those found in the same locations in health, and no one of them is constantly present, except the streptococcus in the throat.

2. Because of the numerous cocci which grow in such cultures and which appear in groups of two and four, or bunches of the same, under the microscope, it is impossible to identify them except by a complete study in pure cultures.

3. Cultures made by inexperienced persons, or by those who do not fully appreciate the importance of avoiding the tongue, are especially apt to contain large diplococci or sarcinæ.

4. The streptococcus is present on the tonsil of scarlatinal patients in enormous numbers in almost all patients.

Hektoen,[12] in a series of bacteriologic examinations of the blood, during life, in scarlet fever, with special reference to streptococcemia, comes to the following conclusions:

1. That streptococci may be found in the blood of cases of scarlet fever that run a short, mild and uncomplicated clinical course.

2. That streptococci occur with relatively greater frequency in the more severe and protracted cases of scarlet fever in which there also may develop local complications and clinical signs of general infection, such as joint inflammation, but even in the grave cases of this kind spontaneous recovery may take place, and, finally,

3. That streptococcemia may not be demonstrable in fatal cases of scarlet fever.

The theory that scarlet fever is a streptococcus disease does not seem to receive any direct support from this work.

After a study of the literature bearing on the subject of the bacteriology of scarlet fever and an endeavor to verify the works of the investigators, one is forced to the conclusion that it has not yet been shown that any one of these organisms is the true etiologic factor in scarlet fever.

DISCUSSION.

Dr. Jay F. Schamberg, Philadelphia—I regret that Dr. Baum was not able to read that part of his paper on the clinical description of scarlet fever. The differential diagnoses between scarlatina and certain scarlatiniform erythemata is frequently involved in great difficulty. In some cases it is utterly impossible to be sure whether one is dealing with a scarlatinoid rash or the true eruption of scarlet fever. The exanthem of scarlet fever may be regarded as a toxic erythema or dermatitis; there are other substances besides the scarlatinal poison which are capable of producing a similar eruption. Quinin, belladonna, antipyrin, opium, mercury and other drugs may produce rashes which may closely simulate the scarlet fever exanthem. Erythemata occurring in certain infectious diseases and septic states may be quite indistinguishable from that observed in scarlet fever.

Differentiation would be easy if all cases of scarlatina were frank and well pronounced. It is a facile matter to recognize as scarlet fever an attack characterized by sudden rise of temperature to 104 F., vomiting, inflamed throat, a diffuse punctated rash, strawberry tongue, general glandular enlargement, with the subsequent development of otitis media, nephritis, rheumatism or albuminuria. It is an easy matter to set down on paper a differentiation between typical examples of scarlet fever and scarlatiniform erythema, but such information often fails one at the bedside.

There are mild cases of scarlet fever in which the fever is insignificant, and the throat symptoms no more pronounced.

Indeed, in atypical cases the disease may exist without fever, without angina, or even without a rash.

The history of the case is often of importance in clearing up the diagnosis. If the attack can be shown to have resulted from an antecedent case, or if it give rise to a subsequent infection, the diagnosis is at once simplified. The appearance of the tongue carries considerable diagnostic weight—not so much the coated tongue with red papillæ peeping through, but the red, papillated tongue which is seen about the third day of the disease—the so-called strawberry tongue. It is uncommon to find such an appearance of the tongue in scarlatiniform erythema.

Too much importance has been attached to the occurrence of desquamation. Scaling after a scarlatinoid rash has been regarded as confirmatory evidence of the scarlatinal nature of the disease. Dermatologists recognize the fact that desquamation will follow any scarlatiniform erythema which has been characterized by sufficient inflammatory change in the skin. Indeed, these erythemata often scale much more profusely than the rash of scarlet fever. More important than the mere existence of scarlatinal scaling is its persistence. It is not rare to see a comparatively mild attack of scarlet fever in which the desquamation may persist for five, six or seven weeks. A point of diagnostic value in the desquamation of scarlet fever is a tendency of the epidermis to split just beneath the free border of the nail (*Subungual cleavage*), the epidermis then peeling off down the finger and exposing the pinkish, tender skin beneath. This usually occurs from about the tenth to the fourteenth day.

Scarlatiniform erythema may usually be distinguished by a lesser grade of constitutional disturbance, the eruption being disproportionately pronounced as compared with the fever and prostration. The throat may be reddened, but the tonsils are not swollen and covered with exudate. The red papillated tongue is usually absent. Enlargement of the maxillary gland is not present. Furthermore, there is often a history of recurrent attacks of these erythemata. Many reported cases of repeated attacks of scarlet fever have doubtless been instances of erythema scarlatiniforme recurrens.

There is no acute infectious disease which is more often attended with diagnostic difficulty than scarlet fever. Poorly-marked cases are frequently overlooked, and other counterfeiting rashes are often diagnosed as scarlet fever.

DR. A. W. BRAYTON, Indianapolis—Did Dr. Baum say anything about the scarlet fever they had along the lake shore 35 or 40 miles north of Chicago during the last winter in Evanston and Lake Forest? I had some patients from Lake Forest who said the place was quarantined. They stated that there were no deaths and that there was a good deal of difference of opinion as to whether it was scarlet fever. The disease in Indianapolis has been of a mild type for the last ten years. Very few deaths have occurred, not more, in proportion, than from measles.

DR. HENRY G. ANTHONY, Chicago—In answer to Dr. Brayton I wish to state that I had an opportunity of seeing some of these cases, and there is no question that they were typical scarlet fever, and they were not all mild.

DR. LUDWIG WEISS, New York—I would ask Dr. Baum whether in those cases which proved to be clinically light there has been noticed a rash in and below the inguinal folds, below Poupart's ligament, and having a burnished aspect. I have seen this symptom several times, and my attention was drawn to it, especially in a case where after an operation for adenoids the child developed a rash which looked like scarlet fever, but where a diagnosis could not be made at once. Of course it might have been caused by traumatism, as eruptions sometimes occur after operations, but it developed later that it was true scarlet fever. If those who see so many cases would notice this symptom, it would help a great deal toward making an early diagnosis.

DR. J. B. KESSLER, Iowa City, Iowa—I am sorry the author did not go into the clinical aspect more particularly, because it is important; at times it is difficult to make a diagnosis of scarlet fever. I know a medical man who graduated and located in Dubuque, Iowa, years ago, who showed an eruption to some of his colleagues. They were in doubt as to the trouble, but agreed among themselves that as he was a young man they would shut him up anyway, so they told him he had scarlet fever. I have been acquainted with him for seven years and have seen him in his operating room with this eruption, which shows a mild grade of erythema scarlatiniform. The throat will be slightly reddened, and there will be slight malaise for three or four days before this comes out and while the eruption remains. This is followed by mild desquamation. This has been repeated for twelve years.

In our city scarlet fever is pretty well "vaccinated" out. I do not remember of a death in the city for twenty years, but strange as it may seem, in the adjoining towns I have seen severe cases. Last summer I attended a severe case of scarlet fever in a little girl where the glands of the neck became involved and suppurated.

In regard to the spreading of scarlet fever, I think that is largely due to neglect in not having the cases properly inspected before quarantine has been removed. I remember some years ago there was a question of diagnosis in a case of scarlet fever. The mother said that her son had had scarlet fever, and our health officer was in doubt about the case. I told him I thought he had scarlet fever, but as the health officer had let him out I would like to have him drop in occasionally so that I could watch the desquamation. I watched the desquamation for thirty days, and at the expiration of that period, to get rid of it, he sandpapered the soles of his feet. This was indicative to me that there is a chance to spread scarlet fever beyond the ordinary quarantine of thirty days.

DR. WILLIAM L. BAUM, Chicago—I regret that it was not possible to present this paper in full, and I thank Dr. Schamberg for calling attention to the clinical side of the case. Experience demonstrates that the diagnosis is often made with considerable difficulty. It has occurred in the hospital that the typical symptoms seemed to be absent, and patients have been transferred on account of the early disappearance of symptoms.

Dr. Brayton's question in regard to the Evanston epidemic was answered by Dr. Anthony. A number of severe cases coming from that district were transferred to our service, but I do not remember that there was a single death. However, I am glad the gentleman called attention to the mortality. It is rather interesting that in these hospital cases, which are largely drawn from the other wards of the hospital, the children's ward and from districts where you would expect illy-nourished children, the mortality is less than 7.7 per cent. Included in these mortality statistics are those brought to the hospital in a moribund condition, and who died within six hours of their admission.

Dr. Weiss calls attention to an eruption in the inguinal folds below Poupart's ligament. This I have not seen. It is a symptom to which I am glad to have my attention called, as I have not found it in any of our cases. We see many cases of scarlatiniform erythemas, and I believe most of the surgical scarlet fever is of this type. It is an interesting fact that in the children's surgical ward during a period of nine years, where at times as many as thirty or forty are exposed, only two cases of scarlet fever have developed.

Regarding the period of isolation, we isolate a patient at least forty days whenever possible and find that that period is sometimes not long enough. I am convinced that the statement made by many clinicians that the incubation period is not infectious is a mistake. We have had a number of cases where the exposure could only have occurred in the pre-eruptive stage.

Under Water Five Minutes.—To settle a dispute, George Kistler, swimming instructor at the University of Pennsylvania, recently remained under water five minutes and five seconds. It is stated that an examination by a physician following the feat showed no departure from the normal except some acceleration of the heart's action.—*Medical News.*

Special Article.

THE PURIFICATION OF WATER SUPPLIES BY SLOW SAND FILTRATION.

(Continued from page 853.)

II.

WATER FILTRATION IN THE UNITED STATES.

The first sand filter constructed in the United States was the one built in 1872 under the direction of Mr. J. P. Kirkwood at Poughkeepsie, N. Y. A similar filter was installed by the same engineer at Hudson, N. Y., in 1874. Both these plants are still in operation. Although a beginning in water purification in this country was made at this early date, a more decisive step was taken by the construction of a sand filter at Lawrence, Mass., in 1893. The establishment of this filter may be said to mark the opening of the modern era in water purification in America. One of the leading American authorities on water supply has said:

> The Lawrence filter was in a large sense the beginning of water purification in America. This is particularly true when the matter is considered from a hygienic standpoint. A few filter plants had been built in America before the Lawrence filter, but these earlier plants had been directed largely or principally toward improving the physical character of the water. At Lawrence, for the first time, a filter was constructed with the deliberate purpose of reducing the death rate. The success that was achieved in accomplishing this result attracted the attention of the whole country and was of the greatest service in directing attention and energy to a most important subject, which up to that time had not received the attention which it deserved.

Another distinguished engineer has said:

> It is difficult to estimate readily how great has been the benefit which this filter has produced outside of the city of Lawrence. It has proved a stimulus and an example for many later developments in this field, and it has served as a basis of reference for engineers and sanitarians, not only in this country, but also in Europe. No matter how many filters may be built in years to come which are larger in capacity or more efficient or more economical in operation, it is very doubtful if any will succeed in displacing the Lawrence filter from the classical position which it now securely holds as marking the beginning of a new epoch, and, in fact, the first epoch of important practical accomplishments in this country in water purification.

A. THE LAWRENCE FILTER.

The city of Lawrence is situated in the northeastern part of the state of Massachusetts, near the New Hampshire boundary line. According to the U. S. census of 1900, its population was 62,559. The city lies on the Merrimac river, a stream which affords water power for various manufacturing interests, and from which since 1876 the public water supply has been derived. The present population on the watershed of the Merrimac above Lawrence is estimated as about 480,000, nearly 318,000 of which is urban population and therefore constitutes an important source of pollution. It was calculated that in 1900 the proportion of sewage flowing in the stream past Lawrence amounted to one gallon in every 200 at periods of average flow, and one gallon in every forty in the driest periods. The most dangerous element of pollution is the crude sewage discharged from the city of Lowell, eight miles above Lawrence. Like Lawrence, the city of Lowell has until recent years obtained its water supply from the Merrimac river and has in consequence suffered severely from typhoid fever, and the fact has been noted on several occasions that an increase of typhoid fever in Lowell has been followed in due course by an increase in the disease at Lawrence. Prior to the introduction of a pure water supply the typhoid fever death rate in both Lowell and Lawrence had for years been excessive, and averaged as high as from three to four times the typhoid fever rate in the state at large. It was primarily to remedy this serious condition that the construction of the Lawrence filter was undertaken in the fall of 1892 at the instigation of Mr. Mills, an eminent engineer and public-spirited citizen of Lawrence, and pushed to completion by September 20 of the following year.

The filter is located a short distance above the city of Lawrence on the north bank of the Merrimac river. Its total available filtering surface is about two and one-third acres. Until recently the filter bed has been maintained as a single unit, and, as will be seen, the lack of subdivision of the filtering area has greatly embarrassed the general operation of the plant.

The quality of the Merrimac river water does not present any special difficulties. The water does not usually contain a large amount of suspended matter, and the silt carried at times of flood is relatively coarse and is of a kind that settles out rapidly. The number of bacteria in the river water is not as high as in many other polluted river waters in the United States, ranging, as a rule, about 5,000 to 10,000.

During the ten years that the Lawrence filter has been in operation, a number of instructive incidents have occurred in connection with it which have emphasized certain of the fundamental tenets of sand filtration and have developed new points for future warning and guidance. At the time the filter was originally built it was intended that it should be operated intermittently, it being at that time supposed by Mr. Mills that purification would be more effective if the air were admitted to the sand at frequent intervals, as in fact is known to be the case in sand filtration of sewage. Certain exigencies of operation, however, due primarily to the amount of water demanded by the city, soon led to the abandonment of the system of intermittent operation and the maintenance of practically continuous filtration. Entirely favorable results have been secured by the continuous method, and the superior yield of water when the filter is operated continuously renders improbable a return to the original method.

Many of the most harassing circumstances in the operation of the Lawrence filter have been due to the lack of a cover. During the winter months the proper scraping of the filter surface has been greatly hampered by the frequently recurring necessity for removing a layer of snow and ice. The diminution in the yield of the filter, the marked interference with the bacterial efficiency and the exorbitant expense of dealing properly with the frozen surface are factors that have seriously impaired the efficiency of operation. The cost of removing the ice has sometimes amounted in a single winter to over $3,000, or more than one-third of the total cost of maintenance. Those in charge of the Lawrence plant have often urged on the city authorities the economy of covering the filter, but for reasons easily understood by those conversant with American municipal conditions, an annual outlay for labor is more attractive to the average city council than an expenditure for interest charges.

The original cost of the Lawrence filter was surprisingly low, amounting to only about $66,000, but the enforced economy practiced in certain directions at the outset has not been justified by several occurrences in the history of the filter. Perhaps the most notable in-

stance of this sort is the trouble that has been occasioned by the lack of a watertight bottom to the filter. The absence of this protection has at times allowed ground water to enter, carrying with it a certain amount of iron in solution. The presence of iron is known to favor the growth of a microscopic fungus, *Crenothrix* by name, an organism which by its accumulation in pipes and underdrains, has given rise to much trouble in the waterworks of Berlin, Rotterdam and other places. At Lawrence the underdrains of the filter became gradually clogged with a heavy filamentous growth of *Crenothrix*, and finally the passage of water was impeded to such an extent that it became necessary to reconstruct the drainage system. The processes of repair inevitably led to considerable disturbance of the filtering surface, and was promptly followed by a decrease in the bacterial efficiency of the filter, and a little later by an increased number of cases of and deaths from typhoid fever. Many other similar experiences in connection with the operation of European filter works have shown that a very slight disturbance in the operation of the filter may affect profoundly the health of the community supplied with the water. The municipal parsimony at Lawrence which failed to provide watertight filter basins must be held directly responsible for the loss of human life.[3]

Mention has already been made of the great difficulty experienced in cleaning the Lawrence filter, due to the construction of the filter plant as a single bed instead of in sections. The latter arrangement would have greatly facilitated operation and lessened the cost of maintenance by making it possible to clean properly one section of the filter while the supply was being kept up by the remainder. A belated subdivision of the filtering area was carried out in 1901, when two transverse division walls were constructed dividing the filter bed into three sections of about equal area.

BACTERIAL EFFICIENCY.

From the outset the effluent of the Lawrence filter has been regularly examined with a view to determining the bacterial efficiency of operation. The following table shows the reduction in the number of bacteria attained by passing the river water through the filter.

TABLE 1.

AVERAGE NUMBER OF BACTERIA PER CUBIC CENTIMETER.

Year.	In Water Applied to Filter.	In Water Drawn at Tap at City Hall.
1894	10,800	110
1895	11,100	80
1896	7,600	85
1897	10,900	84
1898	4,400	66
1899	5,800	42
1900	8,970	49
1901	3,017	26

Examination of the detailed figures[4] brings to light the interesting fact that in the latter part of 1898 and the early part of 1899, when the already mentioned repairs of the underdrains were being undertaken, the number of bacteria in the tap water was from four to five times as great as during the rest of the year. This confirms the opinion already expressed concerning the connection between the disturbance of the filter and the unusual number of cases of typhoid fever that appeared in the city early in 1899.

A very interesting feature in the methods of water examination employed at Lawrence since the latter part of 1898 has been the application of the test for the presence of *B. coli communis*. The presence of organisms of this class, as is well known, is a more delicate and satisfactory indication of the existence of sewage pollution than the ordinary numerical determination of all colonies developing on a gelatin plate, and unquestionably affords a more exact criterion of the quality of the water. The management of the Lawrence filter seems to have been the first to apply this test to filter effluents. The method has been found so illuminating that it is doubtless destined to a wider extension as its value becomes more generally known. The disturbance in the working of the filter in the latter part of 1898 is betrayed in a very striking manner by the increase in number of colon bacilli appearing in the effluent water.

The final and decisive test of the efficacy of any system of filtration must always remain the condition of the typhoid fever death rate of the community supplied with the water. The following table exhibits the application of this test to the Lawrence filter.

TABLE 2.

REPORTED CASES OF TYPHOID FEVER AND THE DEATHS RESULTING THEREFROM IN LAWRENCE BEFORE AND AFTER THE INTRODUCTION OF A FILTERED WATER SUPPLY.

Year.	No. of Cases per 10,000 Pop'n.	No. of Deaths per 10,000 Pop'n.	Typhoid Fever Death Rate for State of Mass.
Six Years Prior to Construction.			
1887	33	11.7	4.5
1888	50	11.6	4.5
1889	51	12.8	4.1

Several complicating factors must prevent the drawing of any sweeping conclusions from the figures in this table. One of these is the continued use of canal water for drinking in several of the Lawrence mills, a practice that persists in spite of continued and emphatic warnings. A study of the cases of typhoid fever occurring in the city from year to year has shown that a considerable proportion of cases and deaths have appeared among persons known to have partaken of the polluted canal water. It is said that in 1894 twelve deaths out of the twenty-four recorded for that year were among the drinkers of canal water, and in 1895 nine out of sixteen. Deducting known infections from this source would give a much more favorable aspect to the work of the filter.

On the other hand, as tending to diminish the credit to be assigned to the filter for the lowering of the typhoid death rate, it has been pointed out that since the installation of the filter the city of Lowell, previously the main source of pollution of the Lawrence water supply, has introduced a pure ground water. As a result of this improved supply typhoid fever has diminished very greatly in Lowell. The improvement in the condition at Lowell indicates that, even had a filter not been introduced at Lawrence, a decline in the typhoid fever death rate would have occurred as a result of a decreased prevalence of this disease in Lowell.

For these reasons the benefits accruing from the introduction of the Lawrence filter do not stand forth as clearly as they might have done under some other conditions. In view, however, of the figures in Table 2,

3. See increase in typhoid fever in 1899, Table 2.
4. Thirtieth and Thirty-first Reports of State Board of Health of Massachusetts, 1898 and 1899.

there is no escape from the conclusion that a remarkable decline in the typhoid fever death rate occurred immediately after the construction of the filter and has persisted up to the present time.

Recapitulating some of the lessons gained from the experiences at Lawrence,[5] these are:

1. The importance of proper construction at the outset as obviating the necessity for repairs, and the consequent serious disturbance of the filtering process.
2. The desirability of subdividing the filtering area in a small or moderate-sized filter plant.
3. The necessity for covering the filters in cold climates.
4. The value of the test for the presence of *B. coli communis* in filter effluents.

(To be continued.)

Clinical Report.

A CASE OF CONGENITAL SACRAL TUMOR—SPINA BIFIDA.

E. VIKO, M.D.
SALT LAKE CITY.

Reading the report of a case in THE JOURNAL, July 25, 1903, by Dr. R. Henderson, leads me to relate a unique case in my experience:

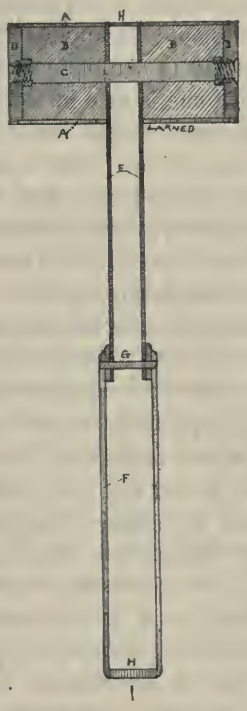
July 4, 1898, I attended Mrs. C., aged 25, in her second confinement. Labor progressed rapidly and normally until the head and body down to about the navel protruded from the vulva, when there was a sudden check to the expulsion of the hips and lower extremities. On pulling gently the hips appeared to be firmly held by some obstruction in the uterus. My first thought was that I had possibly to deal with twins. The uterus seemed to be unusually full. As part of the body of the baby was in the vagina and the hips and lower extremities in the uterus, it was difficult to explore the genital canal, but some kind of tumor could be distinctly felt projecting from the sacrum of the infant. On making strong traction the hips and lower extremities were suddenly delivered with a gush of a large amount of liquid. The body, which lived about fifteen minutes, weighed about fourteen pounds.

On examination, it was found that the entire coccyx and sacrum were undeveloped. The skin over the sacral region was elongated in the form of a sac, extending to the knees of the infant. The anal orifice was located about two inches below the perineum in front of the tumor. On the lower part (summit of tumor) coursed large veins, which had weakened the skin at this place, where under the strong traction the skin broke. The baby was otherwise well formed and fat.

Keith Building.

New Instrument.

A NEW SURGICAL MALLET.



E. R. LARNED, M.D.
CHICAGO.

This instrument is made entirely of metal, presenting on all sides perfectly smooth surfaces, making it as easy to sterilize as any other surgical instrument.

The principal part of the mallet, the head, is made as follows: Two steel faces (D) 1⅜ inches in diameter and 3/16 inch thick, are turned in a lathe, leaving the center 5/16 inch thick and ⅜ inch in diameter, as shown in the sketch, which is full size. The shell of the head (A) is of seamless brass tubing and fits into little recessions in the steel faces. A block of pure aluminum is turned to exactly fit the inside of the shell. This filling (B) has a hole drilled through the center ¼ inch in diameter, through which runs a steel pin (C), the ends of which have right and left threads, the steel faces being screwed on this pin, after which the protruding ends are riveted flush with the steel faces.

The handle is made of seamless brass tubing, soldered and then held together at G with a small steel pin, which is riveted. The portion of the handle marked E is fitted into the hole drilled through the head to exactly admit it, before the steel pin (C) is put into place. In addition, the head (A) and the handle (E) are soldered at their connecting points. Two small plugs (H) close up the openings in the ends of the handle. The total length of the handle is 9 inches. The length of the head 3⅛ inches. The total weight of the mallet is 12 ounces.

The advantage this mallet possesses over others is proper size, being more nearly that of a small wooden carpenter's mallet which some surgeons have used because of its size. It

is balanced properly. It has the right "hang" and "feel." The impact of the mallet on a chisel is not the dull, heavy blow that one gets from the copper mallet or the lead mallet. Then, again, it can be boiled and made perfectly sterile, which is not possible in mallets made of wood or with rawhide faces.

The mallet is efficient, two being in use in large hospitals in this city. One has been used in the largest surgical clinic for the last seven years, during which time it has served its purpose well.

Any instrument maker can manufacture the mallet by following the drawing, which is an exact reproduction of the mid-section of the mallet, changing the dimensions to suit individual ideas.

5751 Prairie Avenue.

5. Much information regarding the Lawrence filter, its construction and operation has been obtained from the annual reports of the Massachusetts State Board of Health for 1893-1901, and also from a valuable paper by Knowles and Hyde (Transactions American Society of Civil Engineers, 46, 1901, No. 906), and the accompanying discussion of this paper by several experts.

The Admission to Membership in County Societies of Those Who Have Been Sectarians.—The *Iowa Medical Journal* says: "There is a whole lot of sentiment being wasted regarding this matter. The object of this reorganization is to broaden the medical profession and encourage those who intentionally or accidentally have cast their lots along sectarian lines, to renounce such selection and join us in making the grand profession of medicine what it should be."

THE NOMENCLATURE OF TOXINS.

Bacterial and other toxins have proved to be of so complex a nature and subject to such alterations that a group of terms relating to them has developed. These terms are not devoid of confusion, owing to their multiplicity and similarity. The word toxin has come to have a limited and technical application. Ehrlich has concluded that it should be applied to those poisonous products of vegetable or animal metabolism by immunization with which one is able to obtain a specific antitoxin. Diphtheria and tetanus toxin, abrin, ricin, etc., are examples of the former, and snake poison of the latter. Toxins must also have a definite structure, that is to say, a haptophorous group by which they link themselves to cells and substances derived from cells, especially antitoxin, and a toxophorous group. This definition, then, excludes such poisonous substances as the vegetable alkaloids, as strychnin and morphin, and poisonous minerals, for which an antibody apparently can not be produced; these are toxic substances, but not toxins.

The bacterial toxins mentioned occur in solution in the cultures of the bacilli and may often be precipitated in an impure form by certain chemicals. It is to be noted that not all pathogenic bacteria secrete demonstrable poisons in culture media, although such organisms in disease may cause intense intoxication, a condition which we can not attempt to explain by the mere mechanical presence of the bacteria in the tissues. It may be that such organisms (typhoid, cholera) contain toxic substances which remain incorporated in the bacterial cells, and become effective only when the latter die or are dissolved. The term toxin has been applied, perhaps loosely, to cultures of the typhoid or cholera organisms which have been killed by heat. We have previously called attention to work showing that when autolysis of typhoid or dysentery bacilli is allowed to occur, a toxic substance goes into solution. The work, however, has not shown that these substances are toxins according to the conception mentioned above.

When Ehrlich undertook to establish a fixed method for estimating the value of diphtheria antitoxin he obtained confusing results, and was forced to make an analytic study of the toxin to clear up certain unexpected variations. For example, a toxin would gradually lose its virulence for the guinea-pig, but would constantly require the same amount of antitoxin to neutralize it. Naturally, it would be expected that as the toxin lost in virulence less antitoxin would be required to neutralize it. Again, a toxin of low virulence would sometimes require, relatively, more antitoxin for neutralization than one of higher virulence. It appeared that a toxin might lose in virulence but keep its original binding power for antitoxin. This indicated that toxin was far from a simple, uniform substance. Some of the phenomena seemed explainable by the assumption that the toxin molecule consists of two groups, one which has the combining power (haptophore) and another in which the toxic power resides (toxophore). This makes it possible to understand that the toxophore group might disintegrate, leaving the binding group still in condition to unite with antitoxin. This degenerated toxin has received the name toxoid, and is, on the whole, not poisonous, having lost its toxophore complex. But as the binding complex is retained it is still able to unite with antitoxin, and when injected into animals is able to unite with the cells and cause the production of antitoxin. In tetanus it is almost necessary to begin immunization with the toxoid or a weakened toxin. The discovery cleared many difficulties and suggested that careful analytic studies of a toxin should be made with the expectation of bringing to light other complexities. This Ehrlich did with the diphtheria toxin and found that he had to deal with a multiplicity of poisons in the same solution; as the toxin became older various degeneration products formed. He devised a method of expressing graphically the constitution of a toxin in the form of a "toxin spectrum," the evolution of which is very intricate. A grasp of the situation may, however, be obtained in the following statement: Having discovered the existence of toxoids, the degree of their affinity for antitoxin became of importance, in differentiating them from toxins. It was assumed that this affinity might be greater, equal to, or less than that of the toxin. For the determination of this a toxin was used which in a given quantity contained 100 toxin units (or fatal doses for the guinea-pig) and 100 toxoid units. The total binding power of the toxoids was then equal to that of the toxins, making a total of 200 binding units. These were completely neutralized, say, with 1 c.c., i. e., 200/200 c.c., of a standard antitoxin. When less than 200/200 c.c. of antitoxin was added some of the binding units of the toxin solution were unbound. It developed that the groups first set free were not toxic, i. e., they were toxoids, and a variety of toxoids which has a weaker affinity for antitoxin than toxin. If it were otherwise, some of the toxin would have been set free and a guinea-pig injected with the mixture would have died. These are the epitoxoids. As less and less antitoxin was added to the quantity of toxin mentioned nothing but epitoxoids was set free until the amount fell below 150/200 c.c.; then toxin began to be freed, and this continued in all mixtures until the quantity of 50/200 c.c. of antitoxin was reached. By this time all the 100 units of toxin had been freed, and 50 units of

toxoids. Carrying the experiment further showed that the remaining binding groups were also toxoids, but since they were the last to be freed they had a stronger affinity for antitoxin than the toxin had, and hence they were protoxoids. Syntoxoids are toxoids equal to pure toxin in their affinity for antitoxin. The epitoxoids are also known as toxons, and are not without toxicity for the guinea-pig, as they are able to cause the paralysis characteristic of diphtheria without other symptoms.

When Madsen and Dreyer injected their mixtures into rabbits it was found that not only the toxins but also the toxons caused acute death. However, by adding what was an excess of antitoxin for guinea-pigs and injecting the mixture into rabbits paralysis, as the only symptom, could be produced. Ehrlich has called this portion of the toxin solution toxonoid—toxic for rabbits, but not for guinea-pigs. Hence toxin, toxon and toxonoid are three toxic constituents of a filtered culture of the diphtheria bacillus. By further refinements in experimentation it was found also that the toxin could be resolved into prototoxin, deuterotoxin and tritotoxin, the differentiation being based on differences in affinity for antitoxin, and that there were also an alpha and a beta modification of each of these, according to the readiness with which they became changed into toxoids.

The work of Madsen and Dreyer is hardly less important in this connection than that of Ehrlich, since they have so fully corroborated and extended his discoveries, especially in regard to diphtheria and tetanus toxin. It is difficult to appreciate the vast amount of painstaking labor which was required to reach the results so briefly expressed above. They seem highly technical and one may be inclined to think they concern only theorists, but it was the realization of these very technical results that led Ehrlich to formulate the side-chain theory of immunity—a theory which has already yielded practical consequences of enormous value. These considerations are of particular interest now in view of the polemic being waged by Gruber on Ehrlich's conception of the toxin structure and the side-chain theory—in fact, on Ehrlich's theories as a whole—a subject to which we may return later.

PROLONGED FREEZING AND GERM LIFE.

While it has been generally conceded for some years that the mere fact of freezing did not kill bacteria, but only rendered them for the time incapable of multiplication, there has been a very general impression that the keeping of bacteria at a temperature below the freezing point for a long period eventually led to their death. Such intensely low temperatures as may be produced by liquid air fail to destroy at least the more resistant forms of bacteria. On the other hand, Sedgwick, Winslow and Park in the course of their investigation of the ice supply of Boston came to the conclusion that ice, even from contaminated water, became sterile after a month or perhaps even less. In a review of their work in the *Boston Medical and Surgical Journal*[1] it is stated that it may be concluded from these investigations that ice more than three weeks old is sanitarily as safe as a well-filtered water supply. Cases of typhoid fever due to ice might naturally be expected to occur, if at all, at the time immediately following the cutting of infected ice. As this is done usually in January, the ice could hardly be held responsible after March, at the latest, for any trouble, even were it known to be infected. It is almost needless to say that this statement attracted wide attention. There had been more than a suspicion that virulent typhoid bacilli might outlive the winter, even though kept below the freezing point for several months. The epidemic of typhoid fever at Plymouth, Pa., which was traced to the stools of a typhoid patient thrown on the snow at least three months before the outbreak of the epidemic, seemed to show this very clearly.

Unfortunately for the peace of mind of those who have felt that ice could be used with impunity in the summer time because of this declaration of the Boston investigating committee, there is a report[2] of an epidemic of typhoid fever due evidently to impure ice which occurred at least nine months after the infected ice had been cut and stored. This epidemic developed at the St. Lawrence State Hospital, three miles below the city of Ogdensburgh, the first patients coming down with the disease on October 2 of last year.

The tracing of the typhoid fever to the ice as the cause of this epidemic seems to be unquestionable. The ice house from which the suspected material was obtained was first opened for use—none of the ice having been previously withdrawn—about a week before the first cases of typhoid developed. During the months of January and February, 1902, when this ice was forming, there were three or four cases of typhoid fever in Ogdensburgh among users of well water. The drinking water of the institution is above suspicion, from both the laboratory and the practical standpoints, since it is from a public water supply, and no cases of typhoid fever occurred among those using it in Ogdensburgh. An examination of the ice showed definite evidence of organic contamination in the form of the colon bacillus.

As the result of this confirmation of the suspicion that there was sewage material in the ice, further investigations were made in the laboratory of the St. Lawrence State Hospital itself, and five colonies of bacteria were found, presenting characteristics resembling the typhoid bacillus. Of these cultures three proved to be of the colon bacillus, one of a bacillus not identified, while the fifth was a pure culture of the typhoid bacillus, as shown by all the generally accepted bacteriologic tests. Under the microscope this bacillus proved to be actively motile with the morphologic appearances of the *Bacillus typhosus*.

There seems no reason to doubt, then, that the typhoid bacilli may live for many months, perhaps even in-

1. Vol. cxlv, p. 557.
2. Amer. Jour. Med. Sci., October, 1903, p. 680.

definitely, in ice frozen at temperatures very near the zero point and kept under the favorable conditions that must exist for its constant preservation at temperatures well below the freezing point when properly stored as far north as Ogdensburgh.

One fact, however, of the Ogdensburgh epidemic deserves noticing, since it indicates that this specific instance can not be taken as positive evidence of the general retention by ice of bacteriologic impurities. Water frees itself in the process of freezing by throwing down its organic contents and foreign matter, and not by enclosing them and freezing them to death. Occasionally, however, masses of foreign substance are entangled in the process of freezing, and become enclosed in the ice. Such was the case with the ice tested at Ogdensburgh, and from the black masses included in its substance the cultures were made. There was no doubt concentration of infection in these inclusions and the rest of the ice may have been comparatively innocuous, though that can not be proven. There is one fact, however, that stands out prominently, viz., mere cold alone does not destroy the germs; therefore, the peril from ice is not altogether an improbable one, especially when macroscopically visible impurities exist.

THE FALLIBILITY OF SCIENTIFIC DICTA.

If one looks about him in the scientific world for the most striking characteristic of our times, he will find it, perhaps, in the systematic organization of investigative work. There has never before been a time when original research has been so carefully planned or so consciously directed as now. The world is tremendously impressed with the results of science attained during the last two centuries, but it would not be surprising, with the immense system of inquiry now in vogue, if during the twentieth century discoveries were made which would exceed in number and eclipse in grandeur those of all the centuries which have preceded.

In the forward march of science, great theories are originated, have their day and are demolished. But it is surprising how often an old theory, thought to be thoroughly extinct, will be exhumed and resuscitated. Like Colonel Bogy of the golf links, a scientific bogy may be "downed" one day, but it is likely to "down" its antagonists the next. The science of chemistry began with alchemy—the attempt of the ancients to manufacture gold out of the baser metals. Gradually the doctrine of the immutability of the "elements" developed and the efforts of the alchemists were believed to be attempts at the absolutely impossible; one who harbored their hopes was regarded as ridiculous. But the physicists and chemists have been making some startling discoveries in the recent past, as the result of which the elements have been shown to be less "immutable" than was thought. Each of them gives off radiations of minute particles, the so-called "electrons" or "ultimate corpuscles," each of which is at least 1,000 times lighter than the atom of H, and each of which, so far as can be made out, is the same as every other particle of the same magnitude, no matter what its source. It may not be true that the "element" radium decomposes into the "element" helium, as has already been asserted, but certain it is that physicists and chemists feel far less certain to-day of the elementary nature of the so-called elements than they have for a hundred years. Indeed, one of the oldest chemists in America was heard to say within a fortnight that, in his opinion, the principal work of the laboratories of physics and chemistry during the next ten years would be devoted to attempts to analyze and synthesize the elements. It is amusing to think of the excitement there would be among the gold-seeking alchemists of the middle ages—wherever they might be at the time—should some one be fortunate enough, in the not too distant future, to take electrons derived, say, from iron and combine them into the precious metal—gold. That such a thing may be suggested even shows to us clearly the great changes which are going on in chemical thought.

Again, there is the doctrine of "spontaneous generation" kept alive for so long by its supporters and especially by the unfortunate Bastian, until it was thoroughly extinguished by the researches of Tyndall and Pasteur. Would it be surprising if this dead doctrine were revivified? Surely no more so than the resurrection of alchemistic dreams. Those biologists who are busily engaged in the application of physical chemistry to the study of protoplasm are already cherishing again the possibility of sometime making living things from things not alive; some of them even dare to say so, and others would like to say so did they not fear that they would be suspected of carrying "bees in their bonnets." Truly, not all theories sleep that have closed eyes!

THE ALLEGED DANGERS OF STRYCHNIA.

In view of some recent criticisms regarding the use of strychnia as a cardiac tonic, it is well to note the other, and what clinical experience shows to be, the truer, side. Benedict[1] finds that strychnia approaches most nearly a strictly standardized remedy, chemically and physiologically; he says that, in his experience, it is the only drug from which a permanent result may be expected without danger or deleterious influence and which yet may be regarded as an artificial spur. He even suggests that strychnia may represent some chemical product of our organism, as caffein represents the alloxur bodies, more especially the xanthin radicle.

Of course, the beneficial use of strychnia implies reasonable care in its use, and his ideas as to this are specified as follows: "One milligram, t. i. d.: tonic dose for small adult, with no indication for marked effect. Two milligrams, t. i. d.: ordinary dose for gastric atony, secretory or motor, or for chronic cardiac weakness, functional or organic. Two milligrams five or six times

1. Therapeutic Gazette, Sept. 15, 1903.

daily: dose for marked cardiac weakness, either in medical or surgical cases; in the latter to give strength rapidly before operation or to prevent collapse afterward. This dosage should rarely be maintained for more than three or four days. Three to four milligrams: single emergency dosage in acute heart failure." Of course, individual circumstances may modify this dosage, but the above is given as near the average safe quantities in conditions mentioned above. Benedict says he rarely continues the use of strychnia or any other powerful drug for over two weeks, or usually for more than one week without interruption, and finds it more effective in this way. He has never yet seen a case of "snappy heart" from the use of strychnia in cardiac disease, though such a condition might result from overdosage, and he suggests that there is a tendency in reviewing our failures to incriminate ourselves and our drugs, and that strychnia may have unjustly suffered in this way.

Within the above limits of safety the danger from the drug must be very exceptional. No class of physicians employs this agent more freely than the neurologists, and it is not from them that we principally hear the warning of its dangers, notwithstanding the fact that the doses given are sometimes almost excessive. An example is the use of progressively increasing doses of strychnia in certain spinal diseases advocated years ago by Jewell and more recently by Hammond and, apparently, without fear of damaging effects. If the system can adapt itself, as it appears it can, to doses of more than a grain of strychnin daily without acute toxic symptoms it would seem that its poisonous effects were subject to some exceptions. While it is a drug that must not be incautiously used, nevertheless it does not deserve all the condemnation it has received. There is hardly any more reliable and useful agent in the pharmacopeia, and if it is as dangerous as some suggest, it is time for a thorough reinvestigation of the subject.

SOUTH DAKOTA LEGAL TECHNICALITIES.

The experience with the new medical registration law in South Dakota is in many respects similar to that of Illinois with its medical registration law. The act exempted all who were in practice at certain dates from the provisions of the law, hence, notwithstanding a special provision to meet such cases, a recent judicial decision makes it impossible to discipline any one who was in practice before that period. It was not anticipated, of course, that the judges would put such an interpretation on the wording of the act, but from this and the Illinois experience it would appear that still more caution will be required in drawing up medical practice acts than has been sometimes the case. It will not do to generally exempt any class, old or new, but the law should specify just what they are exempted from. As it is, there may have to be new legislation both in Illinois and South Dakota to bring a certain class of disreputable practitioners under any legal control. In South Dakota the matter has not yet, so far as we know, been passed on by the highest court and perhaps can not be regarded as entirely settled.

"THE AGE OF PAP."

In an article published not long since in one of our British contemporaries, Dr. Harry Campbell designated the period in which we live as the "age of pap," referring by this to the growing tendency to the omission from our diet of foods which require mastication. The teeth are becoming—to a certain extent at least—more and more *functus officio* organs. The result is that, as a United States official, Dr. Wiley, is lately reported as saying, the human race is becoming toothless. Wiley also includes hair in the cutaneous outgrowths which we are losing, but we trust that, if only for esthetic reasons, it will be a long time before the result he prophesies will be fully brought about. There is no doubt, however, that degeneration of the jaws and teeth, which has been progressing every since man became an intellectual animal and depended less on them for raptorial purposes, is going about as far as is required with our present idea of convenience and beauty. Let us hope that there will be still some people who will chew their food, not only for health reasons, but also for good looks. An English writer has seen some good in the American habit of chewing gum in the exercise it gives the jaws. We are glad there is some virtue in it.

AMALGAMATION OF MEDICAL SCHOOLS.

Last week the well-known Trinity Medical College of Toronto was united with the Medical School of the University of Toronto.[1] The medical faculty of the provincial university, as thus enlarged, contains the ablest medical scientists and practitioners in Ontario, and one of the strongest teaching faculties on this continent. Toronto, in the fusion of her medical schools, has added her example to that of some cities of the United States—an example which may well be seriously considered in some other places. A waste of money, time and energy involved in the organization and maintenance of two or more large medical schools where one would suffice is appalling. The concentration of effort, the saving of expense, the increase in efficiency and, not least, the increase in harmony in the activities of the profession which would result from the amalgamation of medical schools in many of our cities would be of incalculable value in furthering medical education. For successful "marriages" to take place between medical schools, the contracting parties must be high-minded and unselfish. The members of their faculties must care more for the good of their students, for the future welfare of the school and for the profession as a whole, than for their own personal interests. It must not be forgotten, though, that even after fusion has taken place and where the faculties are large, multiple dangers beset the path. Many adjustments have to be made, and there must be concessions on both sides, but an earnest desire to do the best thing, combined with honest open speech, will often overcome the greatest of difficulties of reorganization, especially where mutual respect, mutual consideration and mutual kindness prevail.

1. See Canada news column, this issue.

Medical News.

ILLINOIS.

To Hidden Shansi.—Dr. W. A. Hemingway, Oak Park, sails with his wife from San Francisco for his new field of labor in Shansi, China, on the *Coptic*, October 31.

Alleged Healers Give Bail.—"Drs." Parker and Hall, the alleged magnetic healers who were arrested in Omaha and brought back to Peoria to answer to the charge of swindling, were released on bail of $900 each.

Early Investigator of Hypnotism Dies.—J. Stanley Grimes, prominent in the early investigations of hypnotism in the middle of the nineteenth century and for a time professor of medical jurisprudence in the Castleton (Vt.) Medical College, died at Evanston, September 28, aged 96.

Sanitary Inspection of Illinois Cities.—During the past week Dr. E. F. Baker, inspector for the State Board of Health, has made an inspecton of Taylorville, Pana, Shelbyville, Carlinville, Carrollton, Petersburg, Havana, and Mattoon. The sanitary condition of all these cities is reported as good. A few cases of scarlet fever were found in and near Taylorville, and two cases of diphtheria at Pana, with one death. Havana is free from smallpox after a year's prevalence.

Examination of National Guard Medical Officers.—On September 26 a board consisting of Surgeon-General N. Senn, Assistant Surgeon-General G. Paull Marquis and Major Charles Adams held the first examination of candidates for commissions in the medical department of the National Guard, under the new military code. The examination was held in the Senn Hall, Rush Medical College, and six candidates appeared, four of whom were physicians, one a veterinary surgeon, and one a dentist. Examinations will be held semi-annually hereafter.

Chicago.

Personal.—Dr. Oel S. Misick has given up practice and will engage in banking business in Missoula, Mont.——Dr. V. Pleth has returned from abroad.

Poor Milk Prosecutions.—For selling milk below grade, nineteen dealers were fined from one to twenty dollars each, on October 1, by Justice Gibbons.

Health Department Changes.—Dr. William K. Jaques, head of the municipal laboratory, has resigned, and Dr. F. Eldridge Wynekoop, assistant superintendent, is temporarily in charge of the laboratory.

Hospital Opened.—The Victoria Memorial Hospital and Training School, which occupies the old home of ex-Mayor Swift, on Loomis street, was opened with an address by Dr. Ezekiel P. Murdock, October 2.

September Suicides.—Of the 54 deaths by suicide in September, 16 were caused by carbolic acid, 9 by gunshot wounds, 7 by gas asphyxiation, 6 by opium, 4 by cutting throat, 3 each by hanging, and undetermined poisons, 2 by paris green, and one each by chloroform, formaldehyd, hydrocyanic acid and burning.

Rush College Commencement.—At the quarterly convocation, held October 5, twenty-two were graduated from Rush Medical College (Medical Department, Chicago University). The address was delivered by Prof. L. Sherrington of Liverpool, England, his subject being "Localization of Cerebral Centers in the Ape." The lecture was illustrated by lantern slides.

Illinois Medical College Commencement.—On September 30 a class of 42 was graduated from the Illinois Medical College. The doctorate address was delivered by Hon. Edmund W. Burke; Dr. William C. Sanford, secretary, read the annual report; the dean, Dr. B. Brindley Eads, made the announcement of the graduating class, and the president, Dr. Heman H. Brown, conferred the degrees.

IOWA.

Personal.—Dr. Alvin B. Poore, Cedar Rapids, has returned from Europe.

Coming Examination.—The next examination of physicians will be held in the Capitol building, Des Moines, October 21 and 22.

Osteopaths Want Office.—A petition with five thousand signatures has been laid before the governor, asking that he appoint an osteopath as a member of the State Board of Health.

Infectious Diseases.—During August outbreaks of diphtheria occurred at Des Moines, of scarlet fever at Des Moines and Lost Nation, and of smallpox at Webster City, Massillon Township, Vandalia, Cascade, Runnells, Des Moines Township and Perry Township.

Medicine Sample Distribution Prohibited.—The City Council of Iowa City has passed a resolution making it a criminal offense punishable by fine to distribute broadcast samples of medicine. This action has been taken because a number of children have been made ill by eating or drinking samples of medicine thrown into dooryards by patent medicine men.

KENTUCKY.

Regret Dr. Lewis' Death.—At the meeting of the Daviess County Medical Society at Owensboro, September 15, resolutions were adopted respecting the death of Dr. Charles C. Lewis, Owensboro.

Louisville's Smallpox Record.—During the fiscal year just closed St. John's Eruptive Hospital, Louisville, admitted 1,105 smallpox patients. Of these 16 died, ten from smallpox, two from nephritis, and the others from gastroenteritis, pneumonia and heart disease.

Regulation of College Fees.—Since the catalogue of the Louisville Medical College was sent out the Kentucky State Board of Health has adopted regulations as to fees, etc., to which all medical schools must conform. In conformity to these regulations the dean, Dr. Clinton W. Kelly, announces that the fees of the college will not be less than $55 to any student for the session of 1903-1904.

To Test Status of a So-Called Charitable Institution.—In the fall of 1902 the John N. Norton Memorial Infirmary was sued for damages by a former charity patient who had undergone an operation and who, while under the influence of the anesthetic, was burned by the contact of a hot water bag. The attorneys for the institution, in answering the plaintiff's petition, pleaded that the Norton Infirmary was a charitable institution, and could not, under the laws, be held liable for damages. The plaintiff's attorneys deny that the infirmary is strictly charitable, and allege that it is conducted, at least indirectly, for compensation. Judge Gordon holds that if it is a charitable institution, it is not liable for damages to the plaintiff. The case will go to trial to decide on the character of the institution. This point has never been settled in Kentucky regarding an institution of that character.

Louisville City Hospital Troubles.—Superintendent Dr. Ellis Duncan and Superintendent of Nurses Miss Alice M. Gaggs have been summarily dismissed by the Board of Public Safety. On the return of Miss Gaggs from her annual vacation she found a scandal developed because of alleged immoral conduct on the part of two nurses and three orderlies at the hospital. After an investigation, in which Miss Gaggs asserts the charges were substantiated, the two nurses were discharged. Her action was sustained by Dr. Duncan. The nurses appealed to the Board of Public Safety and were reinstated, but the orderlies were dismissed. Miss Gaggs requested an investigation, which was refused, and without notice she was removed. Dr. Duncan's removal soon followed. Dr. George Jenkins, former secretary of the hospital, is temporarily in charge, and Miss Ziegler, a graduate of the hospital training school, has been appointed superintendent of nurses. At a conference held October 2 it was practically decided that changes in the management of the hospital will be made within thirty days. The deans of the six medical colleges in the city were present and agreed with the mayor and Board of Public Safety that it would be best to have a business man in charge of the hospital, the medical department being in charge of a house surgeon, who will have nothing to do with the business end. He will probably be chosen from the staff of internes, who will be appointed as at present, from the medical colleges.

MARYLAND.

Baltimore.

Bosley Reappointed.—On September 29 Dr. James Bosley was reappointed health commissioner at a salary of $3,000.

Vital Statistics.—During September there were 707 deaths and 767 births in the city. Of the deaths 28 were from typhoid fever, which, with diphtheria and scarlet fever, constituted the chief infectious diseases.

Personal.—Dr. Eugene F. Cordell fell down a stairway, September 28, and was severely injured.——Dr. Jackson Piper has gone to Atlantic City to spend several weeks.——Dr. T. Casper Gilchrist has returned from Europe.

Tuberculosis Exposition.—In connection with the meeting on tuberculosis to be held here in January next there will be

an exposition of appliances for combating infection and promoting cure and a series of popular lectures will be given.

The Herter Lectures.—The Christian A. Herter lecture, the first of the series established by Dr. and Mrs. Herter of New York City a year ago, was delivered by Dr. Herter at Johns Hopkins Physiological Laboratory, October 6, on "The Work of Pasteur."

The New College Year.—The Woman's Medical College opened October 1 with an address by Rev. Donald Guthrie, D.D. ——At the College of Physicians and Surgeons the address was by Dr. Geo. W. Dobbin on "The History of American Obstetrics."——That at the Maryland Medical College was by Dr. Alexander D. McConachie.——At Baltimore University Dr. A. Miller Reid was the speaker.——There was no formal opening at the University of Maryland.

MASSACHUSETTS.

Lynn Prepared for Emergencies.—The new smallpox hospital located near the contagious disease hospital on the outskirts of Lynn is almost ready to receive patients.

Osteopath Fined.—Everett P. Clisby, an osteopath of New Bedford, was fined $200, September 26, for practicing medicine without a license. He appealed and was held in bonds of $500. His defense was that by the title "doctor" he never meant anything but doctor of osteopathy.

Shot and Sandbagged, But Still Fights.—Dr. Frank Sanft, Roxbury, while returning from a professional call, was attacked by a footpad, sandbagged, and as he still resisted, shot through the foot. Notwithstanding his injuries Dr. Sanft was successful in fighting off his assailant.

Personal.—Dr. T. Adolf Jones, Boston, has been appointed professor of pathology and clinical microscopy at Flint Medical College, New Orleans.——Dr. Charles H. Richardson, Pittsfield, has been made a member of the surgical staff of the House of Mercy in that city.——Dr. Walter S. Carr, North Adams, has been compelled to give up practice on account of ill health, and will move to Colorado.

MICHIGAN.

Physician Fined for Delay.—Dr. William J. Hare, Detroit, was fined $5 by Judge Frazer, September 5, for failing promptly to respond to a subpena.

Crippled, But Continues Practice.—Dr. Isaac L. Polozker, Detroit, county physician, slipped while alighting from a car and fell, fracturing his left arm near the shoulder. After the arm was reset and a dressing applied, Dr. Polozker went pluckily to work.

Colleges Open.—Grand Rapids Medical College opened October 1 in its new buildings. The faculty has been increased as follows: Dr. William De Lano, lecturer on hygiene and sanitary science; Dr. Thomas C. Irwin, physical diagnosis; Dr. Lotan C. Read, dermatology; Miss Clara Nichols, general chemistry, and Dr. Joseph A. Heasley, nose and throat.—Michigan College of Medicine, Detroit, opened for the year, September 29. Addresses were made by Drs. William A. Hackett, Hal C. Wyman, and Dayton Parker, Detroit, and Dr. Alonzo B. Cornell, Kalamazoo.

PENNSYLVANIA.

Philadelphia.

Jewish Hospital Dedication.—On Sunday, October 4, an immense crowd attended the dedication of the three new buildings of the Jewish Hospital.

New Site for College.—Ground for a new building has been secured by the College of Physicians at the corner of Twenty-second and Locust streets.

Toy-Pistol Dealers Indicted.—Indictments against three retail dealers were recently returned by the grand jury on the charge of selling toy pistols to minors. Indictments were also returned against two wholesale dealers charging them with supplying the pistols to retailers. The action was prompted by the many cases of tetanus recently caused by pistol injuries.

The City's Health.—The records show that, for the week ended October 3, only two new cases of smallpox occurred. Typhoid fever still continues to a considerable extent, there being 76 new cases within the week, 5 fewer than for the previous week. Diphtheria and scarlet fever persist, there being for the week 60 new cases of the former and 70 of the latter disease.

Clinical Lecturers Selected.—The following have been selected to give the clinical lectures at the Philadelphia Hospital the coming fall and winter: Medical—Drs. Roland G. Curtin, S. Solis-Cohen, John H. Musser and William E. Hughes; surgical—Drs. W. Joseph Hearn and Dr. Orville Horwitz; neurologic—Dr. Charles K. Mills; laryngologic—Drs. R. B. Gleason and G. Morely Marshall; orthopedic—Dr. H. Augustus Wilson; dermatologic—Dr. Henry W. Stelwagon; pediatric—Drs. W. C. Hollopeter and J. Madison Taylor; Röentgen-ray therapeutics —Dr. M. Kassabian.

Pure Food Crusade.—What may be considered an important move in the crusade against the manufacture and sale of impure foodstuffs was recently marked in a suit begun by a retail dealer against a manufacturer of lard. The plaintiff seeks to recover $5,000 damages for injury to her business reputation. The retailer had previously been arrested on the charge of selling adulterated lard, which had been represented by the wholesale dealer as pure, but which, on analysis, was found to contain cottonseed oil and other adulterants. It is said that a number of brewers, distillers and dealers in spirituous liquors, who are to answer to the charge of manufacturing and selling adulterated wares, are to offer the defense that beer and other beverages are not food, and that, therefore, the law of 1895 does not apply to them. It is believed that such a defense will be unavailing, for, if the act cited should not cover the cases, Dairy and Food Commissioner Warren has recourse to two other earlier statutes specifically applying to the adulteration of malt and spirituous liquors. The penalty for the violation of the last-mentioned acts is specific and heavier than for that of the former.

GENERAL.

Navy Medical School Opens.—On October 1 the second session of the Navy Medical School opened in Washington with a class of 26.

Yellow Fever in Texas.—In Laredo, Texas, 37 cases of yellow fever are reported, and 16 of these had been, up to September 29, declared genuine. The situation in Mexico is not reported as particularly changed.

CANADA.

The Unified Toronto University.—The official opening of the new medical building and laboratories of Toronto University occurred October 1, marking the union of the faculties of Trinity and Toronto, old rivals for many years, but now strongly cemented into one, which henceforth will mark Toronto as a medical center of the first rank. The opening address was delivered by Professor Sherrington of Liverpool, President Loudon of the university presiding. The University of McGill was represented by Prof. T. G. Roddick, M.P., and Professor Adami; Queen's University, Kingston, by the Hon. Dr. Sullivan; Johns Hopkins by Profs. W. H. Welch and William Osler; Yale by Prof. R. H. Chittenden; Jefferson by Prof. W. W. Keen; Chicago by Prof. Lewellys Barker; the University of Buffalo by Roswell Park; the University of Michigan by Professor McMurrich, he and Dr. Barker being graduates of Toronto University; Harvard by Prof. Townsend Porter, and the University of Pennsylvania by Prof. A. C. Abbott. According to Professor Sherrington three kinds of workers must stand side by side in order that society may draw due benefit from wells of natural knowledge. First, there is the investigator, the fountain-head of the knowledge that is for distribution. After the investigator comes the teacher to whom it belongs to diffuse the knowledge; and third, there is the applier of natural knowledge. There is a new era dawning when the local university as an institution will be entitled to support from the public means. Professor Sherrington closed a very able address by saying: "So shall these laboratories prove a cornerstone for the upbuilding of a temple of knowledge, and a touchstone for the best ore of intellect within the bounds of this great land." At the close of the able lecture by Professor Sherrington, Professor Loudon called on each of the representatives from sister institutions, commencing with Professor Welch, who one and all expressed their appreciation of being present on such an auspicious occasion, and wishing the new medical faculty godspeed. In the evening in the gymnasium Professor Osler delivered the annual opening address to the students. Although he did not particularly believe in these opening addresses, he was very pleased to be the recipient of the honor on the present occasion. Like Professor Sherrington, he paid a high tribute to the work of Prof. A. B. McCallum of the department of physiology, whom, he stated, had won for himself a world-wide fame by his intricate studies. It was not too much to hope that London and Queen's would affiliate with the University of Toronto. Dr. Osler is a pronounced enemy of worry and warns against taking any thought of the

morrow. At the close of this lecture short addresses were delivered by the dean, Dr. Reeve, and by Dr. J. A. Temple, formerly dean of Trinity Medical College. Dr. Temple stated that after turning out prominent medical men the world over for twenty-eight years, he, like his confrères, did not like too well the thought of amalgamation, but believing it for the best interest of the profession in Toronto and the province of Ontario, they would do all in their power to uphold and advance that interest. Special convocation was held October 2, at which the following distinguished visitors received the honorary degree of LL.D. from the university: William Williams Keen, Philadelphia; William Henry Welch, Baltimore; William Osler, Baltimore; Russell Henry Chittenden, Yale University; Charles S. Sherrington, University of Liverpool; Henry Pickering Bowditch, Harvard University (*in absentia*). In the evening in the university the faculty of medicine tendered the visiting gentlemen a banquet, one of the principal speeches of the evening being delivered by Mr. Alfred Moseley, C.M.G., chairman of the educational commission which is shortly to visit the United States and Canada. Special addresses were also delivered to the students in the two large lecture rooms by Professors Barker, Abbott and Adami.

FOREIGN.

Anti-Alcohol Circular.—The Prussian government has issued an anti-alcohol circular similar to the one on tuberculosis for widespread, gratuitous circulation.

Plague Continues in China.—Both plague and cholera are said to be more serious than before reported near Tien Tsin, China. Foreign military authorities are coöperating in the quarantine of Peptang, a city on the Gulf of Chili, where bubonic plague is very prevalent.

Insurance of Physicians During Epidemics.—The government of a Caucasian province in which typhoid fever is endemic has insured the lives of all the physicians in the district against the fever. The 14 physicians are insured for more than $5,000 each; 2 students for half this sum, and 21 health officers for about $2,000 each.

Industrial Contagion of Syphilis.—The French courts recently decided a case admitting that an employer is responsible for damages in case of the transmission of syphilis by the intermediation of a professional instrument. In the case before the court, a glassblower claimed that he had been infected by the tube passed from hand to hand, but the evidence was not conclusive, and his claim was not allowed.

Consumptives on Mont Blanc.—Dr. Kuss, superintendent of the great public Angicourt sanatorium near Paris, has accompanied a number of tuberculous patients to the Vallot observatory near the summit of Mont Blanc. They expected to stay a week or two for physiologic tests and to determine whether rarefied air is of benefit to consumptives. Dr. R. Bayeux is there also, continuing Hénocque's studies on hematoscopy.

The Plague Epidemic at Marseilles.—Later reports state that no less than 29 workmen employed in the paper factory at Marseilles presented symptoms suggesting the pulmonary form of plague. They had been handling rags imported from Constantinople and dead rats had been found in the bales. Six deaths have occurred, but the energetic measures at once adopted seem to have arrested the epidemic, and the quarantined employes have been released. The factory was burned and all employed about the place were carried to a quarantine station. Two of the nurses tending the plague patients contracted the disease.

LONDON LETTER.

The Etiology of Sleeping Sickness.

The etiology of sleeping sickness or negro lethargy has of late received much attention. Its peculiar geographical distribution—between the valleys of the Senegal on the north and the Congo on the south—suggests a local cause. It has never been known outside this area. But the disease may develop years after leaving the endemic area. A commission of investigation was sent out to Uganda by the Royal Society in 1902. One of the members, Dr. Castellani, reported that in examining the cerebrospinal fluid obtained by lumbar puncture in a well-marked case he found a living trypanosoma. In further investigations he found the organism in 70 per cent. of the cases. As a working hypothesis he suggested that sleeping sickness is due to the trypanosoma and that in the last stages there is concomitant streptococcus infection. Another commission consisting of Lieut.-Col. Bruce, F.R.S., and Dr. Nabarro was then despatched. They arrived in Uganda on March 16, and have now made a "progress report." They adopted Dr. Castellani's method of examination. Ten c.c. of cerebrospinal fluid removed by lumbar puncture were centrifuged. The sediment was examined under the microscope. The trypanosomes were never very numerous (in some cases only one was found in several slides), but they were found in every one of 40 cases examined and at all stages of the disease. The cerebrospinal fluid of the general population was found not to contain trypanosomes. It was also shown that the parasites were present in the blood of all the patients suffering from the disease. The suggestion has been made that the trypanosomes are conveyed by some biting insect. Experiments show that the Uganda tsetse fly can carry the trypanosoma from animal to animal.

Roman Catholicism and Leprosy; Leprosy in Colombia.

In maintaining the fish hypothesis of leprosy Mr. Jonathan Hutchinson has often adduced facts tending to show that the fast days of the Roman church are in many parts of the world conducive to the spread of the disease. In a recent letter to the *Times* he makes a strong point out of the prevalence of the disease in Colombia. Here the earliest Spanish settlements were made, and, according to tradition, the first cases of leprosy on the American continent occurred. The disease is now frightfully prevalent there, much more prevalent than in India, which has been described as "the land of the leper." In Catholic Colombia where the consumption of fish receives a stimulus from religious ritual there are 70 lepers per 10,000. In India where large sections of the population have a prejudice against fish there are only 6 lepers per 10,000. Mr. Hutchinson asks what explanation those who believe that leprosy spreads by contagion have to offer. The Colombians do not expose themselves to the risk of contagion more than the Hindus, and during the last 30 years more energetic measures of segregation have been enforced in the former country. Further, the great prevalence of the disease in Colombia corresponds to the condition of fish supply. In many inland districts the natural supply of fish is deficient. Here, as in mid-Europe of the middle ages, an artificial demand creates a supply in bad condition. Moreover, fast days occur all through the year, during many months of which fresh fish may be out of season and not obtainable.

The Plague in India: The Rising Epidemic.

During the last week of August the mortality from plague has much increased in the Bombay Presidency, the deaths rising from 2,838 to 5,568. In Central India there has been an increase from 131 to 331 and in Mysore from 331 to 535. In the whole of India the mortality has risen from 3,613 to 6,817.

Correspondence.

Postmortems.

CHICAGO, Sept. 29, 1903.

To the Editor:—Referring to your editorial of September 5, on "Compulsory Postmortems," it seems to me worth while to emphasize the fact that permission for postmortems can frequently, if not usually, be obtained if the friends are duly considered and properly approached. It would certainly be a salutory custom from the layman's point of view if it were traditional to hold postmortems on all the dead, especially if the physicians in charge were expected by custom to write their colleagues to be present. The wholesome effect that this "facing the music" has in hospital life in calling forth every known diagnostic effort, and leading to due appreciation of responsibility because of the fear of criticism at the morgue table by one's colleagues, is well known to all who have been internes. If the layman fully understood the inward significance of the phrase "Dead men tell no tales" autopsies would be much more general than they are, and, incidentally, I see no reason why some lay representative of the family should not be present if it were so desired.

From the general practitioner's point of view there is no need to make postmortems on such as die after a typically defined course of some well-known disease, as such pathology may be seen every day in the larger hospitals, but sometimes the diagnosis remains obscure to the end or ill-defined complications arise that the truly scientific physician would like cleared up if possible. He is often able by the exercise of a judicious finesse to make a fairly complete autopsy through a four or

five inch incision made between the ensiform and the umbilicus. If the physician has the tact and takes the trouble to explain how very small the incision will be, that it will be neatly closed with white silk—untidy work on the dead is a desecration unworthy a physician—that all organs will be replaced if desired, that nothing but the abdominal wall will be cut when this can be promised, that the family will be welcome at the autopsy if this be practicable, as it sometimes will, and that the embalmer may do his work at the same time, then it will be found that many autopsies may be secured that are lost by neglecting to remove the belief that it is necessarily an extensive mutilation, leaving many visible marks. Where the brain is concerned a cleanly worker can promise that the incision will be entirely hidden by the hair and no evidence of the examination be noticeable. JAMES W. WALKER, M.D.

A Universal Practitioner's License.

LOS ANGELES, CAL., Sept. 4, 1903.

To the Editor:—In THE JOURNAL, August 29, p. 568, among the unsuccessful candidates in the Tennessee reports of registration, candidate 54, a graduate of the College of Physicians and Surgeons, Baltimore, class of 1876, failed with a per cent. of 70. This fact substantiates the remarks of Dr. T. A. Borton in his article "The Turning Down of the Old Practitioner" published in THE JOURNAL, August 22, p. 505, with the exception that here the other unsuccessful candidates were nearly all recent graduates. Not knowing the questions asked and judging from the markings alone, I have nothing to say against this particular examining board; but I would like to have the following remarks reach those members of the profession who have more influence and power than has the average general practitioner. Something more is needed than a higher curriculum for the elevation of the profession, something that will make the American public respect the well learned doctor and not the well-to-do "Dock," as Dr. W. E. Quine classified them in one of his eloquent speeches. Any school with the best facilities and longest course in this country or abroad furnishes only the key to knowledge. Many of the best teachers in medicine to-day did not know the difference between an acid and an alkali at the time of their graduation years ago. The majority of successful practitioners, who were good students ten years ago, would not be able to pass a technical examination to-day with a higher per cent. than 60, and I do not think it right to make the old practitioner suffer for the pre-existing laxity of the laws in any shape or manner, and all these different board examinations in the eyes of the public, prove to be a lack of self-confidence somewhere, by not recognizing the credentials of a reputable medical college from one state to another. The more privileges there are granted to improve the condition of the general practitioner, the more encouragement there will be for progressive study and investigation, and the fewer there will be of those who resort to quackery, criminal operations, fraudulent certificates and unethical conduct toward one another for the sake of the dollar. To remedy this, or at least the greater part of it, I beg to suggest the following rough sketch:

The American Medical Association shall elect one member in each state for the term of one year. These gentlemen shall constitute the Medical Council of the United States. Their aim shall be to elevate or to better the educational, moral and material condition of the American practitioner. They shall hold regular conventions at least twice a year. At their first convention they shall at once declare all those colleges which are now members in good standing in the Association of American Medical Colleges entitled to grant an interstate certificate to each of their graduates, after passing a satisfactory examination under the state board of examiners, in which the state member of the council shall act as chairman at the time of the examination, and on the same principles conducted now by the different boards. This interstate certificate shall entitle the holder to practice medicine and surgery all over the Union, or, at least, in those states that will hold membership for reciprocity in the Medical Council at that time. Those states that will join the Medical Council later on will have to open their doors to the same candidates that passed the council's examination before their membership began.

This council shall also issue an interstate certificate to every old practitioner in good standing and holding a state license who is a member of the United States Medical Council, without an examination.

This council shall have judiciary power to decide on questions arising from time to time in the different states and relating to medical colleges, state board examinations, state medical societies and all other interests in the general welfare of the profession at large. The decision of the council in every case shall be final.

Considering the advance in surgery made by American surgeons, I am sure that foreign countries will seek reciprocity with the United States in the near future.

423 California Street. S. B. LYON, M.D.

State Boards of Registration.

American Confederation of Reciprocating, Examining and Licensing Medical Boards.—A meeting of this body is called at the Southern Hotel, St. Louis, for October 27. An invitation is extended to all licensing boards to be represented at the meeting. The secretary of the confederation is Dr. B. H. Harison, Sault Ste. Marie, Mich.

Preliminary Examinations.—A committee of the Michigan State Board of Registration in Medicine met at Detroit to look into the work being done by the different medical colleges of that city. The committee formulated a standard for the admission of students to the medical colleges of the state. The law requires that matriculants must at least be graduates of high schools having a classical course. Those who are not will have to pass an examination.

Marriages.

EMIL C. BECKER, M.D., to Miss Ida Grace Beal, both of Chicago, September 16.

EDWARD HICKS HUME, M.D., to Miss Lotta Carswell, both of Baltimore, September 24.

LOUIS P. HAMBURGER, M.D., to Miss Freda Cohn, both of Baltimore, September 20.

HENRY MAYNADIER FITZHUGH, M.D., to Miss Mary Aldridge, both of Baltimore, September 23.

ADELBERT H. BENSON, M.D., Faxon, Okla., to Miss Ella M. Rahnapop of Chicago, September 23.

J. M. BIEDLER, M.D., Bridgewater, Va., to Miss Ina E. Long, Shenandoah County, Va., September 16.

FREDERICK WILLIAM PARKER, M.D., to Miss Grace Elizabeth Peabody, both of Chicago, September 23.

BENJAMIN R. PARKE, M.D., Wellsville, Ohio, to Miss Roberta Reynolds of Buffalo, N. Y., September 23.

EUGENE GATES, M.D., Two Rivers, Wis., to Miss Gertrude Cordelia Marsh of Chicago, September 17.

HENRY E. HASKINS, M.D., Kingman, Kan., to Miss Bertha B. Knappenberger of Penalosa, Kan., September 20.

DANIEL F. ROYER, M.D., Orange, Cal., to Mrs. Hettie Wilbur of Los Angeles, at Kingman, Ariz., September 16.

ARTHUR N. MCKEEVER, M.D., Romney, W. Va., to Miss Katherine Keller, at Frostburg, Md., September 23.

HARVEY GRANT BECK, M.D., Baltimore, to Miss Katherine Elizabeth Clagett, at Blairsville, Pa., September 23.

SIMON FLEXNER, M.D., New York City, to Miss Helen Whitall Thomas, at Bryn Mawr College, Pa., September 17.

WILLIAM VAN VALZAH HAYES, M.D., New York City, to Miss Mary Coulbourne Conner of Altoona, Pa., September 9.

MERIWEATHER LEWIS ANDERSON, M.D., of Albemarle County, Va., to Miss Annie Tatum, at Richmond, Va., September 23.

Deaths.

Calvin Skinner, M.D. Dartmouth Medical College, Hanover, N. H., 1841, surgeon of the One Hundred and Sixth New York Volunteers in the Civil War, some-time president of the Northern New York Medical Society and the Franklin County, N. Y., Medical Society, died at his home in Malone, N. Y., September 24, aged 85.

John M. Allen, M.D. University of Vermont, Burlington, 1890, a member of the American Medical Association, surgeon to Brightlook and St. Johnsbury hospitals, member of the Vermont State Medical Society, who was injured in an automobile accident, September 17, died at his home in St. Johnsbury, Vt., September 18.

J. B. Winn, M.D., of Macon, Mo., in whose honor the Macon County Medical Association gave a banquet a few years ago, the oldest physician in Northern Missouri, died at the home of his daughter in Kirkwood, Mo., September 23, aged 88.

Daniel B. Howard, M.D. Albany (N. Y.) Medical College, 1865, ex-president of the Warren County Medical Society, died suddenly at his home in Warrensburg, N. Y., September 21, from neuralgia of the heart, aged 62.

George Doughton, M.D. College of Physicians and Surgeons, Baltimore, Md., 1884, of North Wilkesboro, N. C., died at the University Hospital, Baltimore, September 24, after an operation for cancer of the neck, aged 38.

Frederick J. Halton, M.D. Long Island College Hospital, Brooklyn, 1883, after a long invalidism from rheumatism, died at his home in Brooklyn, N. Y., September 24, from valvular heart disease, aged 45.

Stephen Terry Biggers, M.D. Southern Botanico-Medical College, Macon, Ga., 1835, a pioneer of Atlanta, Ga., died at Cornelia, Ga., September 21, from pleurisy, after an illness of twelve days, aged 92.

George W. Crider, M.D. Medical College of Indiana, Indianapolis, 1879, of Buck Creek, Ind., died at the Home Hospital, Lafayette, Ind., September 21, from heart disease, after a long illness, aged 68.

Samuel T. Dodd, M.D. Western Reserve University, Cleveland, Ohio, 1867, died at his home in East Palestine, Ohio, September 22, from heart disease, after a lingering illness, aged 68.

Margaret Eleanor Peery, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1897, of Monticello, Iowa, died at Butte, Montana, from acute pleurisy, September 19, aged 47.

William E. Naughton, M.D. Long Island College Hospital, Brooklyn, 1896, died at his home in Brooklyn, N. Y., September 23, from pneumonia, after an illness of one week, aged 29.

Robert H. Gordon, M.D., quarantine officer of Norfolk, Va., during the yellow fever epidemic of 1855, died suddenly at his home in that city, September 22, from apoplexy, aged 77.

Lincoln A. Stewart, M.D. Boston University School of Medicine, 1895, of Clinton, Mass., was drowned in the Penobscot River, near West Brookville, Me., September 20, aged 55.

Ernest W. Spinney, M.D. Chicago Homeopathic Medical College, 1896, died at his home in Reed City, Mich., September 22, from appendicitis, after a short illness, aged 35.

James A. Johns, M.D. Medical College of the State of South Carolina, Charleston, died suddenly at his home near Westminster, Ga., September 11, from paralysis, aged 71.

Joseph L. Hagerty, M.D. Rush Medical College, Chicago, 1870, died at his home in Topeka, Kan., September 24, after a long illness due to exposure during the recent flood.

George W. Colby, M.D. National Medical College, Washington, D. C., 1869, for more than 35 years a practitioner of Sutton, Vt., died at his home in that place, September 13.

Edward C. Swift, M.D. University of Pennsylvania, Philadelphia, 1868, died at his home in Easton, Pa., September 23, after an invalidism of nine years, aged 60.

William C. Wells, M.D., resident physician at the Reed City (Mich.) Sanitarium, died suddenly at the institution, September 19, from apoplexy, aged 70.

John T. Sankey, M.D. University of Pennsylvania, Philadelphia, 1847, died at his home in Tharin, Ala., September 18, after a protracted illness, aged 77.

E. G. W. Simpson, M.D. McGill University, Montreal, 1901, died at his home in Lennoxville, Que., September 23, from typhoid fever, aged 27.

Henry C. Sheppard, M.D. Hahnemann Medical College, Philadelphia, 1878, died at his home in Germantown, Philadelphia, September 23, aged 63.

Auburn C. Henry, M.D. Memphis Medical College, 1859, died suddenly from heart disease at his home in Woodlawn, Ala., September 24, aged 60.

Orsemas Deremo, M.D., an eclectic physician of Elon, Iowa, died at his home in Center Township, September 20, after a long illness, aged 78.

Mary A. Boyd, M.D. Hahnemann Medical College, Chicago, 1886, died suddenly at her home in Los Angeles, Cal., September 21, aged 62.

John Person, M.D., died at his home in Fremont, N. C., September 18, aged about 75.

Lucius C. Coke, M.D. Medical College of Virginia, Richmond, 1859, died at his home near Palmyra, N. C., September 10, aged about 70.

Jedediah T. French, M.D., 1840, of Knoxville, Iowa, died at the home of his daughter in Hutchinson, Kan., September 23, aged 80.

William P. Rothrock, M.D. Jefferson Medical College, Philadelphia, 1842, died at his home in Floral, Kan., September 13, aged 83.

Miscellany.

The Union of the Profession in New York.—The following correspondence and action make it look very promising for an amalgamation of the two organizations in New York:

SYRACUSE, N. Y., May 28, 1903.

Dr. F. H. Wiggin,
President of the New York State Medical Association.

My Dear Doctor:—At the last meeting of the Medical Society of the State of New York the committee on conference appointed to confer with a similar committee of the New York State Medical Association, after making its report, was continued and instructed to await the action of the American Medical Association at New Orleans before considering further the methods of amalgamating the regular profession of the State of New York.

At a recent meeting of the American Medical Association radical action was taken removing the obstacle which prevented unification. Appreciating the fact that no further barrier stands in the way of unifying the profession of the State of New York into a single state society, the committee representing the Medical Society of the State of New York would respectfully ask the New York State Medical Association that further conference with its representatives be arranged, with the object of speedily settling on a definite plan which shall form the basis for amalgamation of the two existing bodies. In making this request the committee representing the Medical Society of the State of New York assures the association of its earnest desire to increase the influence of the state profession by the action suggested; that it would further state to that body that it is ready to suggest to he Medical Society of the State of New York that it amend its charter to continue, consolidate and amend Chapter 138 of the Laws of 1806, Chapter 94 of the Laws of 1813 and Chapter 452 of the Laws of 1900 for the purpose of cultivating and advancing the science of medicine, the promotion and protection of public health, and the establishment of a death benefit fund for the dependents of the members of the Medical Society of the State of New York. That it feels justified still further in assuring the association that it will recommend to the state society the method of organization founded on the plan suggested by the American Medical Association and considered by the joint conference when in session in April, 1902, and that all other matters of detail which must be considered before final action can be taken by the respective societies must, of necessity, become subjects for conference.

The committee asks for careful deliberation in conference, that both the society and the association may in the near future be able to present completed and satisfactory plans to the state bodies for ratification. Respectfully,

(Signed) Henry L. Elsner, chairman; A. Jacobi, A. Vander Veer, George R. Fowler, committee.

NEW YORK, June 10, 1903.

Dr. Henry L. Elsner,
Chairman Committee on Conference,
Medical Society of the State of New York,
Syracuse, N. Y.

My Dear Doctor:—I have received your communication of the 28th requesting the appointment by our association of a committee to confer with your committee relative to plans for uniting our state bodies, signed by yourself, Drs. A. Jacobi, A. Vander Veer and George R. Fowler, and I shall take pleasure in presenting it to our council at the earliest practicable moment for consideration and such action as they may see fit to take on it, as, under our constitution and by-laws, matters of importance are so referred.

Respectfully yours,
(Signed) Frederick Holme Wiggin, president.

In pursuance to the above a special meeting of the Council and Fellows of the New York State Medical Association was held in the New York Academy of Medicine, at which there were 70 present. After reading the above correspondence the following preamble and resolutions were offered by Dr. Joseph D. Bryant and were unanimously adopted:

WHEREAS, The members of the New York State Medical Association desire a union of the medical profession in the State of New York, and

WHEREAS, It is deemed expedient, for the attainment of this purpose, to make further effort to bring together the New York State Medical Association and the Medical Society of the State of New York under the name of "The Medical Society of the State of New York."

Resolved, That a committee of five be appointed by the chair, and said committee is hereby empowered to do whatever is necessary and expedient to bring about such a union in a just and equitable manner, and

Resolved, That the committee so empowered may confer, cooperate and unite with a committee of the Medical Society of the State of New York for the purpose of forming said union of the two medical organizations, and

Resolved, That a copy of these resolutions be transmitted to the secretary of the Medical Society of the State of New York, with a request that their conference committee be granted similar powers.

The following committee was appointed: Drs. E. Eliot Harris, chairman, Julius C. Bierwirth, Alexander Lambert, Parker Syms, and Wisner R. Townsend.

Bearing on this matter is the action of the committees appointed by the Cortland County Medical Society and Cortland County Medical Association, held September 4, when the following resolution was adopted:

WHEREAS, About 35 or 40 per cent. of the members of the Cortland County Medical Society are members of both the society and association,

Resolved, That we believe that we express the sentiment of nearly all the profession of the county in the desire for the harmonious union of the two medical organizations of the state, since we believe our influence and power in the state in obtaining medical legislation and preventing the enactment of harmful laws, would be greatly enhanced thereby, and we recommend that all proper measures be taken to bring about this end.

The committee for the Cortland County Medical Society consisted of Drs. F. W. Higgins, H. T. Dana and J. W. Whitney.

The committee for the Cortland County Medical Association consisted of Drs. S. J. Sornberger, C. D. Ver Nooy, and F. D. Reese.

Book Notices.

CONSUMPTION A CURABLE AND PREVENTABLE DISEASE. What a Layman Should Know About It. By Lawrence F. Flick, M.D., Founder of the Pennsylvania Society for the Prevention of Tuberculosis. Cloth. Pp. 295. Price, $1.00. Philadelphia: David McKay. 1903.

This little volume is, as its title indicates, an attempt to instruct the laity in regard to this disease of which the public as well as the profession have of late years heard so much. There has been an immense amount of literature and a considerable amount of misconception on the subject. This work is intended to correct the latter and to give a fair and unexaggerated view of the disorder and its prevalence. It is a little difficult to steer clear of the popular and professional tuberculophobia on the one hand and of too great laxity as regards the real peril of the disease on the other. On the whole we think Dr. Flick has taken a judicious middle course. Any one who reads his book through ought to have at its close a fairly well-balanced mind as regards the dangers and the possibilities of tuberculosis. Reading a special chapter alone would not be sufficient. Dr. Flick evidently takes the view that there is a decided difference between bovine and human tuberculosis and that the dangers of ingestion of tubercle bacilli in meat and milk are not by any means as great as held by some authors. We would not say, however, that he encourages an absolute lack of precautions in this respect. The point he makes is that the experiments that have been made have been persistent, animals have been continuously fed on tubercles and every possibility for the contraction of the disease has been employed, whereas in the ordinary use of meat and milk as done by the human species in the ordinary course of life, the conditions are quite different. He says that perhaps the strongest argument that may be advanced against the view that meat and milk are sources of the seed supplied for human tuberculosis is found in clinical experience. No indisputable case in which human tuberculosis has been thus contracted has been put on record. Of course, this is a matter of individual judgment, but we ourselves doubt whether any of the reported cases will stand a searching criticism if other possibilities of infection were thoroughly excluded. The book is very neatly gotten up, nicely printed, of convenient size and should do good.

A TEXT-BOOK OF PATHOLOGY. By Alfred Stengel, M.D., Professor of Clinical Medicine in the University of Pennsylvania. With 394 Text Illustrations, Many in Colors, and 7 Full-page Colored Plates. Cloth. Pp. 933. Price, $5.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

This work appeared first in September, 1898. The favor with which it has been received by the profession is well shown by the fact that it has reached its fourth edition in less than five years. In this fourth edition the most important changes and additions to be noted are found in the chapters on the bacterial diseases and immunity and allied processes. The enormous amount of work being done in this line throughout the world is constantly adding to our knowledge and makes frequent revision of text-books necessary. In this volume the above-mentioned subjects have been brought up to date, and the various theories of immunity, especially Ehrlich's side-chain theory, are clearly set forth. Mention is also found of the recent work of Reed and Carroll on yellow fever. Not the least important addition to be noticed is an appendix of about forty pages on pathologic technic. This includes examination of fresh specimens; methods of hardening and staining special tissues; blood stains and bacteriologic examinations. It adds materially to the value of the work as a whole, which is an excellent one and can be recommended.

HIGH-FREQUENCY CURRENTS IN THE TREATMENT OF SOME DISEASES. By Chisholm Williams, F.R.C.S. Edin., M.R.C.S. Eng. Cloth. Pp. 222. Price, $2.75 net. London and New York: Rebman, Ltd. 1903.

This is an English work on electrotherapy. The author started, as he says, with some skepticism as to the value of these currents, but after an extensive trial became convinced of their great usefulness in some cases. The book is largely made up of a description of the apparatus. The diseases in which he has found the treatment beneficial are briefly noticed at the end and include diabetes, gout, chronic rheumatism, obesity, hysteria, anemia, chlorosis, neurasthenia and pulmonary tuberculosis. The latter is treated of at considerable length, and he finds this treatment of marked benefit. He is strongly of the opinion that the application or use of these currents in tuberculosis sanitaria will greatly increase the number of cures. Dyspepsia is also discussed at some length. Among local diseases he mentions lupus, both of the tubercular and erythematous types, eczema, sciatica, headache, etc., and malignant growths.

LESSONS IN DISINFECTION AND STERILIZATION. An Elementary Course of Bacteriology, Together with a Scheme of Practical Experiments Illustrating the Subject-matter. By F. W. Andrewes, M.A., M.D. Oxon., F.R.C.P. Lond., D.P.H. Cantab., Lecturer on Pathology, Pathologist and Sanitary Officer to St. Bartholomew's Hospital, London. Cloth. Pp. 222. Price, $1.05. London: J. & A. Churchill. Philadelphia: P. Blakiston's Son & Co. 1903.

We have experienced considerable satisfaction in the perusal of this little work, which is a remarkably clear and readible statement of the general facts in regard to sterilization and disinfection. As the author says, it will probably be of some service, not only to nurses but also to practitioners who have not had the opportunity for a regular course in bacteriology. While it does not cover the ground as fully and in details as does the work of Rosenau, it is a convenient and concise statement of the general methods of disinfection and also gives some accounts of the bacteria concerned in infection, full enough indeed to meet the ordinary wants of the general practitioner for information on these subjects. The book is one that may be recommended.

PROTOZOA AND DISEASE. By J. Jackson Clarke, M.B. Lond. Cloth. Pp. 177. Price, $2.50 net. New York: Wm. Wood & Co. 1903.

While this book has only recently appeared and is perhaps the best available account of animal disease-producing organisms that we have at the present time, the progress in this line has been so rapid that we find many subjects are omitted. Still, it is an excellent little treatise and can be recommended. The book is well illustrated, well written and will be valuable for ready consultation by pathologic workers and others.

AN ENGLISH HANDBOOK OF THE PARIS MEDICAL SCHOOL. By A. A. Warden, M.D., Visiting Physician to the Hertford British Hospital, Paris. With Prefatory Letters by Lord Lister and Prof. W. W. Keen. Paper. Pp. 72. Price, 2s. London: J. & A. Churchill. Philadelphia: P. Blakiston's Son & Co. 1903.

Physicians proposing to visit Paris to see clinical work will find this little book of considerable value. It gives the location of the various public and private hospitals, and tells how to reach them; gives a list of the attending physicians and surgeons and hours of attendance; also information in regard to the practice of medicine in France, and in regard to other matters of special interest to medical men visiting the French capital.

Association News.

List of new members for the month of September, 1903:

ARIZONA.
Tyroler, Adolph, Williams.

ARKANSAS.
Crutcher, William, Pine Bluff.
Donnell, R. A., Malvern.
Johnson, R. F., DeQueen.
Hayes, Sr., John W., Eureka Springs.
Logan, B. C., Mirrilton.
Rowland, W. T., Arkadelphia.

CALIFORNIA.
Bloch, Herbert I., San Francisco.
Cunnane, W. B., Santa Barbara.

COMING MEETINGS.

Tri-State Medical Society of Alabama, Georgia and Tennessee, Oct. 13-15.

Vermont State Medical Society, Bellows Falls, Oct. 15-16.

New York State Medical Association, New York City, Oct. 19-22.

Congress of State and Provincial Boards of Health of North America, Baltimore, Oct. 23-24.

American Public Health Association, Washington, D. C., Oct. 26-30.

Hawaiian Territorial Medical Society, Honolulu, Nov. 7.

Oklahoma Territory Medical Association, Oklahoma City, Nov. 11.

Wayne County (Ind.) Medical Society.—At its regular session in Richmond, September 3, the society adopted a new constitution by an almost unanimous vote.

Vermont State Medical Society.—The nintieth annual meeting will be held at Bellows Falls, October 15 and 16, under the presidency of Dr. Edmund M. Pond, Rutland.

Crawford County (Iowa) Medical Society.—Physicians of Crawford County met at Denison, September 11, and organized a county medical society, with Dr. George S. Waterhouse, Charter Oak, president, and Dr. Andrew Randall, secretary.

Washburn-Sawyer-Burnett County (Wis.) Medical Society.—The first annual meeting was held at Spooner, September 8. Dr. John B. Trowbridge, Hayward, was elected president; Dr. Joseph P. Cox, Spooner, vice-president, and Dr. E. Rudolph Herring, Shell Lake, secretary and treasurer.

Chicago Medical Society (Southern District).—At the annual meeting of this branch of the Chicago Medical Society, September 30, Dr. Edward B. Hutchinson was elected president; Dr. O. Paul Chester, vice-president; Dr. Winfield S. Harpole, secretary, and Dr. Charles P. Pinckard, treasurer.

Northern California and Southern Oregon Medical Association.—Physicians met at Cedarville, Cal., August 28, and organized this association, with the following officers: Dr. Herbert T. Risdon, Alturas, Cal., president; Dr. R. E. Lee Steiner, Lakeview, Ore., vice-president; Dr. Hilderbrand, Cedarville, Cal., secretary, and Dr. Alexander Gibson, Alturas, Cal., treasurer.

Bi-Parish (Natchitoches and Red River, La.) Medical Society.—This society was organized at Coushatta, September 15, and the following officers elected: Dr. Clarence E. Edgerton, Coushatta, president; Drs. Samuel H. Scruggs, Cloutierville, and W. F. Sibley, Robeline, vice-presidents; Dr. Hendricks, East Point, secretary, and Dr. James McGoldrick, Coushatta, treasurer.

Cole County (Mo.) Medical Society.—This society was organized at Jefferson City, September 17, with 17 members, with the following officers: Dr. Robert E. Young, president; Dr. Jefferson L. Thorpe, vice-president; Dr. Gustave Ettmueller, secretary; Dr. William A. Clark, treasurer, and Dr. Charles P. Hough, delegate to the Medical Association of the State of Missouri, all of Jefferson City.

Jasper-Newton County (Texas) Medical Society.—Physicians of Jasper and Newton counties recently organized a medical society with the following officers: Dr. Hardy R. Hancock, Jasper, president; Dr. Jefferson D. Yates, Kirbyville, vice-

president; Dr. Thomas E. Stone, Jasper, secretary and treasurer, and Drs B. F. Yates, Jefferson D. Yates, Jasper, and G. P. Sutton, Burkeville, censors.

Brunswick County (N. C.) Medical Society.—Dr. Frank H. Russell, Wilmington, councilor for the Third District, organized a county medical society at Southport, September 18, on the plan recommended by the American Medical Association. The following officers were elected: President Dr. Erastus G. Goodman; vice-president, Dr. Walter G. Curtis, Southport, and Dr. J. A. Dosher, Southport, secretary and treasurer.

Putnam County (Ohio) Medical Society.—The physicians of the county met recently at Ottawa and organized a county medical society with the following officers: Dr. John C. McClung, Leipsic, president; Dr. C. F. Douglas, Kalida, vice-president; Dr. Wiley D. Hickey, Leipsic, secretary; Dr. Warren F. Reed, Ottawa, treasurer, and Drs. Charles E. Beardsley, Ottawa, Harry A. Lewis, Continental, and Alva L. Paul, Ottawa, censors.

Wright County (Iowa) Medical Society.—Dr. Charles H. Churchill, Fort Dodge, councilor for the Tenth District, met the physicians of the county at Eagle Grove, September 11, and assisted in the organization of a county medical society. Dr. Joseph H. Sams, Marion, was elected president; Dr. James W. Garth, Clarion, vice-president; Dr. E. D. Thompson, Eagle Grove, secretary and treasurer, and Dr. W. C. McGrath, Eagle Grove, censor.

Sioux County (Iowa) Medical Society.—Dr. Edward E. Dorr, Des Moines, councilor for the Seventh District, met fifteen physicians of the county at Alton, September 10, and organized a county medical society on the plan recommended by the American Medical Association. Dr. Albert De Bey, Orange City, was elected president; Dr. Ferdinand J. Smith, Alton, vice-president, and Dr. C. S. McCarty, Hawarden, secretary and treasurer.

Shelby County (Mo.) Medical Society.—Members of the old county society recently reorganized the society and elected the following officers: Dr. William Carson, Shelbyville, president; Dr. J. D. Smith, Shelbina, vice-president; Dr. L. W. Dallas, Hunnewell, secretary and treasurer; Drs. Frank K. Roy, Hagers Grove, Adolphus G. Wood, Lentner, and W. W. Owen, Oakdale, censors, and Dr. William Carson, delegate to the Medical Association of the State of Missouri.

Carroll County (Iowa) Medical Society.—The physicians of the county met with Dr. Charles H. Churchill of Fort Dodge, councilor for the Tenth District, at Carroll, September 15, and organized a county medical society with the following officers: Dr. J. Jordan Deshler, Glidden, president; Dr. Albert S. Gockley, Carroll, vice-president; Dr. Alois Kessler, Carroll, secretary-treasurer, and Drs. Robert R. Williams, Manning, Johan B. H. Feenstra, Arcadia, and Bernard C. Kelley, Carroll, censors.

Juneau County (Wis.) Medical Society.—At a meeting of the physicians of the county held in Elroy, September 10, a medical society was organized with the following officers: Dr. John B. Edwards, Mauston, president; Dr. Robert W. Hoyt, New Lisbon, vice-president; Dr. Arthur T. Gregory, Elroy, secretary and treasurer; Dr. Eugene H. Townsend, New Lisbon, delegate to the Wisconsin State Medical Society, and Drs. Charles S. Smith, Elroy, James E. Smith, Mauston, and Charles H. Golden, Wonewoc, censors.

Tri-Parish (La.) Medical Society (Claiborne, Webster and Bienville).—This society met at Arcadia, September 17. Drs. Francis M. Thornhill, Arcadia, James C. Willis, Homer, and Joseph E. Knighton, Homer, were appointed a committee to revise the constitution and by-laws so as to conform to those of the state society. The report of this committee and the question of applying to the state society for a charter will be discussed at the next regular meeting, which will be held at Homer on the second Thursday in January, 1904.

Jefferson County (Wis.) Medical Society.—About 20 physicians of the county met at Jefferson, September 8, and organized a county medical society, adopting the constitution and by-laws recommended by the American Medical Association. The following temporary officers were elected pending the granting of a charter: Dr. William W. Reed, Jefferson, president; Dr. C. E. Lauder, Johnson Creek, secretary and treasurer, and Drs. Carl R. Feld, Watertown, William A. Engsberg, Lake Mills, and Urban P. Stair, Fort Atkinson, censors.

Organization in Louisiana.—Dr. J. M. Barrier, Delhi, president of the Louisiana State Medical Society, has begun a series of tours through the principal unorganized parishes of the state in the interest of medical organization. The physicians of these parishes are being circularized in advance The first organization meeting of this series was held at Winsboro, Franklin Parish, September 24, when the Franklin Parish Medical Society was organized. There are now about 20 out of a total of 59 parishes, and applications for charters are coming in briskly.

Newaygo County (Mich.) Medical Society.—Dr. Bartlett H. McMullen, Cadillac, councilor for the Ninth District, met the physicians of the county at Newaygo, September 10, and organized a county medical society to be in affiliation with the state and national organizations. The following officers were elected: Dr. Nicholas De Haas, Fremont, president; Dr. William H. Barnum, Fremont, vice-president; Dr. F. Holmes Brown, Newaygo, secretary; Dr. Charles Whitehead, Newaygo, treasurer, and Drs. Fred Yonkers, Woodville, Morey L. Teeple, Grove, and Drummond Grant, censors.

Montgomery County (Texas) Medical Society.—Dr. John T. Moore, Galveston, councilor for the Ninth (South Texas) District, met the physicians of the county at Conroe, September 14, and organized a county medical society on the plan recommended by the American Medical Association, with an initial membership of 12 and the following officers: Dr. William P. Powell, Willis, president; Dr. Henry W. Waters, Montgomery, vice-president; Dr. Juriah F. Collier, Conroe, secretary and treasurer, and Drs. R. Walter Smith, Clinesburg, George W. Stevens, Willis, and William N. Hooper, Conroe, censors.

Dane County (Wis.) Medical Society.—Dane County medical men met in the senate chamber, Madison, September 17, and organized a county medical society with the following officers: President, Dr. Cornelius A. Harper, Madison; vice-president, Dr. William F. Pinkerton, Mazomanie; secretary and treasurer, Dr. Reginald H. Jackson, Madison; censors, Drs. J. C. Cutler, Verona, Charles S. Sheldon, Madison, and Daniel B. Collins, Madison. A committee composed of Drs. Charles S. Sheldon, Theodore W. Evans and Mila B. Sharpe, all of Madison, was appointed to consider the adoption of the constitution and by-laws recommended by the American Medical Association.

South Dakota (Mitchell District) Medical Society.—The physicians of the Mitchell District, comprising Douglas, Hanson, West Hutchinson, West McCook, West Turner, South Sanborn, Jerauld, Buffalo, Aurora, Brule, Lyman and Davison counties, met, September 24, at Mitchell, for the purpose of reorganizing along the lines suggested by the American Medical Association. Sixteen members were present and applications had been received from thirty-seven physicians within the district. Officers were elected as follows: President, Dr. John W. C. White, Plankinton; vice-president, Dr. Bert Menser, Bridgwater; secretary, Dr. E. Frank Reamer, Mitchell; treasurer, Dr. Charles A. Bower, Mitchell, and censors, Drs. George A. Clousen, Bridgewater, Orville D. Pharon, Emery, and Roscoe H. Goodrich, Chamberlain. The next meeting will be held at Chamberlain in December.

Medical and Chirurgical Faculty of Maryland.—At the semi-annual meeting of the Medical and Chirurgical Faculty of Maryland, held at Blue Mountain House, September 24 and 25, the president presented some interesting statistics regarding the public medical libraries of Baltimore. Dr. Charles Wardell Stiles, Boston, read a paper on the dwarf tapeworm, *Hymenolepsis nana*, a new species infecting man, of which about 100 cases have been found in this country. The symptoms are similar to those in the other forms, and the only efficient remedy discovered is the male fern. An eloquent address was made by Dr. J. N. McCormack, Bowling Green, national organizer of the American Medical Association, on the advantages of organization of the profession, and a committee of nine was appointed to report the necessary changes in the constitution. Dr. D. W. Cathell, Baltimore, read a paper in which he praised the wisdom of the change from the code of ethics made at New Orleans, and predicted that the homeopaths would become merged in the regular profession by it, to the great advantage of the latter. Dr. Guy L. Hunner, Baltimore, reported 35 cases of tuberculosis of the urinary system in women, showing, contrary to the usual opinion, that it is more frequent in the upper part of the tract (kidney and ureter) than in the lower (bladder). Diagnosis is often obscure. The results of surgical treatment are very encouraging. Dr. J. McPherson Scott, Hagerstown, read a paper on "Needed Amendments in the Medical Practice Act," and a committee of eleven was appointed to report on the subject at a special meeting to be held at Baltimore, November 15.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

Sixteenth Annual Meeting, held in Chicago, Sept. 22-24, 1903.

(*Continued from page 872.*)

Acute Perforated Gastric Ulcer.

DR. H. HOWITT, Guelph, Ont., presented a paper on this subject. Acute gastric ulcer perforation, as understood by him, refers to those cases in which Nature fails to prevent the escape of gas, liquid or other contents of the stomach by adhesion of the part to adjacent structures. He believes that the diagnosis should be made without difficulty when the perforation occurs in a young, anemic girl, whose previous history indicates the presence of an ulcer. Diagnosis should not be difficult in the majority of the other cases, for there is generally a history of gastric distress after meals, and frequently other symptoms to indicate the trouble. Sudden intense pain in the epigastrium, pronounced shock, rigidity of the abdominal wall and the thoracic character of the respiratory movements aid in arriving at a correct conclusion; and, if in addition to these the initial pain radiates in a certain direction, and the position of greatest suffering changes and gradually takes a downward course in the abdomen, the diagnosis may be made without delay. In the rare instances of rupture of the gall bladder or perforation of the duodenum in which the symptoms closely resemble those of gastric perforation, the indications for prompt surgical treatment are practically the same. In perforation of the anterior wall to the left of the median line, the material, and consequently the pain, follows a course along the inner side of the descending colon. In all other situations they follow along the descending colon toward the pelvis.

Morphia before a diagnosis has been made often prevents timely recognition and prompt action. Until the general practitioner becomes more familiar with the true import of the initial symptoms successful operations will not be common.

Symptoms indicate the position of the ulcer in the stomach definitely enough for all practical requirements. Before perforation takes place, when the ulcer approaches the peritoneal coat, a local sensitive area of peritonitis is produced, and it is very sensitive to pressure or other form of irritation. Hence the posture of the patient is that which avoids pressure and keeps the contents of the stomach away from the ulcer. For instance, when the ulcer is on the anterior wall, the patient is more comfortable when lying on the back, and so on. When it is on the anterior wall, point pressure of a superficial character may, by causing severe pain, indicate the exact position. The pain, when severe, tends to radiate in certain directions, according to the position of the ulcer. If near the pylorus and on the anterior wall, to the right, or to the right and downward. On other parts of the anterior wall, to the left and to the left and upward to shoulder. On posterior wall, to back immediately behind its situation and to right or left, according to whether it is right or left of spinal column, and upward to interscapular space. A large incision, collapse of the distending coils of intestines by temporary enterotomy and evisceration render the work easy and more expeditious, and with less damage to the delicate parts than is possible by any other method. When the perforation is large, drains are used in each flank, and in the pelvis, not through a large incision, but through separate stabs.

Beside a brief synopsis of each of his former operations already reported, the paper contains a report of his fourth case, in which the perforation was on the anterior wall. It was closed with fine silk suture. His method of sight inspection and flushing of all parts of the abdomen and pelvis with a large forcible stream and drainage was carried out. The patient recovered and is well to-day.

DISCUSSION.

DR. C. H. MAYO, Rochester, Minn., said that he and his brother had had several cases of perforating gastric ulcer of the type described. Their experience had been that there was about an even number of perforations in the pyloric region of the stomach; also in the first portion of the duodenum, and that the symptoms and results were about the same in either position. The character of the ulcer was about the same. In the stomach perforations, as a rule, the chronic irritation had been of such a nature that it was almost impossible to close the perforation.

DR. JOHN B. MURPHY said the proper time to operate on perforating gastric ulcer was before the peritoneum had been irreparably injured. This may not be the first day. Many times the stomach is not full when perforation occurs. Furthermore, the stomach contents are less septic and less irritating than those of any other portion of the alimentary canal, therefore the time may be longer in perforating gastric ulcer than in typhoid perforation.

Should the Uterus and Ovaries Be Removed in Operating for Double Pyosalpinx?

DR. C. C. FREDERICK, Buffalo, N. Y., read a paper on this subject. He first briefly reviewed the history of operative procedures. After an experience of about fifteen years with the various surgical procedures gynecologists are in a position to decide accurately the amount of pain, discomfort and illness due to disease of the various anatomic parts of the woman's sexual apparatus. It is not necessary to sacrifice all of these organs when they are not all hopelessly diseased. The duty of the gynecologist is to afford his patient the greatest possible relief from her symptoms with the least mutilation, and the preservation of every organ possible to enhance the most perfect performance of all bodily functions. As much of the healthy ovarian tissue as possible should be left if it be only the eighth part of an ovary. If the condition is known to be tubercular, the uterus should certainly be removed. But even if both tubes and uterus are taken out all the ovarian tissue possible should be saved. The uterus should not be removed if it can be retained.

DISCUSSION.

This paper was discussed by Drs. Robert T. Morris, Rufus B. Hall, Walter B. Dorsett, Miles F. Porter, Byron Robinson, W. D. Haggard, Albert Goldspohn, E. C. Dudley, J. H. Carstens, Frederick Blume, John B. Murphy and Charles L. Bonifield, all of whom favored the conservation of as much ovarian tissue as possible in operating for pyosalpinx.

The Indications and Technic of Vaginal Drainage for Suppuration in the Pelvis.

DR. ALBERT GOLDSPOHN, Chicago, discussed the chief routes by which infection enters the female pelvis and described the type of pathologic changes resulting from each route. While pelvic cellulitis is rare and of little significance in non-puerperal infections, via the tubes, it is the leading or primary anatomic change in puerperal infections, via the lymphatics. When vaginal evacuation of the pus in pelvic suppuration needs to be followed by a more radical secondary operation, in many cases it enables the inflammation in the associated uterus or tubes, or ovaries, to subside during the interval, so that they need not be removed, as would have been deemed necessary if a radical operation had been performed in the first instance or during the acute stage. Vaginal drainage helps to save life in cases that have become too feeble for a radical procedure to be applied at once. Preliminary drainage improves their condition so that they can stand a radical operation later, with no higher rate of mortality than obtains after abdominal section in other cases that are not so reduced. This operation should never be a puncture with a trocar, knife or scissors, but always a transverse incision into the posterior cul-de-sac, preferably with the thermocautery. From this entrance, as a vestibule, laterally located purulent accumulations, if not yet opened, are best attacked by a finger assisted by forceps. Only a small proportion of the cases so treated by him have required another operation, except when the infection was from the vermiform appendix.

DISCUSSION.

DR. EDWARD J. ILL said he began to use vaginal drainage fifteen years ago, and while he was not opposed to this peculiar method, long experience had taught him there were better methods. Cases of cellulitis should be opened from below, if

possible, and the sooner the better. But the drainage of tubal and ovarian abscesses is different and is by no means curative.

Dr. D. Tod Gilliam said that unless cellulitis existed he did not think there was justification for vaginal drainage.

Dr. H. W. Longyear, Detroit, said that to get rid of pus in the cellular tissue there was no question about the propriety of vaginal drainage. Further, if a woman is *in extremis* from long-continued suppuration and prolonged fever, and can not stand a radical operation, the pus should be drained at first through the vagina, but this measure should not take the place of a radical operation later.

Dr. J. Henry Carstens, Detroit, agreed with Dr. Longyear.

(To be continued.)

PENNSYLVANIA STATE MEDICAL SOCIETY.

Fifty-third Annual Meeting, held at York, Sept. 22 to 24, 1903.

The meeting was called to order by the president, Dr. William M. Welch, Philadelphia, and addresses of welcome were delivered by Mayor M. B. Gibson of York and Dr. N. C. Wallace, president of the York County Medical Society.

Professional Ethics.

Dr. J. N. McCormack, Bowling Green, Ky., national organizer of the American Medical Association, delivered an address on this subject, in which he lamented the animus so frequently shown by physicians toward other practitioners. He detailed the plan of organization recommended by the American Medical Association and made a plea for clean physicians, physically, morally and mentally.

Misleading Text-Books.

The committee appointed to examine school text-books on physiology and hygiene reported as follows:

The school text-books on physiology and hygiene contain many errors and much misleading information and very serious omissions. The books, as a whole, can not be recommended, although some few are good. We are sorry to be compelled to say that the books supervised by the Woman's Christian Temperance Union committee are the most reprehensible.

If the object of the woman's committee is the teaching of prohibition, then let them openly and honorably designate their books by truthful titles, and not resort to the contemptible method of using a scientific term to cloak an ethical principle.

It is evident to any fair-minded observer that while a grain of strychnia is a poison, the one-hundredth part thereof is not. It is absurd to teach that cider, beer, wine, etc., in any dose is a poison, whereas, we all know that a tumbler of pure alcohol is. This is but the morbid expression of fanatics, who are guided by zeal rather than by wisdom.

The committee recommends that a committee be appointed to consider the advisability of state supervision of the school text-books pertaining to anatomy, physiology, hygiene and all allied subjects.

The Orations.

The address in surgery was delivered by Dr. William L. Estes, South Bethlehem, who urged the necessity for keen discrimination between operable and inoperable cases.

The address in obstetrics was delivered by Dr. John G. Clark, Philadelphia.

The address in hygiene and state medicine was delivered by Dr. Seneca Egbert, Philadelphia, in which he stated that the population of the districts in the United States in which a system of mortality registration had been organized had increased from 19,659,440 in 1890 to 28,807,269 in 1900, with a decrease in the death rate in the registration areas from 19.6 to 17.8 per 1,000. He forcibly demonstrated the value of improved sanitary regulations, such as purification of the water supply, supervision of milk and food, quarantine regulations, etc., and dwelt at considerable length on the value of preventive measures in contagious and infectious diseases.

The address in neurology was delivered by Dr. Charles B. Mayberry, Retreat, Pa., in which he considered the means of securing better results in the treatment of the insane, which he believed would result from the carrying out of the following suggestions: 1. More extensive instruction in psychiatry, both didactic and clinical. 2. The construction of small psychopathic hospitals for the separate treatment of the acute curable insane. 3. The organization of a system of out-patient departments by which the discharged patients may be kept under observation for one year after leaving the institution. 4. The creation of a central laboratory for the investigation of the pathologic conditions underlying mental disease.

The address in ophthalmology was delivered by Dr. E. B. Heckel, Pittsburg. He said that the drugs which were used twenty-five years ago, e. g., mercury, nitrate of silver and atropin, stand out prominently in optical therapeutics to-day, the advance consisting in the new and improved methods of using them. The treatment of glaucoma, he stated, had made but little progress and iridectomy was still to be preferred to sympathectomy, massage being a valuable adjunct, and cytology, while it has been used but a short time, gives indications of good results in sympathetic ophthalmia.

The address in medicine was delivered by Dr. H. M. Neale, Upper Lehigh, who believes the most important therapeutic factors in the treatment of pulmonary tuberculosis are fresh air, sunlight, rest and cleanliness in conjunction with proper food and careful medical supervision. He believes that cures can be effected as well at home as in the higher altitudes. He describes in detail the method of treatment at the White Haven Sanitarium, one of the important factors being large quantities of milk and eggs. In addition, internal doses of creosote and iodin compounds, and inunctions of olive oil, wintergreen oil and other oils are administered.

Social Features.

At the Tuesday evening session the president's annual address was delivered by Dr. William M. Welch, Philadelphia, after which the society was given a reception at the Country Club by the York County Medical Society.

Wednesday afternoon the society visited the York Water Plant, where an address was delivered by Mr. George W. Fuller, New York, on the subject of "Water Filtration," followed by a reception given by the York Water Company at the Country Club, and in the evening a theater party given by the York County Medical Society.

Thursday evening the members were given an automobile excursion to the Penn Park musical entertainment, and on Friday morning an excursion to the Gettysburg battlefield.

The New Officers.

The following officers were elected: President, Dr. William B. Ulrich, Chester; vice-presidents, Drs. Isaac C. Gable, York; Philip Y. Eisenberg, Norristown; Fred W. Coover, Harrisburg; William A. Marsh, Mt. Pleasant; secretary, Dr. Cyrus Lee Stevens, Athens; assistant secretary, Dr. Theodore B. Appel, Lancaster; treasurer, Dr. George W. Wagoner, Johnstown; board of trustees, term ending 1906, Drs. Richard Armstrong, Lock Haven; Isaac C. Gable, York, and William S. Ross, Altoona; delegates to the American Medical Association, Drs. George W. Guthrie, Wilkesbarre; William S. Foster, Pittsburg; Alex. R. Craig, Columbia; Webster B. Lowman, Johnstown; alternates, Drs. Walter Lathrop, Hazleton; John B. Donaldson, Canonsburg; William M. Guilford, Lebanon; James N. Richards, Fallsington; Samuel Wolfe, Philadelphia; James H. Montgomery, Erie; Erasmus V. Swing, Chester, and William M. Beach, Pittsburg.

The place of the next annual meeting was fixed at Pittsburg, and Dr. W. S. Foster was appointed chairman of the committee on arrangements.

The Importance and Necessity of Industrial Hospitals.

Dr. W. B. Lowman, Johnstown, urged in this paper the importance of the establishment of hospitals in conjunction with all the large industrial institutions, as a humane measure and also as a sound business investment, as employes thus cared for would be less likely to institute legal proceedings for slight injuries and in perhaps hopeless cases.

The Medical Expert Witness.

Dr. G. W. Wagoner, Johnstown, in this paper, argued that experts selected by the court would give better satisfaction than witnesses paid by parties to testify for the benefit of their side of the case.

State Medical Board Examinations.

Dr. A. O. Kelly, Philadelphia, laid especial stress on the importance of the examiner being a practical physician familiar

with the progress of medicine. He believed that the questions should be limited to the practical and applied aspects of the subject, and should not be purely academical. He recognized the value of a general knowledge of the general principles of medicine and in no sense recommended the abolition of didactic lectures. He believed practical tests in addition to the written examinations, or the submission to the student of a number of case histories for study, discussion and suggestion would be a valuable augmentation to the examination. When a candidate is asked to give the treatment for a certain condition, he should be required to set forth his reasons therefor.

(To be continued.)

AMERICAN ACADEMY OF RAILWAY SURGEONS.

Tenth Annual Meeting, held in Chicago, Oct. 1 and 2, 1903.

This organization met under the presidency of Dr. L. Sexton, New Orleans. The academy has about 140 members and is an energetic scientific organization.

Conservatism in the Treatment of Crushing Injuries.

DR. JERE L. CROOK, Jackson, Tenn., reported three cases, showing how aseptic and antiseptic technic have reversed conditions, substituting salvation for sacrifice, and limbs of living flesh and bone for those of wood, cork and leather.

DRS. R. HARVEY REED, EVAN O'NEILL KANE, A. H. BRUMBAUGH, H. M. DEAN, F. A. BUTLER and O. B. QUINN talked along the line of the conservation of limbs and of as much tissue as possible.

Injuries of the Large Joints.

DR. I. V. CROSBY, Stuart, Iowa, reported two cases to emphasize the necessity of carrying out the strictest antiseptic precautions from start to finish. By so doing the function in many severely injured and infected joints can be saved even in the rural districts.

Physical Examination of Railroad Employes.

DR. H. B. JENNINGS, Council Bluffs, Iowa, urged the responsibility of the surgeon making these examinations for the company, and a lengthy discussion was elicited, during which different methods of examining railroad employes were brought out.

The Value of an Injury.

This was the title of the president's address, delivered by Dr. L. Sexton, New Orleans. He cited cases to illustrate verdicts for various elements of injury. The railway surgeon can materially lessen the loss or damage incident to injuries by careful, skilful and painstaking attention to each case.

Ocular and Aural Examination of Railroad Employes.

DR. FRANK ALLPORT, Chicago, submitted a report and the resolutions on this subject recommended by the American Medical Association, which were referred to a committee and, on its favorable report, were subsequently adopted.

Other papers read were as follows: "Rheumatism in Connection with Minor Injuries of the Back," on how to differentiate the conditions, by Dr. A. Wilson, Alva, Okla.; "Traumatic Influence in the Production of Movable Kidney," an exhaustive treatise, by Dr. M. L. Harris, Chicago; "Radical Cure of Hernia," by Dr. E. W. Andrews, Chicago, and "Fracture of the Humerus," by Dr. F. A. Butler, Harvard, Neb. The latter described a recovery brought about by means of massage, electricity and constitutional treatment after one and a half years of post-fractural paralysis.

In a symposium on head injuries, papers were presented by Drs. C. H. Mayo, John E. Owens, Haldor Sneve, J. F. Pritchard, W. U. Cole, A. L. Wright and Ira B. Bartle.

Diet in Its Relation to Surgical Cases.

DR. A. B. BRUMBAUGH, Huntington, Pa., said that a healthful diet in general, to aid and enable men and women to attain to their highest capacity mentally and physically, should be simply nutritious, and consist of such articles as were readily, quickly and perfectly digested. It should be mainly of fruits, vegetables simply cooked and the tallow-bearing meats. All excess and doubtful and harmful articles should be discarded, and the diet in surgical cases should conform strictly to the simple type of healthy living.

The secretary presented a letter from Dr. J. N. McCormack relative to the practicability of the academy becoming affiliated with or a branch of the American Medical Association. The communication was referred to a committee, which subsequently reported that the time was not ripe for the adoption of the plan proposed, and, on motion, the action of the committee was concurred in by the academy.

Officers.

The following were elected officers: President, Dr. Samuel C. Plummer, Chicago; vice-presidents, Drs. A. L. Wright, Carroll, Iowa, and W. U. Cole, Columbus, Ohio; secretary-treasurer, Dr. Thomas B. Lacey, Council Bluffs, Iowa; assistant secretary, Dr. H. B. Jennings, Councils Bluffs, Iowa; editor, Dr. D. S. Fairchild, Des Moines, Iowa. Place of meeting, Chicago; time to be decided by the executive committee.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Leg Ulcers.

The treatment of ulcers of the leg, according to Fischkin in *Med. Standard*, consists, 1, in the removal of conditions which may induce or favor necrosis; 2, the production of conditions which will favor the healing process as much as possible. The general outline of treatment consists, according to the author, in:

1. Aseptic cleansing of the leg.
2. Elevation of the leg and application of bandages to remove the venous stasis.
3. The application of remedial agents to induce healthy granulations.
4. The application of such remedies as will favor normal cornification.
5. The application of such remedies to surrounding tissues with a view to healing associated conditions, such as eczema, which may be caused by venous stasis.

In carrying out the first indication the leg should be bathed with soap and water unless great eczema is present, in which case alcohol dressings may be used, or a boric acid or 5 per cent. liquor alum. acetatis or a solution of hydrogen peroxid may be substituted.

These indolent, anemic ulcers must be stimulated in order to promote the formation of healthy granulations. This may be done by syringing the ulcer with hot water or a 1 to 2,000 potassium permanganate solution. This syringing should be followed by an iodoform dressing or the base of the ulcer painted with pure tincture of iodin or the application of unguentum hydrarg. rubrum, balsam of Peru or other stimulating remedies.

If the granulations project too high, caustics and astringents must be applied, such as argenti nitras, 10 per cent. Gangrenous ulcers are to be first cleansed with a hot potassium permanganate solution, followed by the application of a few drops of the following combination:

℞.	Chloralis hydratis	3iiss 10
	Camphoræ	3iss 6
	Glycerini	℥iss 45

M. Sig.: Apply locally.

An iodoform dressing is then applied.

Epithelization and cornification may be encouraged by carefully dressing the ulcer and producing drainage in order to prevent the accumulation of the secretions; or the base of the ulcer should be painted with a 2 to 4 per cent. solution of silver nitrate followed by bismuth subnitrate dermatol or ichthoform dressing. The ulcer is then covered with a guttapercha dressing to aid drainage and to prevent the adhesions of dressings. The surrounding eczemas must be treated. If

the eruption is vesicular or in the stage of serous discharge pastes must not be employed, but in their stead a dry powder as follows:

℞. Zinci oxidi
Talci venet.
Amyli, āā 3iiss 10
Acidi borici .....gr. xlv 3
M. Sig.: Apply locally.

In the dry form of eczema some tar preparation is better, as follows:

℞. Olei cadini
Olei rusci
Spiritus
Spts. etheris, āā.....3iiss 10
M. Sig.: Apply locally.

The author also recommends Unna's paste prepared as follows:

℞. Zinci oxidi 3x. 40
Gelatin 3v 20
Glycerini .....℥i 30
Aq. destil. .....℥iiss 75
M. Sig.: Apply locally with a soft brush, changing the dressing in 3 to 10 days.

In the ordinary ulcers accompanied by pain the following is recommended as a dressing:

℞. Tinct. benzoini comp. 3iv 15
Balsami peru. 3ii 8
Lanolini 3x 40
Ext. belladonnæ .....gr. xxx 2
M. Ft. unguentum. Sig.: Apply locally.

As a local application in syphilitic ulcer the author recommends the mercurial plaster; or if the ulcer is not clean bathe with a mercurial bath and dust with calomel. Iodids should be given internally.

Some authors recommend the following combination in the treatment of syphilitic ulcers:

℞. Hydrarg. chloridi mitis 3i 4
Ichthoformi 5ss 2
Petrolati 3viss 26
M. Sig.: Apply locally; or:
℞. Iodol .....℥i 30
Sig.: Apply freely to the ulcer.

Dysmenorrhea.

The palliative treatment of dysmenorrhea, according to Bjorkman in *Merck's Archives*, is necessarily entrusted to the general practitioner, consequently the treatment is more or less symptomatic, while the radical treatment leading to its cure lies in the province of the specialist. The first step, according to the author, is to gently promote elimination by proper evacuation of the bowels if there is a tendency to constipation. The use of opium or morphin should never be resorted to. Codein and dionin may be used in their stead. He also condemns the use of alcoholics. In well-nourished women cerium oxalate may be given in six-grain doses (.40)) every hour previous to the beginning of the flow and continued until the pain has ceased. Pulsatilla is also recommended, given in 10-minum (.65) doses of the tincture four times a day. This is said to quickly relieve the spasms due to uterine disorders. The following combination is recommended by the author:

℞. Tinct. pulsatillæ .....℥i 4
Syr. aurantii .....℥i 30
Aq. destil. q. s. ad .....℥iv 120
M. Sig.: One teaspoonful four times a day.

In neurotic individuals a combined treatment of bromids and antipyrin is serviceable or the bromids alone given as follows:

℞. Pot. bromidi 3iiss 10
Sod. bromidi 3iss 6
Ammon. bromidi 3i 4
Syr. aurantii corticis.....℥iiss 75
Tinct. rhei 3iiss 10
Aq. destil. q. s. ad.....℥viii 240
M. Sig.: One tablespoonful before meals in one-half a glass of water.

In dysmenorrhea of anemic or spasmodic nature viburnum is of great benefit.

℞. Ext. viburn, prunifol. flu. .....℥i 30
Sig.: One teaspoonful three times a day; or:
℞. Chloralis hydratis .....gr. lxxv 5
Tinct. belladonnæ .....gtts. xxx 2
Ext. viburn. opul. flu.....℥i 30
Elix. simplicis q. s. ad.....℥iv 120
M. Sig.: One or two teaspoonfuls in sweetened warm water every hour until relieved.

The author also recommends stypticin as curative if given for long periods. He advises it in doses of grain ¾ to 1½ (.05 to .09) four or five times a day. In smaller doses it may be given beginning four or five days before the usual time for menstruation, giving a full dose the day previous to the usual time for the flow.

It may be given combined as follows:

℞. Stypticin .....gr. xx 1|30
Ext. belladonnæ
Ext. hyoscyami, āā.....gr. 3¾ |25
Euquinini .....gr. xl 2|65
M. Ft. pil. No. xx. Sig.: One pill three times a day.

Dionin is recommended administered in the form of a suppository combined as follows:

℞. Dionin .....gr. ss-2/3 |03-.04
Ext. cannabis ind. .....gr. iss |09
Butyr. cacoa q. s.
M. Ft. suppos. No. i. Sig.: One such to be inserted into the rectum two or three times a day. [The dose of cannabis indica is rather large.]

The foregoing suppository is valuable in the treatment of dysmenorrhea of young girls, where local treatment can not be properly carried out. The following may be used per vaginum:

℞. Dionin .....gr. ½ |03
Ichthyol .....gr. iii |20
Butyr. cacoa q. s.
M. Ft. suppos. No. i. Sig.: One such to be inserted into the vagina two or three times a day, if necessary, to relieve the pain. Dionin is also recommended by the mouth as a palliative in dysmenorrhea as follows:

℞. Dionin .....gr. vss |35
Aq. amygdalæ amar. .....3iv 15|
M. Sig.: Fifteen drops two or three times a day; or:
℞. Dionin .....gr. ss |03
Salipyrin .....gr. x |65
Acetanilidi .....gr. ii |12
M. Chartula No. i. Sig.: One such powder three times a day.

[Dionin is ethyl-morphin hydrochlorate. It is a powder, faintly bitter, soluble in about seven parts of water, two parts of alcohol, and twenty parts of syrup. Stypticin is cotarnine hydrochlorate. It is a yellow powder, soluble in water or alcohol. It is recommended as a uterine sedative and as a hemostatic.]

Chronic Pharyngitis.

The following combinations are recommended by *Jour. des Pract.* in the treatment of chronic pharyngitis:

℞. Sodii boratis 3ii 8
Tinct. myrrhæ 3i 4
Infusi cocæ foliæ .....℥viii 240
M Sig.: Use as a gargle every two hours; or:
℞. Potassii chloratis 3iiss 10
Infusi rubi fol. .....℥iv 120
Infusi cochleariæ (couch grass) .....℥ss 15
M. Sig.: To be used as a gargle.

Abortive Treatment of Furuncles.

Reich, in an abstract in *Med. Age*, states that positive results are obtained by the treatment of boils with superheated dry-air. The heat is directly injurious to pathogenic organisms; active hyperemia of the tissues and consequently increased resistance to bacterial invasion is induced. The skin is sterilized and dangers to reinfection rendered less probable. According to the author's statement, in no case where the treat-

ment was begun early did suppuration or tissue necrosis take place. The infiltration of the surrounding tissue disappeared more rapidly than ordinary in abortive cases. Reinfection in the tissue surrounding the boil never occurred. In cases of general infection the tendency to fresh boil formation was greatly diminished. He states that this form of treatment reduces the tension in the infiltrated tissue and relieves the pain as a result.

Medicolegal.

Physician to Determine Necessity for Information.—Section 4659 of the Revised Statutes of Missouri of 1899 provides that a physician or surgeon shall be incompetent to testify concerning any information which he may have acquired from any patient while attending him in a professional character, and which information was necessary to enable him to prescribe for such patient as a physician or do any act for him as a surgeon. The Supreme Court of Missouri, Division No. 2, says, in the case of State vs. Kennedy, that it takes it that the physician or surgeon must, as a general rule, under the statute, determine for himself whether the information acquired by him from his patient is necessary for him to prescribe for such patient, and, in the absence of some showing to the contrary, the presumption must be indulged that the information in question was necessary for that purpose; otherwise, he would not desire it. To rule otherwise would be to usurp the prerogative of a physician learned in his profession, which the court has no inclination or right to do. The court adds that, of course, it does not mean to say that it will not pass on questions which are apparent to the ordinary observer, and to one not learned in the sciences of medicine and surgery, which have nothing whatever to do with the case under consideration, and hold them not privileged.

Representations as to Health and Medical Treatment.—The Supreme Court of Michigan says, in the case of Blumenthal vs. Berkshire Life Insurance Company, that the law is settled that in a representation, contained in an application for insurance, that the assured is in good health, or that he has not been attended by a physician or consulted one professionally, the answer is to be construed as meaning, in the one case, that he has not suffered an illness of a serious nature, tending to undermine the constitution, and that a state of health is freedom from disease or ailment that affects the general soundness or healthiness of the system seriously. And as to representations as to treatment by physicians, the omission to state a treatment by a physician for some temporary indisposition does not avoid the policy. In this case the trial judge charged the jury that it is not the duty of an applicant for insurance to advise the insurance company of every time he consults a physician for some temporary indisposition; but it is his duty to advise them, in answer to that question, every time that he has consulted a physician relative to any serious ailment; and that if they found that the disease with which the insured was suffering when he made his application was such a disease as would affect his general health then it was his duty to have advised the company that he had been attended by a physician. The Supreme Court thinks this was clearly within the rule as above laid down.

Exclusion of Immigrant for Favus of Finger Nails.—The United States Circuit Court for the Southern District of New York says, in re Neuwirth, that on certificate of the proper examining medical officer, the board of special inquiry unanimously voted to exclude the alien immigrant in question in this case as having a loathsome disease, viz., favus of the finger nails. His father presented a sworn petition for a writ of habeas corpus averring that his son was not suffering from a loathsome and dangerous contagious disease, but that his disease was curable and slight, and that he had improved since he arrived, and was almost cured. He also presented the affidavit of a physician to the effect that while the condition of the immigrant's finger nails was not normal, he was doubtful whether he was suffering from favus; that, if he was, a slight operation would work a cure; and that in his opinion favus, in this form, was not a "loathsome" nor a "dangerous contagious" disease. On this record the court thinks that it could hardly be said that it was affirmatively and satisfactorily shown that such person did not belong to one of the excluded classes of immigrants. Moreover, it quotes the provision of Section 10 of the act of Mach 3, 1903, that the decision of the board of special inquiry, based on the certificate of the examining medical officer, shall be final as to the rejection of aliens afflicted with a loathsome or with a dangerous contagious disease, or with any mental or physical disability which would bring such aliens within any of the classes excluded from admission to the United States, etc. It says that under the earlier act it has been repeatedly held that the only jurisdictional fact to be established in these cases was the alienage of the immigrant, and that when that appeared the court would not review the decision of the board. The language of the act of 1903 is somewhat different, but it is not thought that by thus modifying it congress intended to provide that before the decision of the board could be accepted as final it must first be made to appear by independent proof as a jurisdictional fact that the rejected alien was actually afflicted with the specified disease. Such an interpretation would make the tenth section meaningless. Wherefore, the court dismissed the writ of habeas corpus.

Hospital Register Not Admissible in Evidence—Privilege.—The Supreme Court of Minnesota holds, in the case of Price vs. the Standard Life and Accident Insurance Company, that a register of patients, kept at a hospital, naming or pretending to name, the disease with which a patient was said to be suffering, is not admissible in evidence to show and establish the nature of the disease. Here the entries in the register in question were made by the superintendent in charge, who was a female physician, in the usual course of business at the hospital, and showed when the patient entered, when he departed therefrom, and the nature of the disease from which he was said to be suffering. This superintendent produced the register, and testified that the entries concerning the patient were made after the physician in charge had observed the case long enough and knew sufficiently about the patient to state the kind of disease, and were wholly based on information received by her from the doctor. The witness had no personal knowledge of the patient, and had no recollection of the case, apart from the record. Therefore, the court says, the entries amounted to nothing more or less than what the superintendent wrote in the register, what the attending physician told or reported to her concerning the patient's illness. To permit these entries to be introduced in evidence was to disregard in a very noticeable manner the rule forbidding the introduction of hearsay testimony, as well as the spirit of the statute which prohibits the examination of a physician as to certain matters without the consent of his patient. The information communicated by the physician in charge to the superintendent of the hospital was acquired by the former while attending the patient, and was necessary to enable him to prescribe or act for him. The physician would not have been allowed to make any such disclosure, and the statutory restriction on him could not be evaded by introducing in evidence testimony of a third party as to what the doctor said about the case. But the entries did not even rise to the dignity of a repetition of what the doctor said to a third party, for the superintendent remembered nothing, except that she made the entries. This testimony should have been excluded. Again, the court says that, although the statute differs somewhat in the several states, the general proposition is that it seals the lips of the physician, and prevents him from divulging in a court of justice information which he has acquired while in the necessary discharge of his professional duty, but it does not absolutely prohibit the examination of an attending physician as a witness. The well-established rule seems to be that a physician may be called on to testify to the simple fact that he has treated or attended a certain person as his patient, and as to the num-

ber of his visits. This doctrine, looking at the question in a logical way, comes very near trespassing on the statute, but the court finds no cases in opposition, and none was cited by counsel.

7 The Surgery of To-day. Alex. Hugh Ferguson.

1. **Typhoid Fever.**—Among the notable points in the analysis of 717 cases observed by McCrae at Montreal were the moderate mortality, 9.2 per cent., the large proportion in which the Widal test was positive, that is, 92.77 per cent., the occurrence of rose spots in 65 per cent. of all cases and the predominance of constipation over diarrhea. The large number of cases of perforation—43, of which 23 were operated on, with 6 recoveries—was also a notable point. The treatment followed was largely that of cold bathing, or cold water, or alcohol spongings. The routine administration of the first bath is, as a rule, at 90 or 85, lowering about 10 degrees the second time and the succeeding baths at 70 or 75. The antipyretic treatment consists of phenacetin, alternating with salol. In most cases a purely liquid diet was given, though semi-solids were allowed in some cases. The author says no rule as to diet will apply to all cases, but that any food that reaches the intestines in any other than a perfectly fluid form is bad.

2. **Spotted Fever (Tick Fever) of the Rocky Mountains.**—Anderson gives his observations on spotted fever of the Rocky mountains. The parasite was discovered by Wilson and Chowning, and their work was described in THE JOURNAL, July 19, 1902, p. 131. Anderson suggests the name tick fever on account of the relation of tick to the disease and the preemption of the term "spotted fever" by other affections. He thinks it resembles typhus fever more than any other disease, and without a blood examination and close bedside observation there might be trouble in the diagnosis in cases of typhus fever occurring in a locality where tick fever prevails. In typhus, however, the long period of incubation, history of cases, the eruption and intensely contagious character and the time of its prevalence, not limited to a short time in the spring, would be important diagnostic points. Until this past season the treatment of tick fever has been purely symptomatic, but since the discovery of the parasite the use of quinin in large doses, preferably hypodermically, has been employed in 5 cases, all of which recovered, while 5 cases that did not have this treatment proved fatal. Anderson hopes that the use of quinin will be followed in future treatment of the disease, and would give it in large doses hypodermically every six hours. He advises its early and continuous use.

3. **Infant Feeding.**—Edsall calls attention to certain biologic peculiarities of milk from different animals and their bearing on the artificial feeding of infants, especially the oxidating ferment in many milks, such as cow's milk, and its absence in human milk, and the diastatic ferment found in human milk and not in cow's milk. He thinks the recent biologic investigations emphasize the dangers of sterilization and indicate that the results of pasteurization are not altogether beneficial since they destroy ferments and, therefore, affect important qualities of milk.

4. **Surgery in Diabetes.**—Noble tabulates 7 cases from his own practice where operations were done in diabetics, with the results. He shows that 6 of them made good recoveries; 1 died in diabetic coma. In the cases that recovered, the general progress was not different from those not the subject of glycosuria. In looking up the literature he is able to add 62 more cases, with 52 recoveries. Seventeen died, 1 of the deaths was from erysipelas, 2 from sepsis, 5 were from causes not stated, and 9 from coma. The chief cause of death after operation in diabetes is from coma. This is the one that it is the least possible to guard against. He advises in all cases preliminary treatment by diet and the administration of codeia and strychnin. He would postpone operation if more than 2 per cent. of sugar was present in a total excretion of three pints per day. After operation, morphin, codeia and strychnia have been prescribed, and salt solution freely administered per rectum and by hypodermoclysis, and the diet strictly regulated. Where the indications for operation were marked he has advised it, at the same time pointing out the risk or the possible occurrence of coma. A review of the literature has not altered his opinion as to the wisdom of this course. When a routine examination of the urine as a preliminary measure to operation is followed, operation on patients suffering from unrecognized diabetes can be avoided. Contraindication to operation is strongest in patients suffering markedly from constitutional symptoms of the disease—poor nutrition, wasting, intense thirst and morbid appetite.

5. **Trichinosis.**—Gould points out the value of blood examination in these diseases and the importance of a large percentage of eosinophiles as a diagnostic point.

8 *The Gastric Contents in Gastroptosis. Thomas R. Brown.
9 *Is Registration and Disinfection a Successful Method of Combatting Pulmonary Consumption? Thomas J. Mays.
10 *The Results of Brain Surgery in Epilepsy and Congenital Mental Defect. William P. Spratling.
11 The Necessity of Special Legislation for the Prevention of the Contamination of Our Water Supply as a Preventive of Typhoid Fever. James Mitchell.
12 *The Treatment of Acute Blennorrhea of Adults. James F. McCaw.
13 *Some Obscure Cases of Eye Strain. F. W. Marlow.

8. **Gastric Contents in Gastroptosis.**—From his analysis of the stomach contents in twenty cases, Brown finds that in simple gastroptosis there is a slight diminution in the amount of free hydrochloric acid in the majority of cases; in cases where the dilatation is slight, the free hydrochloric acid is further reduced, although not markedly so, while in those cases associated with marked dilatation free hydrochloric acid is usually entirely absent. These facts would suggest that gastroptosis *per se* leads to a very slight diminution of free hydrochloric acid, and that it is the subsequent dilatation which so often complicates gastroptosis that leads to marked dilatation, the diminution being apparently more marked the greater the associated dilatation.

9. **Tuberculosis.**—Mays analyzes the death records from pneumonia and tuberculosis in a number of cities and claims to find that the combating of tuberculosis by disinfection, registration, etc., seems to increase the pneumonia mortality, and that in a number of the localities where these are practiced there has been an increase in phthisis during the last five years.

10. **Brain Surgery in Epilepsy and Idiocy.**—Spratling's paper is concluded with an analysis of the results of surgery from the literature and his own observations. He thinks the statistics show that if epilepsy is general and of some years' duration we need not look for a cure, though in selected cases operation may ameliorate the symptoms, but most frequently only temporarily. If the epilepsy is unessential, reflex, rudimentary in type, or of short duration, and the operation removes the cause early enough, we may expect the convulsions to cease in many cases, provided the patient is free from the vices of heredity that are beyond the reach of the surgeon. He does not find a single case of congenital mental defect in which a normal mental status was established through surgical intervention. There are many reports of cases benefited by surgery, the degree not being given, making it diffi-

cult to judge of its value. The fact that operations for this purpose have gone into disuse is the strongest argument against their utility. They may have a limited value, but not what was at one time expected.

12. **Acute Blennorrhea of Adults.**—McCaw advises prophylaxis by extreme avoidance of any possible way of infection and the cautioning of every woman with vaginal discharge and every man with gonorrhea as to the dangers to the eyes from such discharges and the importance of thorough cleanliness. He makes the assertion that cocain should never be used in eye diseases, though a few exceptions are admitted. He would prohibit bandaging and poulticing of the eyes. The first thing indicated is the use of cold compresses, except where the conjunctiva looks harsh and is covered with a tenacious grayish exudate, in which case hot applications are preferable. Cold should be kept up regularly day and night from twenty-four to thirty-six hours. During the second stage, where there is free purulent discharge, the important part of the treatment is frequent and thorough cleansing of the eye. He would use here one-half saturated solution of boric acid for this purpose. As soon as free purulent secretion is established and the conjunctiva is in a succulent condition, it should be brushed twice daily with a 2 per cent. silver nitrate solution as long as the free discharge continues. On the first indication of corneal infiltration or ulceration iced compresses should be discontinued and hot applications substituted. He insists on attention to the general vital condition of the patient.

13. **Eye Strain.**—Three cases are reported by Marlow, the consideration of which, he says, indicates the following points:

The most careful investigation and the apparently accurate correction of all the discoverable errors may completely fail to relieve the symptoms; may, in fact, aggravate them, and yet the symptoms may still be due to eye strain. Indeed, the fact that glasses which are apparently correct aggravate the symptoms is, I believe, in most cases evidence that the latter do arise from eye strain, and that a latent error is present, usually an error in the muscle balance. In all the cases described the possibility of the existence of the kind of error which was finally found to be present was fully appreciated from the first. In the second place, I believe that lapse of time is a very important factor in the elucidation of the true nature of these cases. The action of the accommodation in neutralizing refractive errors is so automatic and persistent that all efforts to annul it sometimes fail to be completely effective, even atropin and other powerful cycloplegics failing to bring about a complete relaxation. The natural relaxation due to advancing years often reveals a hitherto latent error. Similarly the instinctive tendency to see single and not double causes the extrinsic muscles to contract so as to maintain a parallelism of the visual lines. This contraction is so constantly maintained that the muscles get into a condition of tonic spasm which is extremely persistent. Just as we have a spasm of the accommodation in cases of hyperopia and astigmatism in the interest of clear vision, so we have a spasm of the extrinsic muscles in the interest of single vision, and the latter is far more difficult to demonstrate than the former. It is surprising what high degrees of error may remain latent year after year and produce a train of symptoms absolutely intractable to treatment until the manifestation and correction of these errors has occurred. I have seen some cases which have inclined me to think that not only is lapse of time the only thing which will reveal the true nature of the ocular conditions, but that old age itself is reached in some cases before the true condition becomes manifest.

18 Post-graduate Work in Budapest. Willard J. Stone.
19 A Case of Venereal Warts. A. P. Stoner.
20 Circumcision in Infancy. William B. Harlow.

14. **Conservatism in Medicine and Surgery.**—Robinson's article is a plea for greater conservatism in medicine as well as surgery. He notices particularly in reference to the former the change of views regarding the cold bath in hyperthermic conditions, the over-use of arsenic, quinin, morphin, etc., the tendency to employ too many drugs and the need of attention to hygiene as against too indiscriminate drugging.

15. **Epidural Injections for Enuresis.**—Valentine and Townsend give the results of epidural injections according to the Cathelin method by injecting normal salt solution into the lower extremity of the spinal canal at the tip of the sacrum under antiseptic precautions, and describe the technic. The patient is placed on one side or the other and the lower sacral opening is then a little above the line between the nates, as he shows by a figure. When epidural injections are made for disturbance of urination the authors say it is well to place the patient in a sort of Sims position, the knees drawn as tightly as possible towards the chest and the legs flexed. The fingers are passed down over the sacral spinous processes until the last perceptible one is felt under the finger tips of the left index and middle fingers. These are then slightly separated and pushed downward until each of them presses an osseous tubercle. The skin is stretched over these tubercles, and between them is the point of puncture. The needle is held at an angle of about 40 degrees to the sacral curve and thrust through the tensely stretched skin, then depressed about 20 degrees and the middle finger raised from the skin while the index is pressed on the point of puncture to steady the needle and the tissues. In this position the needle is cautiously pushed up into the sacral canal; and if no gross abnormality exists and the method is sedulously followed, the needle can be entirely inserted without touching the periosteum of any part of the sacral canal. (See cuts on page 888 of THE JOURNAL.) An injection is slowly made of about nine-tenths of the contents. The after-treatment is simply wiping dry and covering the site of puncture with a little collodion. The conclusions which seem warranted are given by the authors as follows:

1. Epidural injections with decinormal salt solution offer the most promising results in abnormalities of urination due to faulty vesical innervation.
2. Incontinence of urine, enuresis, excessive frequency of urination (unless due to other pathologic conditions) can at least be ameliorated by epidural injections.
3. Cautiously performed, epidural injections are in no wise dangerous to the patient.
4. Epidural injections are no more painful than any hypodermatic injection with a mild solution.
5. Epidural injections can be performed by anyone who follows the technic outlined and is alert to those anatomic variations which are so frequent in the region.
6. The immediate effects of epidural injections are very rarely even disagreeable.

16. **Nitrous Oxid Anesthesia.**—Meeker advocates the use of nitrous oxid anesthesia as the safest method in minor surgical operations and as a preliminary to ether anesthesia.

17. **The Pedicle in Ovariotomy.**—Dunning reviews the various methods and gives the ordinary methods of treatment of the pedicle. He calls attention particularly to the dangers of intestinal adhesions to the stump in both ovariotomy and salpingo-oöphorectomy. Of a large number of methods brought forward to do away with the stump in the latter operation, none has seemed entirely satisfactory. The method he occasionally employs comes near meeting the requirements, but has an element of danger in inexperienced hands. This consists in boldly cutting across the fallopian tube at the uterine horn, then severing the attachment of the mesosalpinx from the under surface of the fallopian tube, cutting free the ovary from its attachment to the broad ligament and uterus, tying all bleeding vessels, and with a whip-row stitch closing in all raw surfaces. One unfortunate experience with hemorrhage led him to see the danger of such free cutting without more extensive ligation of the blood vessels. In some very vascular patients he has sometimes ligated the ovarian artery near the pelvic wall to avoid this. For several reasons the stump method is the preferable one if a sufficiently long pedicle can be found, but he points out the possible dangers and difficulties in covering the stumps. For many years he has used catgut alone for ligation, and has had no reason to regret the selection of this material. He never leaves the pedicle without having ligated each artery in it.

26 *The Pathology and Treatment of Tardy Post-operative Intestinal Obstruction, with a Report of Cases. Ellsworth Eliot, Jr.

21. **Typhoid Fever.**—Butler believes in the milk diet, though varied with buttermilk, koumyss, oyster and clam soup, etc. The stools should be inspected for undigested curds and the milk be either stopped or diluted one-half with water, plain or mineral, or peptonized. If the patient is accustomed to tea or coffee, he would not cut them off entirely, but allow them once daily. In all cases lemonade, orange juice and grape juice are not only allowed, but encouraged, unless there is a troublesome diarrhea. Mutton, beef and chicken broths, bouillon, consommé or other clear soups are given in moderation unless the bowels are moving too freely. He also uses the white of an egg or the whole egg beaten up and employed a little sparingly. Plain ice cream, water ices and jellies are, as a rule, unobjectionable. Lactose is a valuable force producer and may be given in some cases, one, two or more ounces daily, dissolved in milk or water. With the above dietary the variety is usually sufficient, which is a matter of some importance unless the patient is delirious. We often prescribe more food than can be digested, and a persistent feeling of gastric discomfort, nausea, tympanites, etc., should be watched for. Water should be given as regularly as food. He would not take up solid food until three days or more after defervescence, and then use soft food only. He remarks that the cold bath is less used than formerly. Cold is not merely demanded for fever, but also for its stimulating and tonic effects, and he recommends the following methods for the application of cold: First, a cold-mitten rub, repeated at intervals of three to six hours when the fever reaches 102.5, then the towel bath of Baruch, and ice rub, which is still more vigorous in its action and requires some discretion in its use. The cold-mitten rub is usually sufficient for most cases. During the intervals between cold rubbings a wet compress to the abdomen is advised by some authorities, though he has seldom employed it. He advises measures of prophylaxis, such as disinfection of the patient's hands, cleansing of the nails, etc., and as regards medicinal treatment, many cases do best with little or no medication, but he thinks well of intestinal antiseptics and an initial dose of calomel, and remedies for intestinal hemorrhage, such as calcium chlorid and gelatin and powdered suprarenal as an arterial constrictor. A pint or more of a 10 per cent. solution of gelatin may be given in the twenty-four hours; 20 to 30 grains of calcium chlorid every two to four hours, and 5 or more grains of the desiccated suprarenal every four hours up to half a dram in twenty-four hours. He prefers these as a routine measure to the opium, ergot and lead of former treatment. To quiet the restlessness and excitement moderate doses of opium or its alkaloids are advisable in cases of hemorrhage.

22. **Blood Cultures in Typhoid.**—Hektoen reports a case and emphasizes the point that the practically constant presence of typhoid bacilli in the blood in the early stages during the height and at the beginning of relapses of typhoid makes it possible by the use of proper culture methods to settle the diagnosis of typhoid in special cases like those reported. This is also true in cases of paratyphoid fever.

23. **Typhoid Fever in Infancy and Childhood.**—Griffith points out the peculiar characters of typhoid in infancy and its greater frequency than has been generally estimated. The chief characteristics are the less typical onset and the tendency of nervous symptoms to overbalance intestinal ones. The average duration may be stated as from fourteen to twenty-one days, although often a little longer. The diagnosis is difficult and the value of the Widal test is inestimable. He emphasizes the importance of some complications and sequelæ. Relapses seem to be about as frequent as in adults. The prognosis is on the whole good. As for treatment, he does not advise cold baths. His custom is to apply sponging first, and if this is not sufficient a graduated bath of 90 degrees lowered down to 80 F. In many instances he has had good results with the abdominal ice bag. In some cases a warm tub bath of 95 to 100 is productive of good results. Sponging sometimes has a bad effect and it is a very questionable procedure in case the child is crying or struggling. Children develop a high temperature readily and tolerate it well, therefore the temperature can be let alone in many cases.

24. **The Treatment of Typhoid Fever.**—Baker believes in a more liberal diet in typhoid than some authors. He would allow more or less soft foods, but avoid any harsh materials. Mushy masses that do not over-distend the abdomen may do good by wiping off mucus and helping to carry off the discharges. For medication he thinks a cleaning out by the use of calomel useful; when the fever is high phenacetin, codein, salol and quinin in combination, and carbolic acid and tincture of iodin, 1 minim of the former, 2 of the latter in water every four hours in the daytime for its antiseptic effect. In case the carbolic acid is disagreeable any other good antiseptic will probably do. He notes the favorable reports as regards acetozone, but has not yet tried it. Hydrotherapy is used in all the ways he knows of, and he insists on the importance of good nursing. He tabulates 31 cases treated after this plan with good results, which he thinks support his view.

25. **Gallstones.**—Herter discusses the origin of gallstones, the existence of biliary stagnation producing infection and cholecystitis and the mode of action of the bacteria, decomposition of the bile and the influence of biliary reactions, concentration, foreign bodies and the agglutinative action of bacteria. He thinks gallstones may form within a comparatively short time, in three to six months under favorable conditions, and that bacteria may enter the gall bladder from the intestinal canal by the normal routes or from bacterial foci which discharge into the general circulation, and by the passage of bacteria from the intestine to the portal circulation, which he thinks is possible in spite of the negative results of Carmichael. The question whether constitutional influences can produce gallstones is also noted, and the need of future study on this point is mentioned. He reports experiments on the excessive feeding of fat as having a bearing on the production of biliary concretions, but the results are more suggestive than complete. Arteriosclerosis is possibly coincident, but not necessarily a cause. He thinks the future treatment of gallstones will be chiefly in the way of favoring the subsidence of cholecystitis.

26. **Post-Operative Intestinal Obstruction.**—The importance of avoiding adhesions in laparotomy cases liable to produce post-operative obstruction is emphasized by Eliot, who describes the symptoms and points out the dangers of leaving raw surfaces and of drainage. The immediate post-operative treatment for the prophylaxis of these adhesions is the establishing as early as possible of exaggerated peristalsis. During the first twenty-four hours he would use rectal enemata and warm saline solution, with or without turpentine, and in cases of persistent vomiting he would use lavage. As soon as the nausea and vomiting subside, small doses of calomel and salts should be administered and movements favored by high turpentine injections. The formation of adhesions is still further probably decreased by frequent changes in posture and the raising or lowering of the head, the foot or sides of the bed. These are not routine methods in every case, but only when there has been an extensive or infectious peritonitis or after operations involving suture of intestinal loops or operations for the relief of obstruction due to bands. The actual treatment of the obstruction itself does not differ from the treatment of obstruction from any cause. Early laparotomy, the ligation and removal of constricting bands, the disentanglement of adherent intestine, with resection if necessary, the closure of the abdomen with or without drainage and the prevention if possible of subsequent adhesions is the general routine treatment. Several cases are reported in detail.

29 *Tuberculosis of the Spine. A Statistical Study of the Cases in the Orthopedic Department of the Carney Hospital. Joel E. Goldthwait.
30 *A Note on the Association of a Rise in Systolic Blood Pressure with the Onset of Perforative Peritonitis in Typhoid Fever. John Bradford Briggs.

29. **Tuberculosis of the Spine.**—Goldthwait analyzes 108 cases of Pott's disease in the out-patients of the orthopedic

department of the Carney Hospital prior to 1902. Sixty-two of these reported more or less regularly for treatment; 41 of the latter were under 30 years of age, and in 21 of the cases the disease had existed for from six to twenty years before applying for treatment. In 20 cases there was abscess. Of this number 8 died and 4 are at present in poor condition. In 11 cases there was paraplegia, and of this number 2 died. Of the 62 cases 11 died. In nearly all the cases death was due to local infection or to its extension to some other part of the body, the average time between the onset of the disease and the time of death being four years. He calls attention to the fact that these cases were hospital ones, living under poor hygienic conditions. At the last report 20 patients were entirely free from symptoms, and in 18 others there has been great improvement.

30. **Blood Pressure and Typhoid Perforation.**—For two years Briggs has noticed a sharp rise in the systolic blood pressure, as measured by a modified Riva-Rocci apparatus, occurring in patients undergoing laparotomy and produced by mechanical irritation of the peritoneum. Dr. Harvey Cushing suggested that a similar rise in the blood pressure could possibly be produced by intestinal perforation and might be of value in the early recognition of this accident. From Briggs' own observation and those of Dr. Cook he notices that patients suffering from acute general or rapidly spreading peritonitis, of whatever origin, uniformly showed a state of hypertension of the pulse, and similar observations have been made and reported by Crile. During the past year they kept close watch on the blood pressure in the typhoid patients in Dr. Osler's service in the Johns Hopkins Hospital, and in 2 patients out of a large number abdominal symptoms justifying exploratory laparotomy were observed and the condition of the blood pressure in each was of interest. These 2 cases are briefly reported. In one perforations were found; in the other the symptoms suggested perforation, but there was no rise of blood pressure to speak of, and Briggs considered therefore that no perforation had occurred, but the abdomen was opened and the intestines carefully examined and no perforation found. He thinks it seems certain that patients with a general or rapidly spreading peritonitis have constantly, or at least in early periods, an abnormally high blood pressure. That in perforative peritonitis a sharp rise in blood pressure may precede the onset of other symptoms. That in doubtful cases like his second one, where perforation is suspected, and the general previous blood pressure is known, the course of blood pressure after the onset of grave symptoms should receive consideration in determining the propriety of operation.

34. **Deformity at the Hip.**—Gibney deprecates the use of force in the correction of hip deformities resulting from disease, and rather favors the use of subcutaneous osteotomy in these cases. He holds that the corrected position must be maintained for many months under a closely fitting plaster-of-paris bandage followed by a closely fitting splint for several months more. He would prefer to have the ankylosed limb straight rather than slightly flexed, as there is less danger of developing trouble later with this than with the flexed limb, and walking is less interfered with.

35. **Subtrochanteric Osteotomy.**—Bradford claims that the operation of subtrochanteric osteotomy for the correction of deformity following hip disease can be done in adults without fear of non-union, or even in middle life, and that the danger of relapse is greater when the operation is done in childhood or rapidly growing years. The period of convalescence and disability, however, is comparatively longer when the operation is begun later in life, but he recommends deferring the operation when possible until the period of rapid growth is passed.

37. **Genu Varum and Genu Valgum.**—In these conditions Blanchard believes in correction by osteoclasis or osteotomy and that epiphysiotomy is hardly worthy of consideration. Osteotomy has some slight dangers from which osteoclasis is free, and the long period required for bone union and recovery would condemn it when osteoclasis is available.

38.—This article appeared elsewhere. See THE JOURNAL of July 18, ¶6, p. 204.

39. **Osteotomoclasis.**—This new operation is suggested by Hopkins in cases where simple osteotomy is inappropriate. It consists in a combination of partial osteotomy and osteoclasis. Partial section, he says, seems to be a rational preliminary step to osteoclasis in certain cases. He would use the combined operation in cases suitable for osteotomy, producing the simple instead of compound fracture by the method, osteoclasis being performed after the skin wound has entirely healed.

43. **Carcinoma of the Breast.**—Pilcher gives the results of 50 cases which have been under his care in the Seney Methodist Hospital from 1888 to 1900. In 7 of them the disease had extended beyond the possibility of entire removal, and in 1 of these, in which a portion of the rib was removed, pneumonia developed which proved fatal in three days. This is the only fatality attributed to operation in the whole series. He classifies his operations according to their extent. In 2 cases ablation was complete to the apex of the axilla, without removal of any pectoral muscle. One of these remained well for six years, when intrathoracic disease developed which proved fatal. The second underwent a second operation eighteen months later, and remained well for five years, when the same disease appeared in the other breast. This second breast was removed, together with the contents of the axilla and the pectoralis major, but cancer of the liver appeared three years later and death occurred ten years after the first operation. In 11 cases ablation was complete to the apex of the axilla with removal of the pectoralis major muscle. Three cases are still well at the end of eight years or more. One died of cerebral apoplexy one year after operation without recurrence of the disease. Another one has remained well for

six years, but has had slowly advancing carcinoma since, and is now, nine years after operation, still living, but in feeble health. Three cases died from recurrence within periods of from a few months to two years. The eighth case was the one already mentioned in the preceding class. One remained well for a year and has since been lost sight of. In the third class, where both pectoralis muscles were removed, 2 are well for three years or more after the operation; one is living five and a half years later, but has a slowly advancing recurrence. Another is still living three years after operation without external recurrence, but with evidence of liver carcinoma; 6 died at periods varying from 12 months to five and a half years after the operation. In 18 cases operation was still more extensive; one or both pectoralis muscles were removed and the glands in the subclavicular region. Only 2 of these patients have remained well at six and four and a half years respectively, though one of them has beginning enlargement which suggests a recurrent disease in the ribs. The others are all dead, mainly from intrathoracic metastases. Pilcher considers that his experience has emphasized the fact that nothing is more illusive than the apparent local extent of carcinoma processes. The size of the local growth is no positive index to the number and distance of outlying deposits. He insists that practically every case of carcinoma of the breast when it has reached that degree of development at which a probable tumor is formed is already in an advanced stage and metastatic processes have, as a rule, already begun to be formed. Nevertheless, experience warrants the statement that surgery can promise a large percentage of absolute cures if employed as soon as the presence of the disease is determined.

44.—This article appeared elsewhere. See THE JOURNAL of September 5, title 91, p. 637.

51. **Fracture of the Vertebrae.**—The following are the conclusion of Owens' paper, which includes a report of cases and a discussion of the localization:

1. Laminectomy is superior to a simple reduction of the deformity, since, in fractures of the arches, reduction has no certain effect on isolated fragments, and reduction alone has hastened death. 2. Reduction may be more rational when effected through the open wound of laminectomy. 3. Simple reduction is useless where there are clots or adhesions sufficient in themselves to account for the spinal disturbance. 4. In cases of cervical luxation without fracture, simple reduction has given good results. 5. It is possible to still further improve the prognosis of reduction in simple cervical luxations by making the reduction with the arches exposed and employing silver wire suture of the processes to prevent relapse. In consideration of the distressing prognosis in lesions of the cervical region, an operation appears strongly indicated. Degeneration is observed wherever the narrowing factor is not removed. The treatment of vertebral fractures without operation offers a chance of success only where there exists little or no disturbance of the spinal cord, such as paralysis of a single group of muscles, one-sided paralysis or partial disturbances of sensibility, etc. In all cases where the usual assemblage of symptoms indicates a severe alteration of the cord, only prompt operations directly afford the best chances of securing improvement or cure.

52. **Dislocation of the Clavicle.**—Sheldon discusses the diagnosis of the condition and the conclusion which he reaches is that operation is advisable in every case where there is complete rupture of the coracoclavicular ligaments. There is only one case reported with symptoms pointing to complete rupture that terminated favorably without operation. The most approved method of procedure is exposure of the joint by incision; drilling the clavicle and acromion; passing and tying two absorbable sutures; approximating ligaments and fascia with fine catgut and suturing the skin wound with silkworm gut. He does not believe in the use of silver wire for suturing the bone, holding that absorbable sutures are better.

53. **Method of Retaining Fractured Ends in Position.**—Johnson suggests the following method as valuable in retaining the ends of fractured bones in position while applying plaster casts. His method is to take two or three strips of bandage, smear them with vaselin and apply one strip around the humerus for example, above the fracture, one just over the seat of fracture and the third on the forearm just below the elbow, these being applied under anesthesia. These strips are given to two assistants, and under the surgeon's direction the upper one may be pulled back, the lower one down, and the middle one tightened to keep the bones from tilting up at that point after they have been approximated. Then he would put on a loose flannel roller from the hand to the axilla, then a sufficiency of raw cotton, and finally plaster rollers, ignoring the traction strips and putting the bandages, cotton, etc., around or over them as if they did not exist, the assistants keeping up their pull in the lines indicated. In five minutes the plaster has hardened and the bones are fixed in the position desired. These tense straps which the assistants have been pulling on might produce strangulation if left, but as they are covered with vaselin by letting go one end there is no difficulty in pulling them out from beneath the plaster, leaving a small hole, which can be easily filled up to make it neat. As soon as they are removed split the plaster down in front and bring it together loosely with the adhesive strips so as to make room for the tension from swelling of the arm. He has repeatedly used this method. He frequently keeps the splints on for the whole treatment with satisfactory results.

63 *Pertussis as an Etiologic Factor in Uterine Displacements. Walter B. Jennings.

63. **Pertussis and Uterine Displacements.**—Jennings considers the anatomy of the uterine supports and the effects of paroxysms of pertussis on the body. He reports a case in a young woman of the athletic type who while perfectly well up to 20 years of age developed a third degree backward displacement of the uterus after an attack of pertussis. So far as it is possible to draw conclusions from the case they should be as follows:

1. Pertussis may be an exciting cause of backward displacement of the uterus. 2. The effect of the paroxysm would be to loosen the uterine ligaments, and muscular contraction of the abdominal muscle, together with a downward pressure of the diaphragm, would tend to force the uterus backward. 3. As a result of venous stasis of all the organs in the body, there would be a tendency to an increase in the weight of the uterus, and this would tend to a backward displacement.

65. **Bacteriology of the Blood.**—Houghton reviews the literature and reports experiments and investigations, describing his methods. He concludes that the approximately normal blood contains pyogenic bacteria in a greater or less degree, their manifestation depending on other conditions. Bacteriologic examination of the blood is of little or no value in the diagnosis or prognosis or as indicating treatment. When positive results are obtained there is no assurance that the infective agent found is that which is responsible for the primary infection; or that it is not a cryptogenetic infection; or that a second examination will likewise prove positive; or where only one infective agent is found that this is the only one present; or where two are found that both are concerned in the primary infection. In cases where the results are negative we have no reason to believe that the blood is free from bacteria, or that another examination will likewise prove negative.

72 The Mysteries of Plague, Past and Present. C. N. Ellinwood.

69.—This article was noticed editorially in THE JOURNAL of October 3, p. 856.

70. **The Liver Reflex.**—This is described by Abrams as elicited by irritating the skin contiguous to the lower liver border, either electrically or by a spray of ether, or scratching of the skin by the finger nail or the blunt end of a pencil. The lower liver border can be observed after this maneuver

to recede one-half inch or more, depending on the degree of irritation. The retraction is dependent entirely on the contractility of the organ itself and the muscle fibers in its fibrous coat. The size of the liver can also be influenced by what he has called the cardio-splanchnic phenomenon. He enters at length into the directions for percussion of the liver to elicit this reflex, and the difficulties due to the thinness of the border and the hollow organs bounding it. The patient must be instructed to take no inspiration while the body is inclined backward and light percussion is executed, otherwise there will be a downward respiratory dislocation of the liver. In practicing percussion the finger receiving the percussion blow must be firmly imbedded in the abdominal wall, otherwise it will not be directly transmitted to the liver. He points out that this reflex is more pronounced in cases of active or passive congestion. In case the liver enlargement is due to a connective tissue hyperplasia, it will be absent or only slightly present. The prognosis and treatment may be affected in both ways. The sinusoidal current is really the best irritant for eliciting the reflex.

75. Fowler's Position.—Knott advocates the use of Fowler's position which, instead of draining the immune portion of the peritoneal cavity on to the upper and sensitive portion, reverses the process, and he wonders that the method was not earlier recommended in cases of septic peritonitis. He reports five cases in which it was successfully used. The theoretic assumption that in debilitated patients the elevated head position might be pernicious is not verified in his cases, as there has been no cardiac embarrassment or other symptoms referable to the position, and patients have declared that they were more comfortable with the head elevated than with it down. He has noticed also that flatus has been passed earlier and more freely and there is no increased tendency to phlebitis. The position is maintained for twenty-four hours unless some special reason for continuing it was present. The head of the bed should be raised from twenty-four to thirty inches from the floor, and an elevation of thirty inches is much better than one of twelve.

82. Acute Myelogenic Leukemia.—Billings and Capps report a case which they refer to this type and discuss the literature, reviewing eight reported cases which seem to be unmistakable. From these published cases as a basis they sum up the blood picture of acute myelogenic leukemia as follows:

1. Anemia, progressive and severe. 2. A large increase of white blood corpuscles (16,000 to 540,000). 3. A large proportion of the white cells (25 to 96 per cent.) made up of myelocytes, large mononuclear cells of the same size, and faintly granular large mononuclear cells (transitional cells). 4. Eosinophiles, mast cells and nucleated red corpuscles may be absent or present in varying numbers.

84. Pneumonia.—The early symptoms of lobar pneumonia are reviewed by Conner and Dodge from observations of a series of 392 cases. They notice particularly the enfeeblement of respiration among the earliest symptoms, and attribute its cause to the greatly restricted expansion of the enlarged and stiffened part of the lung. The length of time in which the area of feeble breathing was observed before the appearance of bronchial breathing varied from one day or less to five days. Harsh or exaggerated breathing occurred in 8 out of 124 cases of beginning pneumonia, which they take to signify deep-seated involvement of the structure. Râles were heard in 110 cases before the advent of bronchial breathing; about 50 per cent. were described as crepitant, most of the remainder as subcrepitant. Their experience corresponds with that of Skoda, that crepitant râles are by no means always observed. They place the physical signs of beginning pneumonia in the order of relative frequency, as: 1. A circumscribed area of feeble, indistinct breathing as compared with the breathing at the corresponding point on the other side. 2. A circumscribed area of impaired resonance, with or without a tympanic quality, obtained under similar precautions. 3. The crepitant râle. 4. A slight increase in the intensity and clearness of the vocal resonance. Bronchial breathing and bronchophony make their appearance coexistent with and indicative of complete hepatization of a larger or smaller portion of the lung tissue. In almost all the cases observed the bronchial quality first appeared during expiration. In most cases the sounds were faint, soft and of very low pitch, usually existing for about twelve hours, but occasionally for longer periods. Concerning the signs of percussion in the second stage, they find that when the consolidation affects the right lower lobe posteriorly, there is found very commonly over the middle lobe in front a strikingly deep, hyperresonant note of more or less distinctive tympanic value. This is heard in the circumscribed area in the fourth and fifth spaces within the nipple line. It has been frequently possible by it to predict the position of the consolidation before the back had been examined. The bronchial breathing usually appeared from the third to the fifth day, rarely in the first day. In four cases of undoubted pneumonia neither bronchial breathing nor bronchophony could be found at any time. The gradation of change from bronchial to normal vesicular breathing should fall in inverse order to that observed in consolidation. The relation of the disappearance of bronchial breathing to defervescence is mentioned. This occurred at various periods from before defervescence until six or seven days after, or more. They notice here in this respect three distinct groups: 1. Those in which the signs of consolidation appear one, two or three days before the temperature fall. 2. Those cases, by far the most numerous, in which beginning resolution coincided with the fall in temperature or followed it in a day or two, and in which resolution progressed rapidly and was complete within a few days or more. 3. Those cases in which with defervescence signs of complete consolidation persisted for several days or longer before the appearance of beginning resolution. There were 30 in which the signs of consolidation lasted for more than two weeks, and in one where there were no signs of consolidation for sixty days. The question of central pneumonia is discussed. The authors think the practice of applying this term to cases where signs of consolidation are late in appearing is unwarranted, and that this stage of diminished breathing in pneumonia corresponds with incomplete consolidation or engorgement limited to the interior of the lobe. They hold that true cases of central pneumonia are probably much rarer than popularly supposed. They have noticed a progressive rise and fall in the pitch of bronchial breathing and consider it related rather to the degree of consolidation than to the proximity of the consolidation to the surface.

87. **Relations Between Adenocarcinoma and Scirrhus.**—Stewart discusses the question of this relation and reports cases illustrating his views. His summary is as follows:

1. The term atrophic scirrhus is worthy of retention as describing an important clinical entity. 2. It is extremely doubtful whether such cases are benefited by operation. 3. Certain adenocarcinomata of the breast have the clinical history of the atrophic scirrhus. 4. It seems probable that if more of these tumors were studied histologically they might prove to have an adenomatous element to justify their comparative benignancy.

89. **The "Essential" Dropsies of Childhood.**—Fairbanks describes the angioneurotic edemas of childhood, reporting personal observations and reviewing the literature. He adopts the neurotic theory, holding that no one bodily cause can be regarded as essential unless it is exposure to cold. He does not recognize the close relation of the condition to urticaria, holding that the occurrence of the latter is secondary.

93. **Syphilis as a Cause of Chorea.**—Mettler reports cases and discusses syphilis as a cause. He formulates his conclusions thus:

1. Syphilis in rare instances is a cause of chorea, and should always be thought of as a possibility in the examination of every case. 2. Chorea may be the result of acquired or hereditary syphilis. 3. Most of the cases of syphilitic chorea are unilateral; belong to the prehemiplegic or posthemiplegic type of the disease; may or may not be associated with other signs of an irritative lesion; are not infrequently developed in hereditary syphilitics, and are to be attributed probably to a functional disturbance of an irritative sort in the cortical and ganglionic motor cells. 4. The existence and recognition of these two forms of syphilitic chorea—the focal and the generalized—support the inference that all forms of chorea are but the expression of one or more of a multiplicity of possible factors which may disturb the functional activity of the upper motor neurons, these factors being all the way from a gross lesion down to a molecular or chemical change not demonstrable with our present means of investigation. This conclusion leads to the further conclusion that chorea is not a disease, but a mere symptom. 5. Syphilis, when determined as the cause of a case of chorea, should lead to the prompt and thorough treatment of the case as one of syphilis and not chorea.

95. **The Writing Center.**—The existence of a separate center for writing is maintained by Gordinier, who reports a case which seems to prove the existence of a separate and distinct cortical center for writing, having the same relation to writing movements as the motor speech center has to speech movements. This center is located at the base of the second left frontal convolution for the right-handed. Destruction of this center produces pure motor agraphia without aphasia or paralysis of either arm. The case is illustrated, showing the lesion in the place indicated, and seems to be fairly conclusive as far as a single case can be.

102 The Treatment of Chronic Diseases by Physical Therapeutics, Through the Sympathetic Nervous System. Albert C. Geyser.

99. **Rheumatoid Arthritis.**—Bishop holds that this is a disease of the nervous system. The treatment which he would use for the earlier cases is the application of a surging high potential alternating current on each side of the vertebræ for five or six times. After this he treats the liver, kidney region, spleen and lymphatic vessels and glands as well as the joints. This alternating surging current produces an efficient and very deeply penetrating spark, which is practically painless. When treatment has been begun early enough decided improvement has taken place. When it cures it is gradual and progressive, but may require months. He insists on the importance of early diagnosis. Trophic changes are first in the nerve centers, second in the nerves, and lastly in the muscles and joints.

104. **Tuberculous Peritonitis.**—Ochsner has tabulated 32 cases of tuberculous peritonitis treated in one hospital, showing the immediate and late results. Since then he has operated on 8 cases, and from all these, though the number is small, he thinks the following conclusions concerning the toilet of the peritoneum in these cases are warranted:

1. In the absence of ascitic fluid in the peritoneal cavity, the diseased tissues may be removed with safety if the section is made entirely in healthy tissue. 2. In the presence of ascitic fluid the latter should be evacuated and the abdominal cavity drained. 3. Great care should be exercised in making the intra-abdominal manipulations and examination not to cause any abrasions. 4. Adhesions should not be disturbed. 5. The less the tissues are manipulated, the better will be the results. 6. Manipulations of the infected pelvic organs—uterus, ovaries, fallopian tubes—is less harmful than manipulations of the infected intestines.

108. **Tonsillar Hemorrhage.**—The prevalent opinion that tonsillar hemorrhage is seldom dangerous is refuted by Ryan, who reports cases where very serious trouble and danger followed operation. He reviews the statements of others and shows that it is clear that alarming cases do sometimes occur, though as yet no fatal cases have been recorded. The dense fibrous tonsil of the young adult seems to produce the most dangerous symptoms. He would put the various methods in the following order in the order of their danger: 1. Removal by bistoury, an almost obsolete method. 2. Removal by the tonsillotome, which elevates the tonsil. 3. Removal by the flat tonsillotome as done by McKenzie. 4. Removal by the galvanocautery snare. 5. Removal by the cold snare. 6. Dissection or tonsillectomy by the galvanocautery knife, requiring several sittings. He would hesitate now about removing by amputation the fibrous tonsil of people over 25 years of age, and especially if it is densely fibrous.

Titles marked with an asterisk (*) are abstracted below. Clinical lectures, single case reports and trials of new drugs and artificial foods are omitted unless of exceptional general interest.

British Medical Journal, London.
September 19.

1 *A Discussion on Disposal of Excreta in the Tropics. W. J. Simpson and others.
2 *Sprue: Primary and Secondary. P. W. Bassett-Smith.
3 Malaria: The Mode of Entry of the Spore Into the Red Corpuscle. Cuthbert Christy.
4 *Discussion on Trypanosomiasis. Patrick Manson and others.
5 Five Cases of Abscess of the Liver. P. W. Bassett-Smith.
6 Liver Abscess, with Ten Cases. James Cantlie.
7 *The Pathology of Acute Rheumatism and Allied Conditions. E. W. A. Walker and J. Henry Ryffel.

1. **Disposal of Excreta in the Tropics.**—Simpson advocates the use of water-tight and isolated cesspools where surface contamination is impossible and subsequently, after fermentation, the employment of the excreta for fertilization and gives his reasons. In the early stages the excreta are protected from flies, and in the feces of vegetable eaters is a large amount of undigested vegetable matter and cellulose which are more thoroughly broken up by anaërobic than by aërobic organisms.

In the subsequent discussion Rogers gives the results of experiments as to the effect of the septic tank on the life of various pathogenic organisms and, as far as his results go, they show that the septic tank process is inimical to most of the pathogenic organisms, including the cholera bacillus, staphylococcus, streptococcus, typhoid bacillus, Malta fever germ, and excepting only the anthrax bacillus. On the other hand even small quantities of effluent from the tanks showed both the *Bacillus enteritidis sporogenes* and streptococci, and its subsequent discharge through filters and then over a small piece of land with subsoil drainage failed to free it from these organisms and from a large number of colon bacilli. It would not be safe, therefore, to allow the water to contaminate water used for drinking.

2. **Sprue.**—Bassett-Smith disagrees with the American surgeons in not considering sprue a sequel of dysentery in all cases. He reports cases with blood findings and notices particularly the characteristic anemia which is close to that of pernicious anemia except that the hemoglobin value of the cells is also reduced and megaloblasts are not present. The cardinal points in coming to a diagnosis are irregular and chronic diarrhea with dyspepsia causing flatulent distension of the abdomen, the occurrence of fermenting offensive stools which in chronic cases become pasty, clay-colored and very abundant, progressive emaciation, extreme secondary anemia, and changes in the buccal mucous membrane with or without the production of an aphthous condition.

4. **Trypanosomiasis and Sleeping Sickness.**—The discussion on trypanosomiasis was opened by Patrick Manson, who notes that the disease is milder in the native than in the European. In the latter there is irregular undulant fever, peculiar circinate erythema and such eye symptoms as choroiditis and iritis. Manson objects to the trypanosoma being considered the germ of sleeping sickness.

Christy describes the distribution of sleeping sickness along the Northern and Western portion of the Victoria Nyanza Lake showing that it is rapidly advancing, though its infecting area seems to be confined to within ten miles of the lake shore and corresponds rather with the tsetse fly distribution.

Dutton and Todd find that the disease extends well up the Gambia River. It seems to be mild in the natives. Its diagnosis is clinically impossible. Experimental inoculations of animals show the horse parasite to be more pathogenic than the human variety.

7. **Rheumatism.**—Walker and Ryffel refer to an earlier communication by Walker and Beaton in which they reported the discovery of a micro-organism associated with acute rheumatism to which they venture to give the distinctive term *Micrococcus rheumaticus*, differing in many respects from other streptococci. Attention is here called to the production of formic acid by this micrococcus and the following provisional statements are made:

1. The *Micrococcus rheumaticus* produces formic acid in very considerable quantity, and also at least one other acid of the fatty

acid series. 2. The acid (formic) is present not only in the filtered cultures of the organism, but it can also be extracted from the bodies of the micro-organisms themselves. The washed micrococci contain, in addition to formic acid, at least one of the higher fatty acids. 3. Ordinary streptococci, such as a streptococcus isolated from a case of erysipelas, only give rise to a small quantity of formic acid, so far as our experiments at present go. This observation may constitute a means of differentiation between the rheumatic micro-organism and other members of the streptococcus group. 4. Formic acid and probably another fatty acid are present in the urine during the course of acute rheumatism in appreciable amounts. From normal urine formic acid is either altogether absent or occurs in traces only. 5. Under the salicylic acid treatment of rheumatic fever formic acid is, so far as we have been able to investigate, reduced in quantity in the urine of the patient. 6. Formic acid is obtainable from the tissues of an animal (rabbit) suffering from acute arthritis due to the inoculation of the micro-organism.

They think formic acid is formed by the micro-organism, by oxidation of sacrolactic acid into formic and acetic acids. They remark that the connection of formic acid with the activity of the rheumatic micrococcus is of considerable interest in relation to the notion prevalent in county districts that bee-keepers are free from rheumatism. These individuals must necessarily be frequently subjected to the action of formic acid.

14 Defects in the Auricular Septum. Frank E. Tylecote.
15 *Tuberculosis and Cancer in New Zealand. W. J. Barclay.

8. **Infant Feeding.**—Hutchison summarizes as follows:

1. The first essential . . . is a definite plan on which to go and to avoid haphazard procedures. 2. Diluted cow's milk, condensed milk and peptonized milk may be regarded as the positive, comparative and superlative of digestibility respectively, and should be tried in that order until the digestive power of the child is suited. . . . 3. Periodic weighing of the child is the only test of the success or failure of the food selected. 4. In cases in which even peptonized milk fails to give good results great benefit often follows the administration of grey powder, even in cases in which there is no reason to suspect a syphilitic taint. 5. In spite of all care in the use of the above methods there remains a residuum of cases in which progressive wasting persists. Many of these seem to be babies who are unable to digest the casein of cow's milk in any form. 6. In such a case one should try to procure a wet nurse for the child, and, failing that, one must eliminate casein from the diet by making whey the basis of the feeding mixture. 7. The use of a patent food as the sole article of diet for a baby is rarely if ever necessary so long as cow's milk can be obtained, either fresh or condensed. 8. If a child is unable to digest much cow's milk it is often worth while to try the effect of adding a little starchy food to the diet even at an early age, for inability to digest milk appears to be sometimes accompanied by an unusual capacity for the conversion of starch.

13. **Appendicitis.**—Sherren notes the significance of cutaneous hyperalgesia in appendicitis and illustrates it by schematic diagrams and cases. He concludes:

1. Cutaneous hyperalgesia is probably present at some time during all first attacks of appendicitis, except, perhaps, in the fulminating type, and depends on tension within the appendix. 2. It may be absent in attacks after the first, if the first attack was of sufficient severity to destroy nerve tissue in the wall of the appendix. 3. When present in attacks subsequent to the first it often persists long after all other signs of the disease have gone, owing to the tension within the appendix being kept up by the presence of a stricture. 4. It gradually disappears during convalescence as the other signs of the disease clear up. 5. Disappearance of cutaneous hyperalgesia without improvement in the general condition of the patient is a sign of perforation or gangrene of the appendix, and should be a signal for immediate operation. 6. The presence of cutaneous hyperalgesia is no contraindication to operation. Abscesses may form and general peritonitis may develop while it is present. 7. Its absence, on the other hand, is of great importance. Absence of cutaneous hyperalgesia, the patient coming under observation early in the first attack of appendicitis, is a sign of gangrene of the appendix unless the case is obviously a mild one and the patient is rapidly getting well. 8. Cutaneous hyperalgesia is, as a rule, absent in cases of abscess of the appendix. 9. The age of the patient and the position of the appendix have no influence on the cutaneous hyperalgesia. 10. It is occasionally of use as an aid to the diagnosis of appendicitis.

15. **Tuberculosis and Cancer in New Zealand.**—Barclay gives a statistical study determining certain facts: 1. The death rate from tuberculosis is exceedingly low in New Zealand—only about one-half the English rate. 2. Cancer prevalence, on the other hand, seems to be practically equal to that in England. He concludes that the conditions favoring cancer are present to an equal extent in both countries.

19 *Further Notes on Experiments on the Pathology and Treatment of Malignant Diaease. E. R. Rost.

16. **Cataract.**—Pope has experimented with avoiding bandaging of the eye after operations, simply protecting it by a double eye-shade tied firmly around the head. By raising the head the patient is able to see. From his experience with wounds of the cornea, he thinks it a necessity to avoid bandaging in all cases of uncomplicated inflammation and injuries of the cornea and conjunctiva and to treat them simply by thorough cleansing with antiseptic washes followed by the application of an effective shade. The procedure has shown itself to be comparatively free from objections in hospital practice and he gives a history of the first twelve cases. The operation he employs for cataract is what is called the Drake-Brockman method. Instead of rupturing the capsule by a cystotome, Drake-Brockman used a Bowman's stop-needle and began by tearing the capsule of the lens. A full account was given in the *Indian Medical Gazette*, June, 1901.

19. **Cancer.**—Rost has seen benefit from the following treatment: A strict diabetic diet, two ounces of salt daily, rubbing salt ointment into the body and the local application of dilute hydrochloric acid, 2 per cent. In several cases there was a daily rise of temperature which gradually subsided as the treatment progressed. In some cases edema occurred around the growth, but this also subsided as the treatment was continued.

30 Panaris actinomycosique. L. Thévenot.

26. **Submedian Laparotomy.**—Longuet advocates what he calls submedian abdominal celiotomy, claiming that it is the shortest route, the line of the incision is always straight and rectilinear and is in accordance with the surgical principle to utilize a muscle as a support. Biologically it offers a greater vitality on the part of the lips of the wound than any other incision; the entire muscular functions of one side of the abdominal wall are left intact; the preservation of the linea alba confers greater solidity, and the interposition between the tiers of the suture of a sound, vigorous and intact muscle guarantees against post-operative hernia. In case of emergency operations in which haste is imperative the ordinary incision may be preferable, but for gynecologic operations in general he regards the submedian as a great improvement over the median laparotomy. His incision is about 12 cm. long, on a radius from the top of the symphysis, close to the median line at the base and diverging from it to about 3 cm. as the umbilicus is approached. The rectus has a tendency to retract to one side and is drawn further out of the way.

31. **Complications of Artificial Anus.**—Géraud observes that if prolapse of the mucosa through an artificial anus becomes annoying, the protruding mucosa should be excised. He has found 25 cases on record in which there was prolapse of the intestine through the anus, and describes 2 rather remarkable unpublished cases. He cautions that treatment should be prophylactic. The patient should be told to defecate reclining and without effort on the part of the abdominal muscles. Violent efforts, fatigue and dietary indiscretions should also be avoided. He regards the Saxtorph appliance as best adapted to allow passage of gases while preventing prolapse. In one of his personal cases there was eversion or evagination of the cecum, ileo-cecal valve and the orifice of the appendix. The protruding mass was fully 15 cm. long and every twenty-five to thirty minutes the ileo-cecal valve dilated and allowed the passage of some soft matters, similar to what is observed in the ureters emptying into the bladder. The mere fact of drinking a glass of milk at any time during the day caused evacuation of matters. Peas and beans emerged the day after they were eaten, apparently unmodified. In his second case there was double prolapse of the sigmoid flexure with a strangulated hernia of the small intestine into the prolapsed intestinal mass, thus forming an enormous T protruding from the artificial anus with a loop of small intestine incarcerated in the stem. Treatment consisted in removal of the loops of both intestines and the square of abdominal wall containing the anus. The specimen thus obtained is now in Terrier's museum. The protruding portion of the large intestine measures 20 cm. in length by 5 in diameter, and on the inner side four stumps of intestine project from the anus.

32. **Dilatation of Veins.**—Guibal does not believe in abstention from treatment in case of ampullary dilatation of the veins, as there is always danger of infection and coagulation of the contents. The possibility of fatal embolism has been proven by several instances on record, as also of hemorrhage and suppuration. Elastic stockings are useful for elderly persons or those with sedentary habits or who refuse operative treatment. Under other conditions, especially when the cystic dilatation is increasing or is causing serious trouble or is complicated with phlebitis, the tumor and adjacent veins should be excised between ligatures far into normal tissue. This puts an end to the tumor and benefits or cures the superficial varices by suppressing the reflux of blood. He reviews a material of 52 cases collected in the literature or personally observed, giving the particulars of each case.

35. **Tuberculous Rheumatism.**—Bouveyron studies the subject of the rheumatism complicating cutaneous tuberculous lesions to which attention has not previously been directed. He has observed 14 cases of rheumatism in persons affected with lupus with or without accompanying pulmonary tuberculosis. They were noted among 49 cases of lupus in his service during the last six months. There were no evidences of rheumatism among the 14 cases of lupus in children, but it was pronounced in 5 of the 12 men with severe lupus and in 7 of the 18 women. Rheumatism was thus manifest in 12 out of 30 cases of rebellious and mutilating lupus in adults, but was rare in adults with mild forms of lupus. The arthralgic form, with or without effusion or tumefaction of the joint, was most frequent, occurring in 8 out of the 12. These arthralgias are usually moderately painful, torpid, tenacious and rebellious to all the classic methods of treatment. They sometimes disappear for a time and then recur in the same or another joint. They may improve without apparent cause or under the influence of a febrile affection. The condition of the accompanying lupus does not seem to affect them nor the general health of the individual in question. The ostealgic or hyperostosic form was encountered only in women, and in 4 out of the 7 cases in this class. Two other women with tuberculides also exhibited painful hyperostosis, which raises the proportion to 6 out of 9. In one case of ostealgia of the two femurs there did not seem to be hyperostosis. In 3 out of 12 cases the rheumatism assumed the form of hydrarthrosis. In one of his 2 cases of tuberculides the rheumatism assumed the form of multiple painful hyperostosis, and in the other of hyperostosis, spina ventosa and polyarthritis so acute and painful that it simulated true rheumatism. The general condition of both these patients was very poor. Bouveyron adds that the limitation, recurrences and fixity of the rheumatismal manifestations suggest some local germination and reviviscence rather than general toxic action from a distance. Poncet, who first described the rheumatism of tuberculosis, used to say that there is nothing to prove that the action of the tubercle bacillus is restricted to the formation of granulations, tubercles and fungous growths. This seems to be accepted as an article of faith, but no one to date has demonstrated that this anatomo-pathologic signature is absolutely necessary, and that Koch's bacillus may not determine an ordinary inflammatory process when ensconced in the bone or synovial membranes.

36. **Tumors of the Intercarotid Body.**—Reclus and Chevassu describe a case of a tumor which shelled out from the bifurcation of the common carotid without difficulty, and state that it is the eleventh on record. They remark that the possibility of a tumor in this intercarotid body should be borne in mind when a single tumor is observed in the carotid region, rather soft, pulsating without expansion, and developing very slowly, near and above the thyroid gland. Such tumors are always solid and perivascular. In 4 of the published cases the tumor was differentiated before operation. The only other neogrowths which could be confounded with it are an aberrant thyroid tumor and a mixed branchioma. The former has never been discovered at the carotid bifurcation and the latter is always more superficial and harder. In only 2 of the cases on record was it possible to dissect out the tumor without injury to the vessels. In the 8 others the entire fork of the carotid was resected and 2 of the patients succumbed, one from hemorrhage and the other from broncho-pneumonia ascribed to section of the vagus. The 6 patients who recovered all presented disturbances of various kinds. One of Maydl's patients had hemiplegia the fifth day with aphasia, the latter not entirely vanishing after four years. His second patient complained of a constant oppression in the back of the throat, and in his third patient the voice has been hoarse and nasal, with inability to swallow solid food readily, and a tickling in the throat which induces constant coughing. The pneumogastric and sympathetic had both been severed in this case. The patient has also occasional vertigo, with deviation of the tongue and contraction of the pupil. Gersuny's patient has still a slight paresis of the left vocal cord. In one of the 2 cases reported from Russia the pneumogastric had been divided, but further details are not given, and in the other there was deviation of the tongue and one corner of the mouth. These after-disturbances condemn extensive resection of the nerves and vessels on account of a tumor in the carotid gland. These growths are probably not malignant; they may exist for a long time, possibly indefinitely, without inducing serious symptoms or even discomfort, and resection of the nerves and vessels is a remedy worse than the original evil. Resection may be found necessary to conclude the operation, and hence the writers do not advocate operating unless the surgeon's hand is forced by severe functional disturbances. They give the particulars of the series mentioned, with cuts of some of the cases. They show that some of the smaller tumors were more intimately adherent to the vessels than the larger ones. (Scudder also reports and illustrates a case in the current number of the *Am. Journal of the Medical Sciences.* He removed the adherent vessels with the tumor.)

40 to 42. Disturbances in Development of Kidney.—Meyer discovered a peculiar irregular appearance in the kidneys of a female infant nine weeks old, who presented other deformities. Parts of the kidneys seemed to be normal, while in other parts there were no convoluted tubules to be found, although the Malpighi corpuscles and the straight tubules were normal. He also examined pathologic kidneys of calves and kidney cysts in children and adults. The findings in all corroborate the assumption that the canal system of the kidney develops from two separate foundations or *Anlagen*. The researches of Schenkl and Beck at the veterinary pathologic institute at Berne also confirm this view.

43. Accessory Pancreas.—Thorel found the accessory pancreas in the stomach or intestine in 3 cases; in one it was double, and one pancreas was in the jejunum and the other in its mesentery. He has encountered 7 cases of accessory pancreas in all, and in each one, with the exception of the last mentioned, the organ had an opening into the intestine. Langerhans' islands were absent in nearly every one. He ascribes the origin of these accessory organs to displacement of germinal tissue.

44. Malakoplakia of the Bladder.—Hansemann found a number of peculiar, yellowish, flattish fungus-like growths in the mucosa of the bladder and of the dilated ureters in the 2 cases described. They had not caused any clinical symptoms, although some were ulcerated and confluent. He does not know how to classify the affection and proposes the descriptive term of malakoplakia vesicæ, from the Greek word malako, soft, and plakia, patch.

64 Two Cases of Rupture of Uterus. E. Puppel.—Zur Lehre von den penetrierenden Zerreissungen der weichen Geburtswege intra partum.

51. Twin Pregnancy Intra- and Extra-Uterine.—Geyl remarks that not a single case similar to the one he describes was found by G. Zinke in his compilation of 88 cases of simultaneous intra- and extra-uterine pregnancies during the last two centuries. The case is distinguished by the fact that the fetus in the uterus died about the third week of its development while the extra-uterine fetus, with placenta attached to the floor of the pelvis, continued to develop normally until about the fourth month. The patient succumbed to hemorrhage.

53. Funnel Pessary.—Schatz proclaims that his funnel pessaries have rendered excellent service in more than 300 cases, and possess several advantages over all others in use. They are shaped like a funnel with all the edges well rounded, but are not hollow, having merely a small passage through the center to allow escape of secretions. They separate vertically into halves and each half is inserted separately. The halves fit together spontaneously and support the parts in genital prolapse and in cases of urinary incontinence. The patients soon learn to insert and remove the pessary themselves, as he insists on its being removed every night, the vagina cleansed, the pessary sterilized and replaced next morning. He has the pessaries made in ten sizes to fit all conditions, the stem the same length in all.

54. Is Injury of Round Ligament in Herniotomies Followed by Retrodeviation?—Gold answers this question in the negative.

55. Drawbacks of Raising the Pelvis.—Kraske has stated that the Trendelenburg position caused a tendency to paralysis of the anterior tibialis, and to emphysema of abdominal walls, both of which can be easily avoided. He further asserted that he had witnessed severe disturbances in circulation in 2 corpulent subjects who had exhibited symptoms of myocarditis previous to the operation. In a few other exceptional cases he has observed intestinal occlusion, aspiration of stomach contents and apoplexy, all of which he attributed to the raising of the pelvis. Franz reports that none of these mishaps have been noted at the Halle clinic in the course of 745 laparotomies, but he calls attention to a disadvantage of the position hitherto unappreciated. This is the diminished abdominal respiration during the time that the pelvis is raised. The respiration in the lungs does not compensate for it, as he shows by respiration curves, and consequently the patient suffers from abnormally deficient respiration. He further announces that he has found that bronchitis was four times more frequent after an ether nacrosis when the operation had been performed with the pelvis raised than when the patient had been simply reclining. The cases of bronchitis after chloroform narcosis were likewise more numerous, but not to the same extent as with ether. The subject does not get his normal supply of oxygen while in the Trendelenburg position, and this must aid in depressing the general condition. This fact may even explain why patients bear a vaginal operation so much better than a laparotomy.

56. Tubal Pregnancy.—Orthmann reviews his experience with 45 cases, and relates the particulars of 8 particularly interesting ones. Four of the total number died. In 2 the tubal pregnancy occurred more than once.

57. Apparatus for Sterile Water Supply.—The apparatus consists of a double cylinder somewhat on the principle of a Russian samovar or tea urn. It is made for convenient handling with a capacity of about a quart and a half, but can be as large as required. The spout is long and turns up and over so that the nose of the spout fits into the apparatus near the top and is sterilized with the water. When ready to use the spout is pulled down and can be adjusted at any angle by a thumb screw. The water is heated with live coals like a samovar or by standing the apparatus on the stove.

58. Lacerations of Vagina and of Muscular Floor of Pelvis as Cause of Prolapse of Uterus.—Schatz proclaimed as long ago as 1883 that lacerations of the muscular floor of the pelvis during childbirth were a frequent cause of prolapse later. He states that no one paid any attention to his remarks on the subject except in North America. In the meantime he has collected further data and now announces that his assertions were not sweeping enough, and that detachment of the vagina is a certain and frequent source of prolapse. He describes the anatomic conditions in detail, showing that the true conditions do not seem to be appreciated in the text-books. During childbirth the vagina is liable to become detached either by the bearing down of the woman or by the direct action of the emerging fetus. The anterior wall of the vagina usually escapes, but the posterior wall is liable to become detached, and even to be slit in one or more places, and the muscular attachments are wrenched out, thus depriving the vagina of its power of transverse elastic contraction.

69 Conclusion of Report on Foot-and-Mouth Disease. Loeffler.

65. Physiologic and Pharmacologic Action of Silicic Acid.—Schulz protests against the general assumption that silicic acid is a comparatively insignificant substance from the standpoints of physiology and pharmacology. The respiration and vascular system did not seem to be affected, but ingestion of small amounts of silicic acid caused marked derangement of the nervous system. Headache occurred, general or local, sometimes accompanied by vertigo. The eyes burned and smarted. In some of the tests the subjects complained of somnolence with inability to concentrate their attention; others became nervous and irritable; the gait was uncertain and the hands trembled. A cutaneous reaction resembling acne pustules or a papulous exanthem was also noted, and hyperidrosis with acid sweat and desquamation. The hair and beard displayed a tendency to drop out, and the nails seemed to grow faster. The digestive tract reacted to the acid with flatulence and colic, rumblings and increased desires for stool. Constipation alternated with diarrhea, and the stools were remarkably yellow, both in man and animals. There was no diuresis except when the acid had been taken for a long time. Polyuria developed with smarting during urination in some of the subjects, while in others there was retention, the urine concentrated and reddish until diuresis became established. In all the tests the legs felt as if weighted with lead and were easily fatigued. Dull pains were also noted in the tibiæ, increasing during rest and subsiding after exercising. The joints also ached and were stiff, suggesting the symptoms of lead-poisoning, etc.

70. Chemical Properties of Leucocytes.—Meyer gives the details of several cases of acute and chronic leukemia, and then relates the results of chemical tests of the blood from these patients. Fresh, centrifugalized blood did not respond to the guaiacum test at all, but if distilled water was added to the blood before the tincture of guaiacum, the fluid turned blue at once. Not a trace of the guaiacum reaction could be obtained with the blood of the patient with acute lymphatic leukemia nor with extracts of human and animal thymus and lymph glands. Pus did not give the reaction until it had stood for some time or had been diluted with water. For these and other reasons which he mentions he asserts that there can be no doubt that the polynuclear and probably also the mononuclear neutrophile cells of the blood contain a substance which can be dissolved out by water, and which turns the guaiacum tincture blue in the absence of peroxids. The substance in question is entirely lacking in the lymphatic apparatus. He accepts it as an intracellular oxidating ferment. It does not give the reaction after boiling, but the response is positive again if hydrogen dioxid is added to the boiled fluid. It has also the property of oxidizing phenolphthalin in alkaline solution into phenolphthalein. Phenolphthalin is the product of the reduction of the latter, and is a colorless, soluble powder. If an aqueous solution is added to the solution of the above ferment or to the diluted blood of a myelogenic leukemic patient, the fluid turns a permanent purple. This reaction parallels the findings of the guaiacum test. Both of these tests may be positive with blood in high neutrophile leucocytosis. In several cases of pneumonia with 19,000 leucocytes, both of these reactions were positive, the phenolphthalin reaction most pronounced. But with diminishing numbers of leucocytes they subsided and were no longer to be distinguished when there were only 15,000 to 16,000. It is thus established that entirely normal neutrophile leucocytes contain the oxidating ferment, and it is thus not the prerogative of pus cells and of the cells in myelogenic leukemia alone. He adds that the simple phenolphthalin test not only gives an approximate estimate of an existing hyperleucocytosis, but it indicates besides the kind of leukemia present. He is now studying to determine whether it may not serve for quantitative determination of the leucocytes. The results of this research on the chemical properties of the leucocytes indicate that the terms acute lymphatic leukemia or lymphocytemia are correct. He describes in conclusion studies of the response to neutral red, and although they were meager, yet they suggest that it may be possible to detect in the blood the destruction of leucocytes evidenced by excessive elimination of urea in the urine.

72. Absence of Tube Casts in Nephritis.—Treutlein announces on the basis of a case observed and considerable experimental research, that the colon bacillus has the property of inducing destruction of the tube casts. Consequently, severe nephritis may occur without any casts being found in the urine. The colon bacillus may induce this "cylindrolysis" by its presence in the bladder or in the kidney itself. The ferments of the bacillus are unable alone to accomplish it.

73. Sudden Death in the Newly-Born.—Hofmeister describes 3 cases to show the liability to error in these cases. The births occurred under his eyes and only the most careful examination disclosed even a possible cause for the death of the child just before or after delivery. In one the microscope showed minute changes in heart and lungs, possibly rendering them unable to adapt themselves to extra-uterine life; in another some of the blood vessels in the placenta were obliterated; in the third, meconium was found in bronchi and lungs and yet the child was stillborn. The deaths might easily have been unjustly ascribed to the mothers under other circumstances.

75. Treatment of Placenta Previa.—Hammer reviews the experience of the Würzburg clinic with placenta previa, 107 cases in all. In 19, the records mention placenta centralis; in 70, previa lateralis, and in 18, low placenta previa. The mortality was 7.47 per cent. of the mothers and 54.2 per cent. of the children, but the maternal deaths were due to eclampsia, sepsis, lysol poisoning or air embolism in 4 cases and 3 succumbed to hemorrhage from atony of the uterus post-partum. The experience with the metreurynter introduced inside the fetal membranes has been very favorable.

76. Outlining Left Heart.—Engel recommends the use of a hard rubber plessimeter for percussion. He starts from a mark on the upper part of the heart outline, which can be easily determined by percussion to the left of the manubrium sterni. He then places the plessimeter rod on the mark with half its diameter projecting and by percussion determines the proper location of the rod which is likewise marked. By proceeding slowly in this way, advancing only half the width of the diameter of the rod at a time, it is possible to outline the heart with great accuracy. A stick of sealing wax will answer for the rod if necessary. His findings on more than 100 subjects were always confirmed by other tests and anatomic examination.

77. Intravesical Segregation of Urine.—Keydel reviews the various instances of application of the Luys or Cathelin intravesical urine separators as published by various other writers, and adds 4 from his own experience. He has collected 25 published since the authors' communications, and in

by far the largest majority the results were eminently satisfactory, while in the hands of the authors the results have always been brilliant and their list now numbers hundreds. Their success is probably due to their careful discrimination of the subjects, "asking the permission of the bladder," and remembering that the organ is not so sensitive to contact as to distention.

79. **The Specific Gravity of the Living Human Being.**—Jamin and Müller have been conducting laborious researches at Erlangen to determine the exact specific gravity of different individuals, the quotient of weight and volume. They constructed for the purpose a tall tub, a cylinder nearly full of water and containing a convenient seat. The subject, entirely naked, steps from a platform into the cylinder and seats himself. Then at a given moment he slips down into the water until it covers him entirely and the displacement of the water is registered outside. In order to make the procedure less annoying they finally modified it by having the seated subject merely lean back or forward until the head was submerged to a line from the chin to the roots of the hair. This was accepted as the approximate figure and used for calculations. As it does not pretend to be as exact as complete submersion they call it the "specific gravity equivalent," and have found it as useful for purposes of comparison as the correct figure would be. They have determined this equivalent for 118 persons. It is highest in youth and gradually declines from 1130 at 8 years to 1061 between 50 and 90 in male subjects, and from 1106 between 10 and 15 to 1065 between 50 and 90 in female subjects. The average for all ages and both sexes is 1088 in health, and 1074 in pathologic conditions. The equivalent in obesity was only 1049, 1037 and 1004 in 3 obese men; the normal equivalents for their age would have been 1061, 1066 and 1066. The value of the method lies in the information that it imparts in regard to the composition of the body, which has hitherto escaped our methods of weighing, etc., and will prove particularly valuable in case of obesity and dropsy. The investigations were repeated a number of times on the same subject in many instances, and the variations in the findings were found to be almost imperceptible for the same individual under similar conditions.

80. **Aid of Roentgen Rays in Internal Medicine.**—De la Camp remarks that internal medicine has not profited very materially by the Roentgen rays to date except in clinical diagnosis in combination with other methods of investigation.

81. **Hemorrhage and Pains in the Kidneys.**—Klink has found 18 operations on record undertaken on account of renal hemorrhage on a nervous basis. In 14 other cases the operation was merely on account of pains in the kidney, and in 23 for both hemorrhage and pain. The results have been that 69 per cent. were cured, 5 improved and in only 5 per cent. did the operation fail to relieve. Nine, or 16 per cent., have died. As a contribution to the subject of neuropathic renal hemorrhage he describes the unpublished case of a man of 25, previously healthy, who noticed blood in the urine for four weeks after a violent attack of pain in the left kidney, removing to the right kidney the next day, and recurring occasionally since then. When the bladder was opened by a high incision blood was seen to drip from one ureter. No further intervention was attempted and the symptoms all vanished. The chloroform narcosis may have been a factor in the cure, or it may have been due to suggestion or to reflex action on the kidney.

82. **Hot-Air Treatment of Biliary and Renal Lithiasis.**—Sachs illustrates an apparatus which he has devised for the application of a stream of superheated air to the kidney or liver region. The air is focused on the spot by a funnel arrangement. The results obtained have surpassed his most sanguine expectations.

83. **Internal Affections and Sudden Death After Healing of Infantile Eczema.**—Cohn discusses the subject and relates that a child of fifteen months exhibited signs of mild nephritis three days after the institution of treatment of chronic eczema of the scalp. Application of zinc oxid and oil, equal parts of each, cured the eczema, but was followed by symptoms of nephritis, edema of hands and feet, with albumin and casts in the urine.

84. **Scopolamin in Gastric Affections.**—Pickardt found that in 3 cases of excessive secretion of gastric juice, conditions were restored to normal by administration of .3 mgm. scopolamin bromid in water twice a day for four weeks. No by-effects were observed. The remedy proved especially beneficial in a case complicated by exophthalmic goiter.

87 *Ueber den Nachweis des Urobilins und seine Ausscheidung bei Carcinom. A. Braunstein.
88 *The Collective Cancer Inquiry in Spain. H. Leyden.

86. **Journal for Cancer Research.**—This periodical is published by the German committee for cancer research whose work has been frequently referred to in these columns. The name "cancer," *Krebs*, is deliberately chosen to express every kind of malignant tumor not connected with an infectious disease, thus excluding syphilids and actinomycotic tumors and the tumors of leukemia and pseudo-leukemia. The publication announces its scope as chiefly the clinical side of the cancer problem, with prophylaxis, treatment and casuistics, reviewing international literature, with abstracts, bibliographies and transactions of similar organizations elsewhere.

86. **Urogenital Cancer.**—Posner does not attempt to formulate any conclusions but merely reviews various aspects of the subject. He mentions that only 30 cases of supposed conjugal cancer, located on the genitalia, are on record, and these are not all above criticism. Contact infection and operative implantation are much more frequent. The theory of the origin of cancer from aberrant cells of germinal tissue is sustained by the frequency of cancer of the kidney in childhood. Rohrer found that in 37 out of 96 cases the patients were under 10 years of age. He emphasizes the fact, however, that scarcely any of them were carcinomata. The connection between metaplasia and carcinoma is becoming more probable. Halle, for instance, has noted preceding gonorrheal strictures in 12 out of 20 cases of carcinoma of the urethra, and others have reported cases of hard cancer developing on a basis of leucoplasia in the bladder. Still more evident is the connection between cancer and fistula of the urethra, tar, paraffin and chimney sweeping. Baum has demonstrated that chimney-sweeper's cancer was unknown in Hanover until wood was supplanted by coal for fuel. Posner knows of an unpublished case in which a worker in tar developed a typical cancer of the scrotum accompanied by one in the bladder. Since Rehn first called attention to the bladder tumors of men employed in anilin works, other cases have been reported until at present there are 6 authentic ones on record, 4 of carcinoma and 2 of sarcoma. Posner has seen a cancer in the bladder in a man employed in naphthol whose brother working beside him had stones in the bladder. Attempts to reproduce tumors of this kind in animals have always proved negative to date, and the spectrum did not reveal any changes in the blood. The animals died after inhaling the anilin, toluidin or nitrobenzol with symptoms of anemia and general prostration, in coma or in convulsions. Direct trauma seems to participate, if at all, in the etiology of carcinoma of the penis alone. Some authorities are inclined to regard injuries during birth as a factor in internal cancer. Posner is dubious in regard to the transformation of a benign into a malignant neoplasm, believing that the tumor was prob-

ably malignant from the start. Albarran found evidences of unmistakable cancer in 68 out of 88 cases assumed to be in this category. This applies also, Posner believes, to malignant recurrences after extirpation of a supposed benign growth, and also to growths in the vicinity of a cancer, and to the senile hypertrophy of the prostate, and to gynecologic affections. In conclusion, he refers to the fact that cancer of the bladder displays very little tendency to metastasis. Many cases run their entire course without a trace of enlargement of the glands or metastases.

87. **Urobilin with Carcinoma.**—Braunstein analyzes his findings in 22 cases of carcinoma. He found that it develops without essential urobilinuria if the neogrowth is not located in the liver and in the absence of fever or other complications. Urobilinuria appears when the liver is invaded by metastasis, when the carcinoma ulcerates and when a pneumonia or suppurative bronchitis develops secondarily. If the carcinoma is located in the liver there is pronounced urobilinuria and frequently bilirubinuria as long as the biliary passages are not compressed and the bile finds ready outlet. As soon as one of the biliary passages becomes obstructed the urobilin disappears completely from the urine, but the bilirubinuria persists.

88. **Cancer Inquiry in Spain.**—Leyden was physician to the German legation at Madrid at the time this collective inquiry was made, September 1, 1902. He states that the circulars were returned blank by 294 physicians, while 298 reported cancer patients. Of these, 116 were men and 182 women. Certain towns seemed to be entirely exempt from cancer. Not a single case was known to the eight physicians on the Canary islands, nor to the ten physicians in the Ceuta district in Africa.

89. **Laryngectomy.**—Cortes removed the larynx in a man of 67 on account of a carcinoma on one vocal cord without glandular involvement, and reports that when seen nearly three years later the man was in perfect health. He was able to make himself understood by those around him by speaking in what Cortes calls the "aphonic pseudo-voice" frequently observed after this operation.

91. **Defensive Action of Omentum.**—Pirrone has been studying further the defensive action of the omentum which De Renzi and Boeri have recently proclaimed as quoted on page 887. He examined the omentum after it had encapsulated the spleen, to determine if the process was similar to that of ordinary encapsulation or whether the omentum undergoes special histologic changes. He experimented on rabbits and cats and found that in fact the spleen, after necrosis from ligature of its vessels, soon became enveloped by the great omentum. The inflammatory process in the membrane entails a rapid formation of connective tissue which not only forms a capsule around the spleen but the cells have a phagocytic action, devouring the detritus of the spleen. By means of this dual action, plastic and phagocytic, the great omentum finally ends by destroying the spleen, behaving toward it like the endothelium of the vessels in respect to a thrombus. After extirpation of the spleen there is nothing to indicate that the great omentum undergoes lymphoid transformation to compensate the missing organ. The phenomena observed establish that the great omentum has a decided protecting action in the peritoneum, and under certain circumstances plays an important part in the defense of the abdominal cavity and hence of the entire body.

92. **Studies of Action of Organ Extracts.**—Ghedini injected dogs and lambs subcutaneously with extracts of various organs, continuing the treatment for one to several months. He then found evidences of inflammation of a degenerative and infiltrative type in the superficial lymphatics, especially those in the axilla and inguinal regions, and in the liver, kidneys, and spleen, while the thyroid gland was in a condition of hyperfunction. No other reaction could be discovered. These results were constant in his 14 animals, and he assumes that the organ extracts acted like toxins in the circulation without any specific affinity for the corresponding organs. He is now engaged on a second series of animals; the results to date apparently confirm those reported.

93. **Tuberculosis and Leukemia.**—Prodi reports a case of the coincidence of these affections and assumes a causal connection between them. He also refers to the mildness of the tuberculosis when associated with leukemia or pseudoleukemia. The tuberculous lesions are generally discovered only at the autopsy.

95. **Pathogenesis of Post-Operative Hematemesis.**—Tonarelli describes 2 cases of fatal hematemesis occurring one and five days after operations on account of biliary lithiasis in the first and a hydatid cyst in the liver in the other case. In both there had been retention of bile, and he thinks it possible that this may have been a factor in the production of the hemorrhagic tendency. The hemorrhage was parenchymatous, involving the entire capillary system of the stomach in the case that came to the dissecting table, and the symptoms had been identical in the other. Hayem reported a case in which absorption of bile from the peritoneum had induced a hemorrhagic diathesis. The chloroform may also have aided in disturbing the balance of the already unstable conditions in the circulatory system. The trauma of the operation with its manipulation of the nerves in the peritoneum and omentum may likewise entail a kind of shock to the vasomotor nerves, and hence induce transient disturbances in the circulation through the viscera, sufficiently intense while they last to explain the phenomena observed.

96. **Tansini's Technic and Results in Abdominal Surgery.**—Palleroni reviews his notes taken during ten years' work as assistant to Tansini. He mentions that the majority of the 131 laparotomies were undertaken on account of tumors. The mortality was 9 per cent. and 119 patients were restored to health. The fatalities were almost exclusively among patients with myomata. In the other groups the mortality was null, or not over 1 per cent. One of the ovarian cysts removed weighed 40 kilograms (88 pounds). The patient was in a very serious condition, but is now in good health. Two days before the operation the patients are prepared by an oil or saline purge, and after the mechanical cleansing of the entire abdomen, shaving and applying turpentine and sulphuric ether, it is washed with 1 per 1,000 sublimate and a cloth wet with the same is applied for half an hour to cover the entire abdomen. Fifteen minutes before the chloroform, 1 cgm. of morphin hydrochlorate is injected. The entire body is warmly covered except for the field of operation, and the temperature of the room is 77 F. The nostrils are kept closed during the chloroform administration to avoid reflex action during the first stage of the narcosis, using a special nose clamp devised by

Tansini. After the abdominal walls are incised the deep is followed by superficial anesthesia, just keeping the patient slightly drowsy. Tansini makes constant use of the galvanocautery knife, believing that it answers several purposes at once. He prefers a narrow opening into the abdomen, and operates as far as possible extraperitoneally. He never uses an antiseptic in the toilette of the abdomen, fearing that it might irritate, and wipes it dry with gauze sponges wrung out of tepid sterile water. He very rarely drains. The particulars of the various groups and most interesting cases are added.

97. **Chemistry of Stomach Under Certain Drugs.**—Pirrone's experience has been that in gastric affections the behavior of the hydrochloric acid and of the ferments is not identical; only the pepsin and the rennet behave alike. In Reichmann's disease, along with the increase of acid the ferments will be found much increased, but when the amount of acid diminishes under the influence of atropin, the quantity of the ferments is not modified. The ferments may occur in normal proportions in chronic gastritis with disappearance of the free acid, and also in hypochlorhydria of nervous origin. In cases of carcinoma, the acid secretion is impaired before that of the ferments, which may persist in normal amounts for a long time. Strychnin stimulates the secretion of the acid in chronic gastritis, with not very advanced lesions, and in hypochlorhydria of nervous origin, but it does not affect the ferments. The action of both atropin and strychnin is almost null when administered other than by the mouth, but that of pilocarpin is almost equal by the subcutaneous route. The latter increases the secretion of acid but does not affect that of the ferments. Bitter tinctures, alkalines and alcohol in small doses do not exert any influence on the chemistry of the stomach. Daily lavage of the stomach does not affect the secretion of hydrochloric acid, pepsin or rennet, but reduces the percentage of total acidity in the stomach content.

98. **Cytotoxic Serums.**—Cafieri's results were practically the same as those obtained by Ghedini mentioned above.

99. **Studies of Vaccine.**—Casagrandi announces that sterile, filtered vaccine, which was unable to cause the formation of a pustule when inoculated in the skin of dogs or to induce any reaction on the cornea of rabbits, yet conferred immunity on them, so that subsequent injection of active virus did not cause infection as in the controls. Similar tests on man resulted differently. The filtrates and dilutions which confer immunity on the dog do not render human subjects immune. On the other hand, he found that if the dogs were inoculated with the active virus before the cutaneous lesion from the first vaccination had entirely healed, infection resulted, as also when the dogs were inoculated simultaneously with the vaccine and a staphylococcus derived from vaccine pustules on other dogs. He thinks that these facts indicate the participation in the vaccine pustule of some pyogenic germ which finds in it special conditions for its development.

100. **Plastic Operation on Gall Bladder.**—Baldassari was so successful in his tests of resection and subsequent plastic operations on the gall bladder of dogs that he thinks the method is also applicable to man. He used a flap for the purpose cut from the peritoneum and re-enforced by a thin layer of muscle from the vicinity. The muscular side is turned inward and the flap is sutured so that it extends for several millimeters beyond the defect on all sides. The peritoneal outer side of the flap was sutured with fine silk to the gall bladder. The results were perfect, but he found that the flap served only the purpose of a temporary stop-gap, under which the gall-bladder regeneration proceeded undisturbed until the integrity of the organ was restored. He describes his negative experiences with other kinds of flaps. He cuts the muscle flap along the edge of the abdominal incision and keeps it wrapped in gauze wet with saline solution while the gall bladder is being resected. In some experiments he removed nearly all the wall of the gall bladder on one side, the subsequent plastic operation being as successful as with smaller resections.

106. **Experimental Tuberculosis of the Epididymis.**—Delli Santi was able to induce tuberculous epididymitis in dogs by introducing tubercle bacilli into the urethra. The bacilli found their way into the epididymis and testicles but caused no harm (during the forty-five days' limit of the tests), unless special conditions were produced which favored their proliferation. One of these conditions was venous stasis, passive congestion from ligature of the vessels in the spermatic cord. Under these circumstances a tubercular lesion soon developed and the infection spread to the entire organ. This research establishes the possibility of contagion from tuberculous lesions in the female genitalia, and explains the fact that the left testicle is most frequently affected, as the anatomic conditions favor the predisposing conditions of defective circulation such as were produced artificially in the experiments.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

A Dictionary of Medical Science. Containing a Full Explanation of the Various Subjects and Terms of Anatomy, Physiology, Medical Chemistry, Pharmacy, Pharmacology, Therapeutics, Medicine, Hygiene, Dietetics, Pathology, Bacteriology, Surgery, Ophthalmology, Otology, Laryngology, Dermatology, Gynecology, Obstetrics, Pediatrics, Medical Jurisprudence, Dentistry, Veterinary Science, etc. By Robley Dunglison, M.D., LL.D., Late Professor of Institutes of Medicine and Medical Jurisprudence in the Jefferson Medical College of Philadelphia. Twenty-third Edition. Thoroughly Revised, with the Pronunciation, Accentuation and Derivation of the Terms. By Thomas L. Stedman, A.M., M.D., Fellow of the New York Academy of Medicine. Cloth. Pp. 1212. Price, $8.00. Philadelphia and New York: Lea Brothers & Co. 1903.

The Practical Medicine Series of Year Books. Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Issued Monthly. Under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Volume IX. Physiology, Pathology, Bacteriology, Anatomy, Dictionary. Edited by W. A. Evans, M.S., M.D.; Adolph Gehrmann, M.D., and William Healy, A.B., M.D. August, 1903. Cloth. Pp. 233. Price, $1.25. Chicago: The Year Book Publishers.

A Surgical Handbook. For the Use of Students, Practitioners, House Surgeons and Dressers. By Francis M. Caird, M.B., F.R.C.S. Edin., Assistant Surgeon, Royal Infirmary, Edinburgh, and Charles W. Cathcart, M.B., F.R.C.S. Eng. and Edin., Surgeon, Royal Infirmary, Edinburgh. With Very Numerous Illustrations. Twelfth Edition. Morocco. Pp. 323. Price, $2.75. London: Charles Griffin & Co., Ltd. Chicago: W. T. Keener & Co. 1903.

Modern Microscopy. A Handbook for Beginners and Students. Combining: 1. The Microscope and Instructions for Its Use, by M. I. Cross. 2. Microscopic Objects, How Prepared and Mounted, by Martin J. Cole, Lecturer in Histology at Cooke's School of Anatomy. Third Edition. Entirely Revised and Enlarged, to which is Added 111 Microtomes, Their Choice and Use. Cloth. Pp. 292. Price, $1.50. Chicago: W. T. Keener & Co. 1903.

The Principles and Practice of Hydrotherapy. A Guide to the Application of Water in Disease. For Students and Practitioners of Medicine. By Simon Baruch, M.D., Professor of Hydrotherapeutics in the New York Post-Graduate Medical School and Hospital. Second Edition, Revised and Enlarged. With Numerous Illustrations. Cloth. Pp. 496. Price, $4.00 net. New York: Wm. Wood & Co. 1903.

Takosis, A Contagious Disease of Goats. A Preliminary Report on Its Nature, Cause and Prevention. U. S. Department of Agriculture. By John R. Mohler, V.M.D., A.M., Chief of Pathological Division, Bureau of Animal Industry, and Henry J. Washburn, D.V.S., Acting Assistant Chief of Pathological Division, Bureau of Animal Industry. Paper. Pp. 44. Washington: Government Printing Office. 1903.

A Manual of Operative Surgery. By Sir Frederick Treves, Bart., K.C.V.O., C.B., LL.D., F.R.C.S., Sergeant Surgeon-in-Ordinary to His Majesty, the King. New Edition. Revised by the Author and Jonathan Hutchinson, Jr., F.R.C.S., Surgeon to the London Hospital. With About 450 Illustrations. In Two Volumes. Volume I. Half Morocco. Pp. 750. Philadelphia and New York: Lea Brothers & Co.

A Text-Book of Clinical Anatomy. For Students and Practitioners. By Daniel N. Eisendrath, A.B., M.D., Clinical Professor of Anatomy in the Medical Department of the University of Illinois (College of Physicians and Surgeons). Beautifully Illustrated with 153 Illustrations, a Number in Colors. Cloth. Pp. 515. Price, $5.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

Intracranial Tumors Among the Insane. A Study of 29 Intracranial Tumors Found in 1,642 Autopsies in Cases of Mental Disease. By I. W. Blackburn, M.D., Pathologist to the Government Hospital for the Insane, Washington, D. C. Illustrated by 30 Plates and 65 Microscopical Drawings. Cloth. Pp. 95. Washington: Government Printing Office. 1903.

Diseases of the Skin. An Outline of the Principles and Practice of Dermatology. By Malcolm Morris, Consulting Surgeon to the Skin Department, St. Mary's Hospital, London. With 2 Colored Plates and 58 Plain Figures. New Edition. Flexible Cloth. Pp. 642. Price, $2.50. Chicago: W. T. Keener & Co. 1903.

A Text-Book of Diseases of Women. By Barton Cooke Hirst, M.D., Professor of Obstetrics in the University of Pennsylvania.

Sumptuously Illustrated with Some 650 Mostly Original Illustrations, Many in Colors. Cloth. Pp. 675. Price, $5.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

THE PRINCIPLES AND PRACTICE OF SURGERY. Designed for Students and Practitioners. By George Tully Vaughan, M.D. (Univ. of Va.), Assistant Surgeon-General U. S. Public Health and Marine-Hospital Service. Cloth. Pp. 568. Price, $3.50. Philadelphia and London: J. B. Lippincott Company. 1903.

TRANSACTIONS OF THE AMERICAN PEDIATRIC SOCIETY. Fourteenth Session, Held at Boston, May 26, 27 and 28, 1902. With Addenda from the Thirteenth Session and an Index. Vols. I.-XIV., Inclusive. Edited by Walter Lester Carr, M.D. Cloth. Pp. 310. Reprinted from the Archives of Pediatrics. 1902.

ELEMENTARY BACTERIOLOGY. By M. L. Dhingra, M.D., C.M. Edin., Diplomate in State Medicine, University of Cambridge. With Colored Frontispiece and Illustrations in the Text. Cloth. Pp. 145. Price, $1.12 net. London, New York and Bombay: Longmans, Green & Co. 1903.

PHYSICAL DIAGNOSIS OF DISEASES OF THE CHEST. By Richard C. Cabot, M.D., Physican to the Out-patients, Massachusetts General Hospital. Second Revised Edition. With 147 Illustrations. Cloth. Pp. 319. Price, $2.50 net. New York: Wm. Wood & Co. 1903.

A LABORATORY GUIDE IN URINALYSIS AND TOXICOLOGY. By R. A. Witthaus, A.M., M.D., Professor Chemistry, Physics and Toxicology in the Medical Department, Cornell University. Fifth Edition. Cloth. Pp. 115. Price, $1.00 net. New York: Wm. Wood & Co. 1903.

DISEASES OF THE NOSE AND THROAT. By Charles Huntoon Knight, A.M., M.D., Professor of Laryngology, Cornell University Medical College. 147 Illustrations. Cloth. Pp. 423. Price, $3.00 net. Philadelphia: P. Blakiston's Son & Co. 1903.

A NARRATIVE OF MEDICINE IN AMERICA. By James Gregory Mumford, M.D., Assistant Visiting Surgeon to the Massachusetts General Hospital. Cloth. Pp. 508. Price, $3.00. Philadelphia and London: J. B. Lippincott Co. 1903.

TRANSACTIONS OF THE TWENTY-FIFTH ANNUAL MEETING OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION. Held at Washington, D. C., May 12, 13 and 14, 1903. Cloth. Pp. 292. New York: Published by the Association. 1903.

NURSES' GUIDE TO SURGICAL BANDAGING AND DRESSINGS. By William Johnson Smith, F.R.C.S., Principal Medical Officer, Seamen's Hospital, Greenwich. Cloth. Pp. 167. Price, $0.75. Philadelphia: J. B. Lippincott Co.

HYPNOTISM. Its History, Practice and Theory. By J. Milne Bramwell, M.B., C.M. Cloth. Pp. 477. Price, $4.50 net. Philadelphia: J. B. Lippincott Co. 1903.

TRANSACTIONS OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK for the Year 1903. Cloth. Pp. 514. Published by the Society. 1903.

New Patents.

Patents of interest to physicians, September 1 and 8:

737591. Sanitary face shield. Ellen Dempsey, Albany, N. Y.
738009. Medicine applicator. Julius N. Dews, Portsmouth, Va.
738104. Device for lifting sick people in beds and removing them from same. August Gaiser, Oberndorf, Germany.
737625, 737626. Making sulphuric acid and apparatus for manufacturing sulphuric acid. John B. F. Herreshoff, New York.
737838. Shielded clinical thermometer and making same. Solomon C. Hirschberg, New York.
737656. Vaccine and preparing same. La Fayette R. Parsons, Detroit.
737959. Ankle-supporting shoe. Abraham Posner, New York.
738078. Electric belt for medicinal purposes. Ebenezer Smellie, Glasgow, Scotland.
737795. Syringe pipe. Victor C. Van't Woud, New York.
738593. Auriphone. Lewis M. Atkinson, Rockport, Ind.
738274. Making perfumes and disinfectants. Jean Bardin, Brussels, Belgium.
738283. Spine-stretching device. Carl G. P. Blomqvist, Omaha.
738403. Electrovibratory apparatus for therapeutic purposes. Fred H. Brown, Los Angeles.
738603. Syringe nozzle. Haydn Brown, London, England.
738529. Body brace. William B. Dewees, Salina, Kas.
738680. Sanitary cuspidor. Michael E. Headland, Butler, Pa.
738544. Hot water bottle. Frederick H. Jones, Wakefield, Mass.
738461. Preparing oils for medicinal use. Philipp Lewy, Charlottenburg, Germany.
738339. Bust developer. Sidney P. Madeira and J. J. Purcell, Pueblo, Colo.
738352. Binaural stethoscope. William J. Penfold, Newcastle-on-Tyne, England.
738357. Massage apparatus. John A. Reade, Jr., and C. F. Birtman, Chicago.
738583. Pneumatic massage apparatus. Robert Watson, Scranton, Pa.
738508. Irrigating device. Cora I. Wilson, Philadelphia.

The Public Service.

Army Changes.

Movements of Officers of the Medical Department, U. S. Army, under orders from the Adjutant-General's Office, Washington, D. C., for the week ending Saturday, Sept. 19, 1903:

Ames, Roger Post, contract surgeon, is granted two months' leave of absence.

Geer, C. C., first lieut. and asst.-surgeon, is granted leave of absence for one month, to take effect on the expiration of his present sick leave.

Noble, Robert E., first lieut. and asst.-surgeon, having reported his arrival at New York City, is relieved from further duty in the Division of the Philippines, and will proceed to Fort Sheridan for duty.

Straub, Paul F., captain and asst.-surgeon, will proceed, at the proper time, to West Point, Ky., and report, not later than September 25, to Major-General J. C. Bates for temporary duty during the Army maneuvers to be held at that place, and, on the completion thereof, will return to his proper station.

Wales, Philip G., major and surgeon, is granted an extension of one month's sick leave on surgeon's certificate.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending Sept. 26, 1903:

P. A. Surgeon H. C. Curl, detached from the *New York* and ordered to the *Boston*.

P. A. Surgeon J. S. Taylor, detached from the Bureau of Medicine and Surgery, Navy Department, and ordered to the Naval Hospital, New York City.

Surgeon E. R. Stitt, detached from duty as a member and recorder of the naval and medical examining boards, Washington, D. C., and ordered to resume usual duties.

Surgeon C. F. Stokes, detached from the Bureau of Medicine and Surgery, Navy Department, and ordered to the Naval Museum of Hygiene and Medical School, Washington, D. C.

Asst.-Surgeon A. Stuart, ordered to the Naval Hospital, Naval Home, Philadelphia.

A. A. Surgeon J. L. Taylor, appointed acting assistant surgeon from Sept. 16, 1903.

A. A. Surgeon F. W. Tyree, detached from the Naval Hospital, Port Royal, S. C., and ordered home to wait orders.

Surgeon J. M. Steele, ordered to the Naval Hospital, Port Royal, S. C.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Sept. 25, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, Sept. 12-19, 2 cases.
California: Los Angeles, Sept. 5-12, 6 cases; San Francisco, Sept. 6-13, 2 cases.
Colorado: Denver, Aug. 22-29, 1 case.
Illinois: Belleville, Sept. 12-19, 3 cases; Chicago, Sept. 12-19, 7 cases.
Maine: Brewer, Sept. 17, present.
Massachusetts: Fall River, Sept. 12-19, 3 cases.
Michigan: Port Huron, Sept. 12-19, 2 cases.
Mississippi: Natchez, Sept. 5-12, 2 cases.
Missouri: St. Louis, Sept. 12-19, 1 case.
New York: New York City, Sept. 12-19, 1 case.
Ohio: Lorain, Sept. 12-19, 1 case.
Pennsylvania: Carbondale, Sept. 14-21, 1 case.
South Carolina: Charleston, Sept. 12-19, 1 case.
Washington: twenty counties, Aug. 1-31, 34 cases, 2 deaths.
Wisconsin: Milwaukee, Sept. 12-19, 2 cases.

SMALLPOX—FOREIGN.

Belgium: Liege, Aug. 29-Sept. 5, 1 case, 1 death.
Brazil: Pernambuco, July 17-31, 5 deaths; Rio de Janeiro, Aug. 8-23, 128 cases, 62 deaths.
China: Shanghai, Aug. 1-8, 2 deaths.
France: Marseilles, Aug. 1-31, 11 deaths; Paris, Aug. 22-29, 2 deaths.
Great Britain: Birmingham, Aug. 29-Sept. 12, 5 cases; Dublin, Aug. 29-Sept. 12, 1 case; Leeds, Sept. 5-12, 11 cases; Liverpool, Aug. 29-Sept. 12, 10 cases, 3 deaths; Manchester, Aug. 29-Sept. 5, 2 cases; Newcastle-on-Tyne, Aug. 22-Sept. 5, 12 cases, 1 death; South Shields, Aug. 2-Sept. 5, 5 cases, 1 death.
India: Bombay, Aug. 11-25, 7 deaths.
Mexico: City of Mexico, Aug. 30-Sept. 13, 5 cases, 5 deaths.
Netherlands: Amsterdam, Aug. 29-Sept. 12, 4 cases.

YELLOW FEVER—UNITED STATES.

Texas: Laredo, Sept. 24-25, 2 cases, 2 deaths.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Aug. 8-23, 8 cases, 1 death.
Colombia: Panama, Sept. 7-14, 4 cases, 1 death.
Mexico: Citas, Aug. 30-Sept. 5, 24 cases, 3 deaths; Merida, Aug. 30-Sept. 5, 11 cases; Motul, Aug. 30-Sept. 5, 1 case; Monterey, Sept. 23, present; Nuevo Laredo, Sept. 17, 1 case; Progreso, Aug. 30-Sept. 5, 1 case, 1 death; Tampico, Aug. 30-Sept. 5, 7 cases, 3 deaths; Tehuantepec, Aug. 30-Sept. 5, 2 deaths; Salina Cruz, Aug. 30-Sept. 5, 4 cases, 2 deaths; Vera Cruz, Sept. 5-12, 44 cases, 14 deaths.

CHOLERA—FOREIGN.

China: Amoy, July 15, present; Shanghai, Aug. 1-8, 1 death.
Straits Settlements: Singapore, July 25-Aug. 1, 5 deaths.
Turkey: Syria, Aug. 17, 472 cases, 428 deaths.

PLAGUE—INSULAR.

Hawaii: Hilo, Sept. 15, 1 death; Honolulu, Sept. 11-12, 2 cases.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Aug. 8-23, 31 cases, 22 deaths.
Chile: Conception, July 11, present; Iquique, July 14-Aug. 8, 53 cases, 34 deaths; Pisaqua, July 11, present; Valparaiso, July 11, present.
China: Fuchau, Aug. 12, present; Hongkong, Aug. 1-22, 13 cases, 12 deaths.
Egypt: Alexandria, Aug. 15-21, 8 cases, 4 deaths; Damiette, Aug. 15-21, 3 cases, 1 death.
India: Bombay, Aug. 11-25, 165 deaths.

GASTRIC ULCER;

CLINICAL, PATHOLOGICAL AND SURGICAL PHASES.*

A. H. CORDIER, M.D.

KANSAS CITY, MO.

The invasion of the domain of internal medicine by the modern surgeon has been one meeting no little opposition, as the battle of words in medical societies and articles in journals will attest, yet this onward march of the application of proper surgical principles continues. With true surgical principles applied to internal organs, with actual demonstrations of the results claimed by such procedures by the surgeon, the practitioner is willing to accept these procedures and to recommend them. Only a few years ago pelvic hematocele found a place in every text-book and was treated from a medical standpoint, some cases recovering, but many dying; to-day ectopic gestation with ruptured tube has replaced the hematocele pathology, and proper surgery saves the majority of these cases. Postmortems on cases dead from internal bleeding from ruptured tubes, and surgical operations on the living revealed the true pathology in these cases. The proper management of these cases is understood by every physician and surgeon of to-day.

Nature is a great healer when the conditions are favorable for repair. The whole secret of Nature's reparation of tissues destroyed or injured is embodied in one of nutrition, both bodily and locally, and a physiologic rest of the diseased part. Unfortunately for Nature, there are some parts of the body in which these desired ends can not, in a great measure, be attained. While the stomach is not necessary to life, the being is much better off with than without it. Absolute physiologic rest of this organ is almost if not impossible; thus both the strongholds of persistent pathology are well guarded by impaired bodily nutrition and physiologic activity of the crippled stomach. If an eye is inflamed it is put to rest in a darkened room; if a synovitis exist the joint is immobilized; if there exist an ulcer on the lower extremity, the leg is bandaged and elevated when necessary to give support (physiologic rest) to the crippled returning blood current. If a similar process exist in an internal organ why not apply the same surgical principles for its relief?

Since Billroth's successful pylorectomy in 1881, stomach surgery has advanced rapidly both in perfecting the technic and scope of application. The operations for removal of malignant growths have not been attended by a permanency in their curative results that lends much encouragement, yet the temporary relief obtained has justified this effort at palliation of symptoms and prolongation of life.

In 1881 Wolfler performed the first gastroenterostomy. This operation was devised to relieve cases of malignant and non-malignant stenosis of the pylorus with stomach dilatation, and the results have been all that could be desired in the relief of disagreeable symptoms even where a cure was not possible. The application of this operation to the cure of uncured medicinally-treated cases of gastric ulcer, has more recently been introduced with results that are most satisfactory.

The term ulcer of stomach as applied to this article does not include malignant neoplasms, or the multiple follicular ulceration in tuberculosis of the stomach. The term ulcer does not necessarily imply that there is but one ulcerated spot, as there may be many and yet come within the scope of this article. Of 867 cases reported by one author there were more than one ulcer in 175 of the cases. The acute cases are more likely to be multiple, but of this variety surgery is needed less, save for hemorrhage.

A chronic ulcer of the stomach may be very large or may remain for years a small round ulcer the size of a quarter. The investigations that have been made to determine the location of these ulcers have been so imperfect and haphazard that they are almost valueless. Yet a number of carefully recorded postmortems have shown that certain parts of the stomach are more liable to this disease. On the posterior wall of the lesser curvature near the pylorus is a favorite site for the development of an ulcer. The usual shape of these ulcers is round or oval, yet the large ulcers may assume almost any shape or several may be joined together by an isthmus of healthy mucous membrane. The healing of an annular ulcer may by the cicatrix produce sacculation of the stomach into two or more divisions. Hemorrhage as a symptom is quite prominent at some stages of an ulcer's progress, yet it may be so trivial as not to be of much consequence or value as a diagnostic or operative indicator. On the other hand, hemorrhage from a gastric ulcer is a frequent cause of death. In a large series of fatal cases the postmortems revealed 20 per cent. of death from hemorrhage. This table was based on deaths from chronic cases, as the death rate from hemorrhage in acute cases is very much lower, 5 per cent.

In cirrhosis of the liver ulcers are of rather frequent occurrence, and are prone to bleed, owing to the impeded circulation through the liver. I remember seeing such a case a few years ago. The hemorrhage in this case was terrific. The patient made a recovery and is well to-day, as far as his gastric ulcer is concerned.

* Read at the Fifty fourth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. A. Palmer Dudley, H. P. Newman and J. H. Carstens.

As an ulcer (chronic) approaches the peritoneum it forms adhesions to surrounding organs. The pancreas is most frequently involved owing to the ulcer being on the posterior wall. This mass of adhesions at the time of operation is liable to lead the surgeon into an error in diagnosing the condition as cancer, especially when the omentum is involved. Such was my experience in one case. This effort on the part of Nature to prevent first, perforations into the general peritoneal cavity, and second, to limit local suppuration in case such takes place. The conservative efforts of Nature are often detrimental by obstructive symptoms, and may prevent ulcers healing. The efforts on the part of Nature to limit the pathology occasionally result in a fatal hemorrhage from adjacent vascular organs. Peritonitis may extend over a large area of stomach without perforation, thus limiting movements of the organ and causing contraction of its walls. Delays permit large ulcers to form. Large cicatrices interfere with the functions of the organ, are prone to break down into ulcers again, or to become malignant. A portion of a stomach becoming fixed by adhesions to the liver limits the peristaltic movement and permits the food to remain in the lower segment of the organ; fermentation results, and dilation is inevitable. It is not necessary that the pylorus be constricted in every case of gastrectasis. All are agreed as to the management of these cases.

On first thought one would naturally think that nearly all those cases of extensive chronic ulcers would in their progress divide vessels that would quickly bleed the patient to death, but when we recall the inflammatory changes that have taken place in the surrounding structures and the power of the muscular contractions on the vessels when this change is not complete, it is then easily understood how Nature so frequently checks the bleeding in this locality. There is no way of telling in advance as to how well Nature has fortified against such an attack. The deeper the ulcer the larger the blood vessel injured and the more profuse the bleeding, as a rule. Nature anticipates the dangers of a threatened perforation in many cases by agglutinating some structure or organ to the visceral peritoneum overlying the seat of threatened invasion. If this effort is not successful the contents of the stomach are spilled into the general peritoneal cavity, resulting in death quickly. If success attends this effort a localized abscess may result, or fatal hemorrhage may be induced at time of perforation; especially is this true if the pancreas, liver or spleen should be the organ adhered. The most frequent site of the perforation has been variously located by different observers, the consensus of opinion placing the majority of perforations in the anterior wall of the stomach, which is contrary to the location of the majority of ulcers. When we recall that many cases may perforate in the posterior wall and not be diagnosed owing to the frequency of the limiting inflammatory process protecting the general peritoneum, we can then see how uncertain this theory is. The anterior perforations are the fatal ones, hence postmortem verifications are more frequent. This disease is four or five times as prevalent in women as in men, but the mortality of the latter is much greater than the former. While the general belief has been that this is a disease especially liable to attack young girls, the statistics of some authors rather disprove this theory, showing gastric ulcer occurring most frequently at the age of twenty-five. Simple ulcer is rare before puberty.

As a rule, the ingestion of food produces pain in the cases where there is a freedom from suffering when the stomach is empty, and in those cases where there is persistent discomfort the pain is increased by taking food into the organ. Solid or coarse food is more liable to produce pain. Milk and all mucilaginous drinks, as a rule, rather relieve the pain, in this respect differing from the usual effects of milk in the non-organic conditions. A patient may complain of a pain in the epigastrium over a large area, yet the tenderness may be confined to a small spot.

During menstruation, when the abdominal organs are physiologically congested, the pain in gastric ulcer is increased, and the tenderness is more marked. It has been noticed that the vomiting of blood is most likely to take place and to be more profuse at this period. Vomiting as a symptom is not of as frequent occurrence as is generally supposed, yet in many cases it is the one symptom above all others to be met by treatment. A feature to be remembered about the vomiting is that it is not usually accompanied by nausea, and the vomiting does not require much effort. This vomiting usually takes place in about fifteen minutes to two hours after taking food. The vomitus usually contains an excess of hydrochloric acid. Where there are adhesions to surrounding organs in the region of the pylorus, vomiting may occur at any time of the day or night, regardless of the ingestion of food.

Where there is a catarrhal condition of the whole mucous membrane in these cases the vomiting is more persistent, comes on earlier and is accompanied by more nausea. While the vomiting is Nature's remedy to rid the stomach of the pain-producing foreign substances it at the same time is a dangerous complication, leading to starvation, hemorrhage and rupture of the ulcer. The bleeding in these cases varies from a few undetected drops to a fatal ending. Hematemesis occurs in probably 75 per cent. of all cases, yet an ulcer may be slowly forming for years without giving rise to a perceptible hemorrhage. A hearty meal, a meal of solid food or a gaseous distention may be the exciting cause of an alarming hemorrhage.

In the long-standing cases of pyloric ulcer the vomiting and pain are more persistent, and usually last until a fatal termination is reached. When the ulcer or cicatrix is near the pylorus, the stomach is more liable to be dilated, and parts of its contents remain to become decomposed into a sour, stinking, poisonous fluid. The repeated hemorrhages leave the sufferer with impaired digestion, less recuperative powers, and profoundly anemic—all complications against a successful recovery of the patient.

The dignity of a gastric ulcer is much depreciated by thinking or speaking of it as an abrasion of the mucous membrane of the stomach giving rise to a small painful spot felt in front and behind, with occasional vomiting of blood, these trivials to be relieved by subnitrate of bismuth, nitrate of silver, etc. About 10 per cent. of all gastric cancers have their origin in a benign ulcer (Lebert). If we accept this statement as true we then have a strong argument in favor of resorting to any procedure for the early cure of all benign ulcers of the stomach. Prophylaxis is the keynote of the successful treatment of this incurable disease, when once inaugurated.

CASE 1.—Mrs. P., age 43. Mother of three children. Housewife. American. Three years ago this woman began having dyspeptic symptoms and especially pain after eating. A year afterward she began vomiting soon after meals, from the fact that vomiting gave temporary relief from the pain. The pain usually began a half hour after eating and would last for

three or four hours, or until the stomach was emptied by free emesis. The vomiting at first was only after eating, but within a few months it would come on at any time, and usually nothing but a quantity of ropy mucus was thrown up. She would vomit as many as a dozen times a day. Her nourishment the first six months was good. For the whole time of her illness she had a pain in the epigastrium, the area of same being half the size of the hand, and exactly in the center of the body. This pain has been transmitted posteriorly. Tenderness on pressure has been a marked symptom from the beginning of her illness. For the last six months she has been vomiting considerable blood each day, and recently has had some severe hemorrhages; a quart at one time being the most. At the time I saw her she was vomiting repeatedly during the day and night, and an abundance of blood was present each day. She was much emaciated, and her facial expression was one of pain and "tired-of-life" character. She had a scaphoid abdomen, with hard abdominal muscles. Tenderness on pressure in the hypogastrium was well marked. The stomach was not dilated, in fact, appeared contracted, as the stomach resonance was diminished on percussion.

A diagnosis of malignant ulcer of the pyloric end of the stomach was made and an operation advised for its relief: the procedure advised being a gastrojejunostomy. This operation was performed, using a large-sized Murphy button. The lowest portion of the anterior wall of the stomach was selected as the site for the anastomosis to a coil of jejunum fifteen inches below the pylorus. At the time of the operation an ulcer two or more inches in diameter could be made out in the posterior and upper border of the stomach near the pylorus. Some adhesions to the under surface of the liver could be defined. Her recovery from the immediate effect of the operation was rapid. She did not vomit for two or three days, when she had two slight vomiting spells. At the end of the third day she was taking liquid nourishment, relishing the same and retaining it. In a few more days she was taking solid food, in the way of steak, eggs, etc. During her three weeks' stay in the hospital she did not vomit a dozen times, while before her operation she vomited a dozen or more times daily. Her bowels became regular, her facial expression was completely changed, and her bodily nourishment was materially improved in that time. She passed the button six weeks after the operation. It is now ten weeks since the operation and the physician, Dr. Huffman of Columbus, Kans., writes me: "She is doing well; is able to walk to town, a distance of three-quarters of a mile. She complains of a slight nausea at times, but it is growing less. I think you have had an excellent result and she is well pleased."

Case 2.—Mr. C., age 38, eighteen years ago began having digestive trouble. It was noticed at that time that solid particles of food in the stomach gave rise to more or less pain. A year or so later vomiting began as a symptom. This vomiting was usually produced by the presence of food in the stomach. After the stomach was emptied the pain would cease, and the patient would be fairly comfortable until after another meal. On one or two occasions he had quite a perceptible show of fresh blood in the vomited material. This painful condition continued up to the time of my first examination. In addition to the above history I learned from the patient that large quantities of material would be thrown up that had been retained in the stomach for two or three days. As much as twelve or fourteen pounds of strongly acid, offensive material would be thrown up from the stomach at one time. This usually brought some relief, but even when the stomach was emptied of its solid contents gaseous distention would go on, producing great distress from the pressure of the enormously dilated stomach. Cardiac and pulmonary dyspnea was a very prominent symptom as a result of this pressure against the diaphragm.

He had lost very much in weight at the time I saw him, and weighed only 115 pounds, was taking 20 grains of morphin a day and was in a desperate condition in every sense of the word. My examination revealed an enormously dilated stomach and a very much emaciated patient. There was no tenderness on pressure at any spot over the abdomen; no enlargement or induration could be detected through the thinned abdominal walls. A diagnosis of pyloric obstruction resulting from the healing of a non-malignant ulcer was made. An operation having in view the establishing of a free communication between the stomach and the lower alimentary tract was advised and accepted. It was noticed in the examination that the pylorus was very low and unusually far to the right of the median line. For this reason, at the time of the operation, the incision was made in the right semilunaris, believing that it would give the nearest approach to the most dependent portion of the dilated organ. The correctness of this decision was verified at the operation. I found on opening the abdomen the stomach very much dilated, but in position, as before described. Believing, as I do, that all of these operations should be primarily drainage procedures, the anastomosis was made nearer the pyloric end of the stomach than that usually advised or found necessary. The incision in the stomach was made in its anterior wall, about four inches from the pylorus. A coil of the jejunum 15 or 18 inches below the pylorus was selected as the suitable site for the incision in this portion of the canal. The usual precautions were used in the application of the sutures in the use of the Murphy button.

Fig. 1.—Gastrojejunostomy. Pyloric stricture (S) from healed gastric ulcer. Pyloric end of stomach displaced downward, hence the location of anastomosis (A).

The operation was quickly performed and the patient returned to bed in good condition. Following the operation there was no unpleasant symptom. In a few days he was able to take the necessary nourishment without any inconvenience or pain following its ingestion. The morphin was withdrawn from him, and at the end of three weeks he was not only broken of his morphin habit, but was able to return to his home, taking both liquid and solid nourishment with perfect comfort. He continued to improve until his former good health and weight were regained. He increased in weight until he weighed 180 pounds and was strong and able to do any work that was necessary for him to do. His digestion was perfect and free from pain; the gaseous distention disappeared and the stomach seemingly regained its natural size and tonicity. He continued in this state of health for six and one-half years. He was then taken with acute pneumonia, and within two weeks died as a result of this attack.

I was fortunate in being able to make a postmortem in this case. On examining the stomach I found that there was a complete obstruction of the pylorus (Fig. 1): that the stomach had regained its former size; that its muscles were well developed and in a healthy condition; that the portion of the duodenum and jejunum above the point of anastomosis, while in a healthy condition, showed well-marked evidence of atrophy from disuse. At the site of the anastomosis there was absolutely no omental or other adhesions except those made by the union of the bowel to the stomach. The opening from the stomach into the lower segment of the bowel was as large, seemingly, as at the time of the operation. There appeared to be a species of valvular action that prevented the contents of the stomach from going into the upper coil of the bowel. A similar arrangement seemed to exist preventing the bile from going into the stomach. On filling the stomach with air or water not one drop or bubble could be forced through the pylorus. The water would enter the lower segment of the bowel with perfect ease, but none at all would go into the upper segment until after the stomach and lower segment of the bowel were thoroughly distended.

As remarkable as it might seem, the Murphy button, instead of passing into the intestine and finding its way out into the external world, as is usual, had dropped into the stomach and remained there for nearly seven years, or until the time of his death. Its presence in the stomach had never given rise to a single symptom. One end of the button was very much destroyed, presumably by the secretions of the stomach.

The accompanying illustrations show very distinctly the strictured condition of the pylorus, also the perfect anastomosis between the bowel and the stomach. It also shows the distended condition of the stomach and the lower segment of the bowel with very little distention of that portion of the intestine above the site of the anastomosis.

While the dropping back of the button into the stomach might be used by some as an argument against its use, this objection would certainly lose its force from the fact that not a symptom was produced by its presence, and also from the fact that the time of performing the operation is very much shortened, a no small item in many of these cases. The greatest of all in favor of the button is the fact that nearly every one of these cases recover from the operation if the work is properly done.

This case illustrates a condition following the healing of a gastric ulcer, the scar causing pyloric stricture.

CASE 3.—Mr. S., age 48. Twenty-five years ago this man had quite a severe hematemesis. This was followed by a long period of gastric pain and uneasiness after eating, with occasional vomiting spells. These symptoms troubled him for a number of years, then for several years he was comparatively healthy. About two years ago he began having a burning in his stomach after eating, with an occasional eructation of a sour, foul-smelling liquid. He was troubled from gaseous distention of the stomach and bowels. Constipation was a marked feature. Soon occasional vomiting attacks were noticed and he began losing flesh. He became very much emaciated and cachectic in appearance. He had a long course in gastric lavage and dieting, with no improvement in his general condition. One year ago he left his business (wholesale merchant) and spent several months in the south. During his stay there he gained in flesh, and on his return resumed his former business; but he was soon compelled to stop on account of his old symptoms, returning. He lost thirty-six pounds in five months.

I find on examining him that he is very anemic and much emaciated, with a look of care and uneasiness depicted on his face. I find the tongue coated brown and the breath very offensive. (This has been a feature of his case for several months.) The lower portion of the abdomen is flat and the muscles tense and dry. No gases in the intestines. Stomach distended with gas two inches below the umbilicus. Sense of resistance and pain on pressure in the region of the pylorus. No tumor discernible; vomiting several times each day. No solid food tolerated by the stomach, and practically all liquids rejected after remaining in the stomach for a few hours. Coffee-grounds-looking material is vomited often. A test meal showed: Total acidity, 20; reaction faintly acid; free acid, 0; HCl, 0; lactic acid, small amount. The examination by Dr. Wolf four weeks after operation showed: Total acidity, 75; reaction strongly acid; free acid, 0; HCl, 0.

A diagnosis of probable non-malignant partial stenosis of pylorus was made, resulting in dilatation of the stomach.

The early history of this case was one of gastric ulceration, later a healing of the ulcer, then a reformation of a benign or malignant ulcer at the site of the old scar, with a pyloric stenosis and gastrectasis. Operation was performed on the anterior wall of the stomach at the most dependent point.

Eight years ago I laid stress on the importance of making the opening in the stomach in a position that would act as a drainage opening (Figs. 2 and 3). This case since the operation has been one of continued comfort and improvement. He is taking an abundance of food, and is gaining strength and weight. He has not vomited a single time since the operation; neither has it been necessary to wash the stomach, this being required twice a day before the operation.

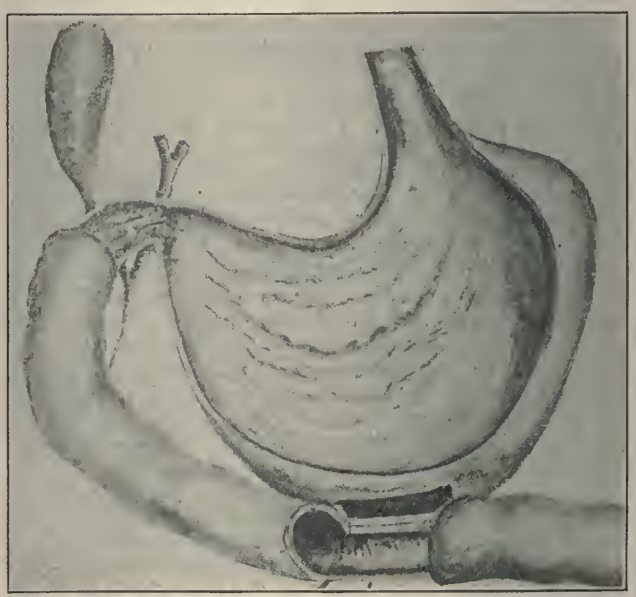

Fig. 2.—Showing that opening should be made in bottom of stomach.

The medical management of 50 per cent. of these cases is quite satisfactory, but I know of no class of cases requiring more patience on the part of the physician, and more faithfulness on the part of the patient in carrying out the instructions.

There is a class of cases where either from want of favorable surroundings or for want of persistent assistance from the patient the medical management of these cases is a total failure. There is yet another class of cases in which, regardless of all faithfully tried remedies, the disease goes on year in and year out, with no indications of a permanent recovery; while there are a class that from the dangerous symptoms induced require some line of management more certain and rapid than the slow expectant treatment usually carried out. For instance: Starvation, severe pain, persistent vomiting and alarming recurring hemorrhages. Of the medical management I will have very little to say in this article, but confine my remarks to the management of this class

where a fair trial of that line of management has been given and failed.

The excision of a gastric ulcer, would, on first thought, appeal to one as the ideal method of dealing with such cases, but when we take into consideration the difficulty of defining the limit of the ulcer, the lowered vitality of scar tissue in its efforts to unite, the extensive adhesions of the bottom of the ulcer to surrounding viscera, and the dangers of hemorrhage and injury to other organs in separating these adhesions, we then can understand why the mortality is so very high in excision of a gastric ulcer. The prime object to be sought in the healing of a gastric ulcer is to maintain the health standard by proper nutrition, removing all sources of irritation possible, giving the parts rest. How are these ends best obtained? In the rebellious cases where the uncertain nutrient enemas can not be carried on for the proper time, and where the liquid diet will not be adhered to, where there is persistent pain, alarming hemorrhages,

Fig. 3.—It is not necessary to do multiple operations.

or where the patient is so situated that he or she can not afford to wait on the slow, uncertain, hard to carry out, and expensive medicinal method, there the case becomes a strictly surgical one. A gastroenterostomy fulfills or meets most of the indications in such cases. By selecting a site for the anastomosis in the most dependent portion of the stomach, the organ will empty itself by gravity as soon as any food enters it; thus getting rid of this source of mechanical irritation. At the same time the strongly acid secretions of the stomach are drained into the intestines and away from the ulcer. If efforts at vomiting should occur the stomach empties itself into the bowel through the non-valvular opening, and thus the nourishment of the body is maintained and the proper healing augmented by an increase of the reconstructive systemic powers. The motility of the diseased organ is best limited by this procedure and the ulcer permitted to have rest, so necessary in the healing of an ulcer, regardless of its location. The putrefaction of the retained food in the cases with a gastrectasis is prevented and the distention of the organ from the gases averted, thus permitting a contraction of the edge of the ulcer, and preventing the tension of the same that may lead to increased pain or a hemorrhage.

The mortality in a gastroenterostomy is very low in skilled hands, and the relief of symptoms and cure of the ulcer is to be expected in the great majority of cases.

DISCUSSION.

Dr. J. H. Carstens, Detroit—I endorse what the essayist says and to add that in these cases of pyloric obstruction from other cause, where there seems to be a simple contraction, operative correction is simple, but I do not believe that I would put in a Murphy button and leave it there for six years. I use the McGraw ligature, which is simple and can be inserted quickly, and there need be no fear of brass poisoning.

Dr. John G. Clark, Philadelphia—Two points occur to me: 1. How long shall these cases remain under medical care before being subjected to surgical interference? 2. How shall one best and most quickly locate the ulcer? Because a considerable proportion of cases of gastric ulcer will heal spontaneously under careful medical treatment, precipitate operation is unwise. Only after the case has been carefully treated for a sufficient time to determine its chronicity, or when urgent symptoms, such as peritonitis or excessive hemorrhage, occur is it wise to operate. In several instances I have advised a waiting policy, even when the symptoms were rather exaggerated, and thus far I have had no occasion to regret this course. When, however, through its chronicity, or, as said above, through threatening symptoms, the patient's life is seriously jeopardized, an operation should be performed. The second question then comes up for consideration, how best to find the ulcer? Unless the pathologic process is chronic, associated with induration and superficial evidences of inflammation, it may be difficult or impossible to locate by palpation the exact site of the ulcer. Again, if the ulcer is situated on the posterior aspect of the stomach, adhesions may have taken place, making it difficult or impossible without great danger of dislocating the stomach, to bring it into the field of operation. It is, therefore, wise in these cases not to lose time in searching in this more or less haphazard and superficial way, but to make an immediate exploratory gastrotomy. The less vascularized portion in the anterior wall of the stomach, situated between the lesser and greater curvature, should be selected as the site for this exploratory incision. When the incision is made it need not necessarily be a large one. Not only may the stomach be efficiently palpated, but actually inspected. A small speculum or tractor may be inserted into the incision, and in one instance I was able to locate the ulcer with a small electric light. When the ulcer is located in the posterior wall and is bound down by adhesions, it is not wise to break up these adhesions, for the edges of the ulcer may be sufficiently pared and sutured directly through the incision. This is by all means the safest method, and is in direct accord with the method of suturing described by Connell.

Dr. C. O. Thienhaus, Milwaukee, Wis.—When one of the larger arteries of the stomach is eroded by the ulcer, the hemorrhage is usually so severe that the patient succumbs before there is a chance for operation. In regard to other cases of acute hemorrhage I would warn against immediate operation. One may observe patients with severe hemorrhage and anemic to such a degree that one believes nothing but surgical interference can save his life, but usually the patient recovers by proper internal treatment, while operation is extremely dangerous and the mortality, as statistics show, enormously high. For this class of cases, as well as for hemorrhage from typhoid ulcer, I highly recommend gelatin, either by mouth or rectum. I would not like to go on record as claiming gelatin to be a panacea for internal hemorrhages; but, as above cited, it is of great value and ought to be given a trial before taking the responsibility of operating in the acute stage of hemorrhage. I would like to ask Dr. Cordier whether, when he uses the Murphy button, he makes use of the generally employed purse-string suture, or does he, after having made the smallest incision possible and having inserted the button,

use only one suture in each corner of the transverse incision, a method which has been highly recommended lately. In regard to pylorectomy versus gastroenterostomy in cases of ulcer of the pylorus, when the patient is over 40 and has been suffering for a long time from a chronic ulcer in this region, I always prefer if possible pylorectomy because many of these chronic ulcers about this age show a tendency toward malignancy and the differential diagnosis is sometimes extremely difficult even during operation, whether the ulcer is still benign or malignant.

DR. F. F. LAWRENCE, Columbus, Ohio—Too little attention has been paid to the point that there is a stage of acute danger in gastric ulcer—the danger of perforation. If there be one condition more than another in which abdominal surgeons should urge the abandonment of medical treatment and the institution of more radical measures, the closing up of the lacerated surface, it is that of gastric ulcer.

DR. CORDIER—I would not advise, in the majority of instances, to operate during the hemorrhage. In fact, you rarely see one of these cases during an alarming hemorrhage. It is remarkable how cases seemingly nearly bleed to death and then recover. These cases are desperate and the thing to do is to operate and to operate quickly. An operation extending over thirty or forty minutes will prove fatal in the majority of cases. My preference is the Murphy button; the establishment of an anastomosis and doing it quickly, using a purse-string suture, completing the operation in fifteen minutes. I use the button in the anterior wall. Many have recommended opening into the posterior wall, but this is not necessary. It makes the work look bulky and as if done by a tyro. The main thing is to make these operations drainage operations; make the opening in the bottom of the stomach, or otherwise you will have the accumulation and decomposition of food and a renewal of the old symptoms. If you make the opening in the bottom of the stomach the food passes right through. The patients can not vomit, and if they do the vomit goes through the intestine and not up through the esophagus.

HYGIENE OF YOUNG GIRLS.*

J. H. CARSTENS, M.D.
DETROIT.

The hygiene of young girls has been discussed and written about so much that it is utterly impossible for me to say anything new or even to present the subject at a little different angle than you have looked at it before.

When I speak of young girls I naturally mean during the age of puberty. We can divide the subject into mental and physical. The hygiene of the body is comparatively easy if the young girls are raised in a primitive state of civilization. Still, again, here there is a great difference. In some of the primitive races, as with certain tribes of Indians, girls have to do hard work, and do not grow up unrestrained as they do among some other primitive people. In the South Pacific islands, for instance, where they grow up without care and restraint, romping, playing, swimming, there they develop even muscular figures and healthy bodies.

This we can not do in civilized communities. As they grow up, some of the children in Europe, for instance, are obliged to carry heavy burdens and do hard work with poor food. They may be muscular, strong and have large bones, but they do not have handsome and graceful figures nor the intellectual training which we desire.

You take, however, our own so-called better class, who have chances for physical development. In New England, where everything is esthetic and where the mental training is beyond the brain capacity, we find just as lamentable a state of affairs in another direction, yes, even worse than we do with the overworked peasantry of Europe.

What modern civilization desires is an even development of the body and mind. This is a very difficult problem, as we have to contend with a long train of ancestors and their hereditary defects in one direction or another. It is not necessary for me to go into the old question of heredity in its relation to rheumatism, gout, tumors, tuberculosis, and so on. I want especially to dwell on the hereditary predisposition of the nervous system. Insanity, alcoholism, epilepsy, and the like, I need hardly dwell on them, as they are so well known. When, however, we have to deal with that condition we call neurasthenia and hysteria, it is very difficult. Naturally, as a rule, it is the mother who transmits this, and by her lack of mental balance strengthens and intensifies this condition in her daughter, and if the father is also weak and soft, and permits and encourages this state of affairs, it is a very difficult thing indeed for us to manage such cases.

The constant suggestion of the mother has its effect on the daughter, and she is finally imbued with the thought that she is nervous and can not help it. All our efforts to improve the condition are negatived by the mother with the statement, "Oh, she can not do that, I never could either when I was her age. She is too weak, my nerves were too weak also," and so on. We might just as well give up unless we can get the young girl away from home and put her under different surroundings. She must be entirely taken away from the influence of the mother and have the care of a trained nurse, who will teach her and who, by constant suggestions in another direction, can show that she is not nervous, not so weak and delicate as her mother thinks. And in the course of a few years a wonderful change can take place. Again, there is the mother who constantly suggests, month after month, that there must be something the matter with her daughter, with her menstrual function, until it is impressed on the young girl's mind that there really is some trouble, and she will always think in the future that her pelvic organs are weak. So I could go on with numerous other points.

If we now turn and go to the opposite extreme, among the poor and poverty-stricken, we find that children are made to work very hard, to carry burdens, to lift their little brothers and sisters, perhaps have improper food, and thus often produce injuries of all kinds, rupture, curvatures, chlorosis, etc.

Ignorance on the part of the mother is very frequently the trouble. In all these cases it is the mother that must be treated. We must get her to understand that we must reform her, and show her how to properly treat, manage and train the daughter so she will grow up strong and healthy. And in nearly all cases with the right kind of argument and teaching we can get the mother's mind so stirred up that we will have comparatively little trouble in managing these cases properly.

This class of young girls must often work at quite an early age, and we should regulate the kind of work that each one is capable of doing. Fortunately a great deal is being done by the state in the enactment of laws regulating the lines of work. These kind of laws should be encouraged, as they tend to improve the health of the young girls. First, in regulating the hours of labor. Secondly, proper ventilation. Thirdly, in proper toilet facilities. Fourth, in the opportunity of getting food at proper intervals.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. A. Palmer Dudley, H. P. Newman and J. H. Carstens.

This brings us to the question of physiology. In all these cases, rich or poor, we must regulate diet above all other things. Medication also sometimes will be required, but comparatively little. The various gymnastic sports should be encouraged, but regulated by the physician. This is the only way we are able to reach some people and make them take the necessary exercises. The one trouble with most of these are that they are lopsided, will develop only certain parts of certain muscles and parts of the body, while it is so essential to have a systematic and symmetrical development of the body. We are not always able to reach our ideals with stubborn and selfish patients, but we must do the best we can and always strive for it.

Trying, therefore, to guide the young girl to strong and vigorous motherhood, it is not necessary to pay any attention to the menstrual function. That will come without trouble unless there are organic defects and changes which will have to be looked after and remedied, but that does not concern us here.

If we now consider the mental development we have the greatest difficulty. If their physical weaknesses are marked, the mental training should cease or be checked. In this we will have comparatively little trouble. The rich will be willing to do so because they seem nearly always anxious to stop their studies or postpone them on the slightest provocation. This holds good especially with the so-called shoddy. With the poor and the middle classes we shall have out greatest trouble. If the young girl has been animated by ambition to be something in the future, to be able to support herself, and perhaps often to assist her parents and younger brothers or sisters, we will have a very difficult task if such a person is physically weak. If we allow her to go on with her mental work her physical condition will probably become still worse. She is liable to have an undeveloped uterus and conditions of the system produced by it; poorly developed lungs, weak heart and arteries, flabby muscles, feeble digestion, malnutrition of the nervous system and final collapse. The latter sometimes they will become when the goal is reached for which they struggle: the diploma, the teacher's certificate or whatever it may be. She has a mind educated for requirements of that position, and a body feeble and weak, and if she marries she will be a burden to the poor husband, in fact ultimately will probably be divorced or a subject to a series of operations, which will be done to remedy her defects.

One of the greatest difficulties is that these people learn with difficulty. They have not the right kind of brains; they have to study hard until late at night to get their lessons. This intensifies and hastens the physical downfall. Such persons should stop mental work for a year or two and do some other kind of work. When the body is more developed they can resume their mental efforts. They often object to this, but we can manage them all right if we insist on it. People with the right kind of brains and quick perception can continue studies and with a proper amount of physical training they will get along all right.

The question of age in all these cases cuts no figure in my opinion. Either mentally or physically some girls are further advanced at 12 than others at 18.

In conclusion, let me say that hygiene of young girls is one of the most difficult problems for the gynecologist to solve. There are no mathematical problems, no rule that is even elastic within a certain limit, but every case almost is absolutely distinct and requires to be studied by itself. The hereditary predisposition, the surroundings, the future course, the position in life, the means at their disposition, the development of the different parts of the body, or the lack of development of certain parts, the assimilation and elimination of the various organs, the brain and the kind of brain, how it should be developed in one direction or another, and a thousand and one things must be considered in each individual case. Added to this there must be that fine tact and that absolute control over individuals, so that we can not only manage the young patient, but also those around her, be it the mother, father, sister, cousin or aunt. We must get them all under our control ere we can expect to accomplish anything.

We are able to teach the students but very little. We can give them a few hints, but the cases are so diverse and complicated that every medical man must work out each case for himself.

PELVIC DISEASES IN YOUNG GIRLS.*

FLORUS F. LAWRENCE, M.D., D.Sc., LL.D.

Clinical Lecturer, Diseases of Women and Abdominal Surgery, Starling Medical College; Chief of Staff and Surgeon to Lawrence Hospital for Women; ex-President Central Ohio Medical Society; ex-Secretary Section on Obstetrics and Diseases of Women, American Medical Association.

COLUMBUS, OHIO.

The popular prejudice against examination of the genital and pelvic structures in young girls is not confined to the laity, but, unfortunately, exists in the minds of many of the medical profession. There can be no question that on this altar of prejudice many otherwise useful lives have been sacrificed. The voice of this Section raised in protest will bring fruitage in healthier women, happier wives and more devoted mothers.

First.—The young have, with those older, an equal right to relief from suffering and an equal right to protection from diseases which destroy their usefulness and may endanger life.

Second.—Many, if not all, diseases of the pelvic structures are, in their incipiency, curable without recourse to operations which sacrifice important organs or parts.

Third.—Delay in recognition of, or correction of even the simpler conditions, such as displacement of the uterus or ovaries, may, and too often does, result in such organic change as permanently to destroy all function and render the patient an invalid, forever sterile.

Fourth.—The symptoms, pelvic pain, menstrual pain, menstrual irregularity, neurotic explosions, digestive disturbances, etc., occurring preceding, during or following the menstrual effort are only warnings and strong hints for us to seek the cause.

Fifth.—That the pelvic conditions of the young girl can be discovered by feeling the pulse, examining the tongue, and looking wise is no more true than it is in older persons.

Sixth.—A certain amount of modesty and respect for traditional sentiment is probably a protection to the sacredness of woman's chastity, but a chaste life is no way incompatible with an honest purpose in dealing with diseased conditions, and no man will, by an honest, clean, manly effort to discover the cause of suffering, excite impure or degrading thoughts.

Seventh.—We must remember that not only the physical, but the social, the domestic, and even the moral, life of the patient is involved in this question. She may, because of our neglect to ascertain the condition,

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. A. Palmer Dudley, H. P. Newman and J. H. Carstens.

be rendered hopelessly sterile, and, consequently, that unhappiest of human beings, a childless wife.

Eighth.—Our first duty, then, should be the protection of the physical temple of those entrusted to our care. A sound physical organism is, I take it, the surest protection against moral degradation.

Symptomatology is sometimes very misleading, inasmuch as the entire history and symptom-complex, as gathered from patient or her mother, direct attention entirely to the nervous system, circulatory system, or digestive tract with the single exception that the disturbances develop at or about the time of puberty.

The most common and probably the most important of the symptoms presented, when rightly interpreted, is menstrual pain. Menstrual pain is not a disease, and should never be so considered. It is but a symptom. It probably is never a condition which has not a definite pathologic cause. These causes may be:

- Pelvic
  - 1. Uterine
    - a, Displacements.
    - b, Infantile uterus.
    - c, Metritis.
    - d, Uterine fibroids.
  - 2. Intrauterine
    - a, Endometritis.
    - b, Uterine polypus.
    - c, Submucous fibroid.
  - 3. Ovarian
    - a, Chronic ovaritis.
    - b, Prolapse of ovary.
  - 4. Tubal
    - a, Septic salpingitis.
    - b, Catarrhal salpingitis.
- Extrapelvic
  - Neurasthenia.
  - Anemia.
  - Chlorosis.

I have offered this arrangement of the causes of menstrual pain because I believe the older classification of obstructive, neuralgic, ovarian, tubal and membranous dysmenorrhea has too much tendency to mark this symptom as an entity and thus prevent the proper study of its cause. Many cases in which the pain is agonizing present absolutely normal pelves. These are the cases in which everything depends on care and patience, and they are of such import as to merit consideration apart from those which have a pelvic cause.

Of the pelvic causes, first, displacement, *per se,* is of the least import. A displacement of the uterus does not in itself give rise to menstrual pain, the old theory of obstruction being untenable.

The pain in these cases is due to the resulting inflammation of the uterus, tubes or ovaries; or if it be an old displacement we may have adhesions. The cure of these depends, of course, on the correction or removal of the pathologic lesion causing it, as, in fact, it will in all cases; but I would emphasize that the displacement, while a primary, is the smallest factor in the case.

In the infantile uterus the entire effort at preparation of the mucosa for fecundation and menstruation is abortive. In many cases menstruation never occurs, or, when it does occur, it is not a free or natural effort. It is an attempt on the part of Nature to prepare an organ for a function to the fulfillment of which it is totally inadequate. First, the mucosa is only partially developed; second, the stroma of the deeper layer of the mucosa and that of the superficial layer are one, and in almost embryonic condition. The only cure is to be found in such measures as will develop the uterus (an almost hopeless undertaking except the girl marry and become pregnant) or in the removal of the tubes and ovaries.

In metritis we have a prolific cause. The explanation is, first, irritation of uterine ganglia causing expulsive contractions; second, pressure on pelvic vessels in the deeper portion of the mucosa, which prevents leucocytes reaching the superficial portion, retards the amyloid degeneration in superficial mucosa, and results in more or less destruction of mucosa. This I believe to be the true cause of that distressing condition known as membranous dysmenorrhea, only in these cases the results are all extreme. In endometritis we have predominating a glandular inflammation; the glands enlarge, crowd each other, press the superficial layer into a smaller space, obstruct the superficial capillaries and retard amyloid or hyaline degeneration; the capillaries in the stroma become congested, rupture, pour out their blood, form lacunæ, and literally tear the epithelium from its moorings. This is probably the condition in which the older writers thought there was some obstruction in the cervix, and because dilatation brought relief, gave it the name of "obstructive dysmenorrhea." In these cases due to metritis or endometritis, no permanent benefit can be expected from any method of constitutional treatment. The local condition must be relieved by curettement, or in some cases by judicious local treatment, and here let me emphasize that we should impress on the minds of the profession that curettement is by no means a minor operation, considered from a standpoint of safety. The hand that wields a curette should be capable of any operation which demands skill, guided by that judgment which can and will recognize the existence of pus in the tubes or other intrapelvic structures, for the reason that curetting in cases complicated by pus tubes is a most hazardous operation. The general condition demands most careful attention. More harm is done these women by tinkering, or inefficient local treatment, than by letting them alone. In the majority of cases the curette, rest for two weeks in bed, general tonics and the correction of constipation will accomplish a cure when local applications may, and often do, result in placing the case beyond hope of relief by simple measure.

Uterine fibroids and uterine polypi cause menstrual pain by mechanical obstruction of the pelvic vessels and compression of the pelvic nerves. The cure lies in their removal, or the artificial menopause by the removal of the tubes and ovaries.

Fibroma can not be considered common in young girls, but that a fibroid may be the cause of very serious trouble is shown by the following case:

Miss J. F. E., aged 15½ years. First seen Jan. 14, 1902. Menstruated first at 12, very profuse and lasting six days, accompanied by severe menstrual pain throughout. Has menstruated every three weeks since until past four months, during which she has menstruated every two weeks. Suffering has lately become intolerable. Two years ago noticed a hard, non-sensitive lump to left of median line, low down. This has grown slowly. About three months ago noticed a dull aching in left loin, and a few weeks later a sensitive lump just below left ribs. Examination revealed what was apparently a myoma developing to the left side of the uterus between folds of broad ligament; another mass, which was indistinctly fluctuating in region of left kidney. Operation disclosed a fibromyoma pressing on and occluding the left ureter, with a resulting hydronephrosis and hydroureter. A myomectomy resulted in complete relief of all symptoms.

Salpingitis is a fruitful source of menstrual pain. In the majority of these cases we have simply the result of a neglected endometritis, i e., the inflammation has extended from the uterus to the tubes. It is suppurative or non-suppurative. The suppurative, although the more dangerous to life, does not give rise to severe menstrual pain until adhesions have formed as a result of peritonitis. That form which is an extension of a catarrhal endometritis results in early occlusion of the tubes, hyperplasia of both the tubal mucosa and mus-

cular wall of the tube, venous engorgement of the tubes and ovaries, and a varicose condition of the ovarian veins. It is in this condition we find the most pronounced premenstrual pain, which is relieved in a few hours after the flow is established. Here the preceding and accompanying endometritis is an important factor. The timely use of the curette will prove our best aid. Let me here urge the necessity of determining the absence of pus tubes before resorting to the curette; for the operation of curetting, when pus tubes exist, is fraught with greater danger than is the removal of the tubes. There is a form of inflammation of the fallopian tubes which occurs as a sequel to the exanthematous diseases. It is usually bilateral, and is nearly always complicated by peritonitic adhesions. The pain is severe at menstrual epochs and resists all forms of local or general treatment.

The consideration of those cases which have an ovarian cause will involve the relation between ovulation and menstruation; a subject too great to be discussed in a short paper. For our purpose it is enough to remember that each month the uterine mucosa develops preparatory to the reception of a fructified ovum, and when that ovum is not impregnated degeneration with rupture of superficial vessels and denudation results in menstruation. Intermenstrual and premenstrual pain can always be attributed to the tubes or ovaries. When to the ovaries we must determine whether it be hyperemia or ovaritis.

Ovarian hyperemia is a common cause of menstrual pain in young girls. Its cause being excitement and ungratified sexual desire, it is apparent that treatment should be such as to direct the patient's thoughts from the genital organs. A change in the social and domestic habits is of prime import. The importance of relief is emphasized by the fact that if unrelieved this condition soon results in chronic ovaritis, hyperplasia, increase of fibrous tissue and complete destruction of the ovary. In the latter condition the pain becomes more severe, more prolonged, and its cure involves the removal of the organ. It matters very little whether the form be cystic, interstitial or hyperplastic, except that the pain in interstitial ovaritis is most severe, while in the cystic we are most likely to find prolonged or profuse flowing, and in many cases intermenstrual hemorrhage. The treatment of any form of chronic ovaritis is too often disappointing and requires for permanent cure the extirpation of the diseased ovaries.

In all these cases the temptation to give opium is great and should be religiously resisted; for so sure as we give it we will make an opium habitué of our patient. In prolapse of the ovary the pain is due to the resulting inflammation of the tubes and ovaries, with the consequent congestion of the entire pelvic contents. There is no method of mechanical treatment which will correct the displacement. Two operative procedures are available: First, if the ovary be not too much affected we can lift it up and secure it by shortening the utero-ovarian ligament, or stitch it to the broad ligament. Second, if the ovaries are diseased beyond repair we can remove them. The power of repair is so great that I am inclined to think we can save a very large percentage.

There is a class of cases in which no disease of the pelvic organs can be detected, and yet the suffering is as severe as in those in which inflammatory trouble exists. These comprise neurasthenics, in whom there seems to be a constant tendency to explosions of all sorts; patients who are anemic or chlorotic. The occurrence of menstrual pain in those subjects is readily appreciated if we keep in mind the utero-ovarian nerve supply and the physiology of the sympathetic. The nerve supply of the uterus, fallopian tubes and ovaries is largely from the sympathetic, with a few fibers from the second, third and fourth sacral. The sympathetic fibers are from the inferior hypogastric and the spermatic plexuses. The hypogastric is a branch of the aortic plexus, which is derived from the semilunar ganglion and renal plexus on each side. If we remember that these sympathetic centers supply branches to all the abdominal viscera, and then keep in mind the fact that irritation or stimulation of a sympathetic nerve causes contraction of vessels, lower temperature, diminished nutrition and increased tissue waste in the parts supplied by it, the increased tissue waste causing increase of carbonic acid gas in the blood, which adds to the irritation, it is not hard to understand how a neurosis may have, as one of its symptoms, painful menstruation. Particularly is this true if we keep before us the facts of the normal menstrual process, viz., that there is, first, an increase of cell growth; second, multiplication of the stroma nuclei and hyperplasia of the superficial mucosa; third, widening of interglandular and intervascular spaces from hyperplasia; fourth, occlusion of capillaries, degeneration and rupture of smaller vessels, and finally, complete denudation of the uterine mucosa. Neither is it hard to understand how these physiologic processes may become abortive as a result of malnutrition in anemia and chlorosis. Great care is necessary in these cases that we exclude local organic disease, for, if there be an endometritis or other evident local inflammation occurring in these neurotic and anemic cases, I do not believe we ever accomplish any good by constitutional treatment alone, and they are certainly not to be operated on. That there are cases of nervous disease dependent on pelvic trouble we all know. The failure to discriminate between those in which the pelvic disease is the cause of the nervous symptoms, and those in which the neurosis is the primary affection has done much to retard the acceptance of operative assistance, by alienists. I would emphasize the statement that operative measures can not be expected to relieve nervous symptoms except when adopted for the removal of distinctly diseased organs, to the condition of which the nervous symptoms may justly be ascribed. On the other hand, I have seen some marked neurotic conditions relieved without further treatment by the removal of diseased ovaries and tubes, or the plastic repair of an enlarged and indurated cervix.

That a leucorrhea always is a symptom of disease of either external or internal genitalia should be kept in mind. That the cause of leucorrhea may be any one of several serious conditions should demand thorough investigation in every case, whether young or old. Tuberculosis of the genital organs is by no means so rare as has formerly been taught and may be the cause of leucorrhea in very young girls. Gonorrhea, with all its frightful sequelæ, I have seen in a number under the age of 15 years, and in two cases under 8 years. Herpes genitalis may occur at any age and gives rise to profuse discharge. Traumatism may be a factor of leucorrhea in some cases. The fact is no patient who has leucorrheal discharge should be treated in any manner whatever until the cause has been determined with reasonable certainty. Profuse and irregular menstruation may be symptoms of such grave import that it would seem scarcely necessary to insist on these cases being thoroughly examined were it not for the fact that we are continually confronted by the statement, made appar-

ently in good faith by active physicians, "that uterine hemorrhage in young girls only needs iron and bitter tonics to cure it." We can not determine whether the cause be metritis, endometritis, polypus, fibroids, cystic ovaries or sarcomata, except by a painstaking examination, and as any one of these may be the cause it is our plain duty to determine which it is. It is equally our duty as gynecologists and as teachers to impress on the minds of our students and the profession, that it is more important to learn how to thoroughly investigate and diagnosticate these cases than to see us operate, or to listen to a description of technic.

SUMMARY.

1. All cases, whether in young girls or in older women, in which menstrual pain, intermenstrual or premenstrual pain is a prominent symptom should be subjected to careful and thorough examination to determine its cause.

2. No leucorrhea should be permitted to pass unnoticed or treated by such "slipshod" methods as ordering a douche, giving medicine, etc., without first ascertaining its cause. In all cases where discharge is purulent a microscopic examination should be made to determine presence or absence of gonococci, tubercle bacilli or other important septic organisms.

3. All cases of excessive flowing, intermenstrual hemorrhage or prolonged menstruation should be thoroughly examined.

4. In all cases where amenorrhea exists every effort should be made to find the cause.

5. In young girls subjects of neurotic symptoms which develop at puberty or occur with each menstrual epoch, a careful and thorough examination of the pelvis will often reveal the cause.

6. If menstrual pain, irregularity, leucorrhea and neurotic disturbances follow the exanthemata, a pelvic examination is imperatively demanded.

7. In all virgins the rectobimanual examination should be used—the vaginal touch only being used when absolutely necessary.

DISCUSSION

ON PAPERS OF DRS. CARSTENS AND LAWRENCE.

DR. L. S. MCMURTRY, Louisville, Ky.—This subject has been greatly neglected by the Section, but has been discussed at length in the special societies. It is a common occurrence for the gynecologist to see young girls whose health has been wrecked by that complex condition known as neurasthenia, when all of the trouble could have been avoided. These young girls pass from one practitioner to another without getting any relief; from the general practitioner to the oculist, and then to the gynecologist, and many finally go to the neurologist. These cases should receive proper attention from the gynecologist, and there is as much to be done by withholding local treatment in many instances as in giving special treatment in other cases. There seems to be a prevailing idea that any young woman who has a disturbance of nutrition with anemia, associated with nervous symptoms, must at once be regarded as possessing no other organ but the uterus, and the treatment instituted in the majority of cases is local rather than systemic. If we could institute some system, and I take it that that is Dr. Carsten's idea, that will be applied by the family practitioner and also by those engaged in special lines of practice, that will early arrest this condition which we call neurasthenia, which will alter the mode of life, environment and education, it would be one of the greatest advances made in any branch of therapeutics. There should be that co-operation between the family physician and the gynecologist that will ensure a sufficiently accurate selection of cases that require local treatment. But the patient should be protected from unnecessary operations and local treatments. Every one engaged in gynecologic work has a large number of these cases come to him, and up to the present time they are certainly among the opprobia of our art. They are usually referred in some other direction and do not receive that accurate therapeutic attention they deserve.

DR. HANNAH M. GRAHAM, Indianapolis—The general practitioner frequently is too careless in making a diagnosis. For instance, I treated for gonorrhea a girl of 14, a child of one of the best families in the state, who had been under the care of a general practitioner for six weeks when her mother brought her to me saying that she had profuse leucorrhea. The physician's treatment consisted of a tablet every three hours, which gave no relief. The mother objected to an examination of the child, but I finally convinced her that it was absolutely necessary. I found that she had gonorrhea, probably contracted from the maid who took care of the children. It is better to examine one hundred girls who have not gonorrhea than to overlook one that has. We find many girls of 14 suffering from dysmenorrhea due to a retroversion or retroflexion, which can be corrected with a three months' tampon treatment. Why let it go on until it requires suspension or an Alexander operation just because she had not reached the right age? Whenever you find disease you have reached the age to treat it.

DR. G. BETTON MASSEY, Philadelphia—I think it is proper for this section to dwell on such matters. We should endeavor to work out plans for the practical application of the hygienic measures suggested. The fault in the imperfect development of many young girls lies in the mothers, in their housing, in over-clothing, and in their becoming over-finicky. It is hardly appropriate here, but in every section of the Association we ought to condemn the wearing of wool underclothing. In my opinion this is one of the most detrimental things that human beings do; the possibility of catching cold when the girl arrives at puberty is greatly aggravated by abolishing skin action by covering the body with an external skin of non-absorbent woolen material. Girls who spend all their time in the open air lightly clothed and taking plenty of exercise will not go to the gynecologist or neurologist. In the suburbs of Philadelphia the number of healthy girls is very great because an athletic life is fashionable. We can accomplish reform only with assistance of Dame Fashion herself. I agree that examinations are necessary when conditions do not yield to treatment, but I do think that many unjustifiable examinations are made in the clinics. Many young girls are examined when their bowels alone are abnormal; examinations are needed only in the case of girls who are suffering from septic conditions, such as a purulent leucorrhea, or from the manifest presence of a neoplasm.

DR. C. L. BONIFIELD, Cincinnati—I heartily agree with everything Dr. Carstens said, and many things that Dr. Lawrence said, but with the side of the subject that seems to be very popular I am not in accord. I have seen cases that would have been much better for an examination, but these are the exceptions. I believe that there are hundreds of girls going to the office of the gynecologist who have no right to be there. They should be treated by the family physician. The symptoms that are referred to the pelvis are of constitutional origin; and if these girls are treated in the proper way, as Dr. Carstens suggested, if their general health is improved and the development of the uterus is encouraged by forcing nutrition, these symptoms will disappear without any local treatment whatever. Of course, there are cases that require an examination. These are the cases where the symptoms are unusually severe; cases that do not yield to the treatment I have mentioned, but I believe that they are greatly in the minority. When such a case comes to us for examination shall we proceed in the way Dr. Lawrence suggested, make a recto-abdominal examination, which is always more or less unsatisfactory; or give the patient an anesthetic and examine carefully so as to arrive at a correct diagnosis? I take it that the objection to examining young girls is not the destruction of the hymen, but it is the shock to the modesty of the young girl. She is subjected to a treatment of which she really should know nothing. Her attention is called to organs of which she should not think at all.

In the majorty of cases if they need an examination they also need operative treatment, and while they are under the anesthetic the little operation, which is usually a curettage, can be done. The objection to local treatment is overcome; our diagnosis is accurate, and we have done the very best we can do for our patient. I believe that if an examination is necessary at all in a young girl it should be done under an anesthetic.

Dr. J. H. Carstens, Detroit—Dr. Bonifield has said all I want to say. If the young girls are let alone and live a natural life, they will not require the gynecologic finger nor much medicine. What they need is physiology. They should get their eliminative organs into good condition so that they do not absorb excrementitious matter. Get the stomach into good condition, make good blood, and, if they have a little leucorrheal discharge, that will take care of itself. If they are a little nervous they will get over it. This gynecologic tinkering and the giving of all kinds of medicines without any indication for it is going too far. When they have well-marked symptoms of dysmenorrhea and a purulent vaginal discharge, then they should be examined and it should be done under an anesthetic. What I plead for is more simplicity, more physiology, and less medicine and fewer specula.

Dr. F. F. Lawrence, Columbus, Ohio—Dr. Bonifield's statement as to cases going to the gynecologist's office that do not belong there is true in many cases; but I would ask the members of this section whether it be proper or improper to have a thoroughly competent oculist examine a patient whose vision is failing as a result of chronic Bright's disease, to determine whether or not there is albuminuric retinitis. So far as the treatment of the case is concerned, it belongs to the general practitioner, but how many of us gynecologists, surgeons or general practitioners are competent to make a diagnosis of albuminuric retinitis? This is equally true in gynecologic work. Those men who have had the experience and the training are the men to make these examinations. The treatment of the patient can be carried out by the general practitioner, but if there is need for any operative work the gynecologist, the man who is skilled, should do it. Many cases suffer severely from irritable bladder, although I have found that this symptom exists only in patients having a lithemic or uric acid diathesis, and is rarely found in young girls, except in conjunction with pelvic disease. In from 75 to 80 per cent. of the cases in which this symptom exists it will disappear if you will correct the pelvic trouble and let the bladder alone. It is a constant symptom in every case of pus tubes and in cases of many other pelvic diseases. One of the most suspicious things a woman will tell you is: "Doctor, I have a great deal of trouble with my bladder." Find the cause of the trouble and remedy it; do it honestly, earnestly, manfully and fearlessly.

SKIN GRAFTING FOR THE RESTORATION OF THE EYELIDS.

REPORT OF CASES.*

OSCAR DODD, M.D.

Surgeon, Eye Department, Illinois Charitable Eye and Ear Infirmary; Assistant Clinical Professor of Ophthalmology (extramural) Rush Medical College.

CHICAGO.

Skin grafting for the restoration of the eyelids differs quite materially from that in other parts of the body. The prime objects in operating are cosmetic and restoration of function. To attain these the part must be freely movable and not differ in color and appearance markedly from the normal lid. We have also a field for operation which is movable and uneven, making the results more difficult to obtain. It is for these reasons that I think a discussion of the principles involved should be of benefit.

The statements I shall make and conclusions I have reached are from my personal experience with these cases. Along with the successes I shall give an account of my failures, for I think I have learned more from these than from the cases where the results were satisfactory. I have used most of the forms of grafts described, the sliding graft, the pedicle graft and transplantation of skin from another portion, either full thickness (the Wolfe graft) or the shaving graft (the Thiersch graft). The choice of which one to use must be determined by the individual case.

The primary causes for operating are usually cicatricial ectropion produced by burns, wounds or destructive skin lesions, as blastomycosis and lupus, or to fill in the defect after removal of tumors of the lid. Fortunately since the use of the *x*-ray the latter cases requiring operation are not so frequently encountered.

In the cicatricial cases we usually have the skin destroyed for a large area, and frequently so deep that the field for placing the graft is devoid of the normal blood vessels, and nutrition is a problem to consider. The condition is very different when the cicatrix is fairly superficial and can be entirely cut through when forming a floor for the graft.

In operating on the upper lid we have conditions very different from those found when operating on the lower. The graft on the upper lid must be as light as possible so as not to interfere with movement or press heavily on the eyeball. On the lower lid we have a tendency to draw away from the eye and we must have support for the lid margin.

I shall not consider the many methods of filling in small defects from the adjacent tissue when there is healthy skin near enough to make it possible. A great many methods may be used, varying with each particular case.

PEDICLE GRAFTS.

The pedicle graft has, in a measure, fallen into disfavor. That it has a place and one which can not be filled by either the Wolfe or the Thiersch grafts I am sure. The advantages of the pedicle graft are that when placed in a region devoid of the normal blood vessels it still has a source of nourishment. It also has the firmness and substance which is very necessary on the lower lids when the muscular tissue is atrophied, and especially when it is necessary to remove the whole thickness of the lid with a tumor. Shrinkage is at a minimum and should not be more than ¼ to 1/3 of the original size. It has also the advantage of being nearly like the skin it should replace and would only be conspicuous against the cicatricial tissue frequently surrounding it. Care, however, must be taken in men not to bring the hairy portion of the cheek around so as to transplant the whiskers on to the eyelids.

As to its disadvantages, the objection to the deformity which its removal may produce is of little importance, for the defect can be easily filled in by Thiersch grafts so that it is difficult to tell where it came from. The most serious difficulty I found was that they were too heavy for the upper lid, where I never attempt to use them now. In one of the first cases on which I operated a large pedicle graft was taken from the temple to form an upper lid, the greater part of which had to be removed with a tumor. It was so thick and rigid that the pressure produced corneal ulceration greatly complicating the condition.

WOLFE GRAFTS.

A great deal has been written both in praise and condemnation of the Wolfe graft. Before the shaving graft

---

*Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks.

came into use it was practically the only means of filling in a defect where the pedicle graft could not be used. Considering the experience of myself and others whose work I have had the opportunity to observe, I think the greatest fault is its uncertainty. I have obtained good results at the time, only to see them completely disappear a few weeks or months later, and that even when the conditions seemed most propitious for a permanent result. In the best results I have obtained the graft did not retain more than half the size soon after the operation. This does not refer to the size of the graft before cutting, which should be four or five times the size needed. Shrinkage has varied in my experience from this amount to practically complete disappearance in a few months. If we will consider the changes which occur in a graft we may understand the reason for this. The original vessels of the skin undergo hyaline degeneration and new capillaries spring from the neighboring parts. The superficial epithelium is cast off and the dermic layer is absorbed and replaced by new connective tissue, leaving the deep layers of the epidermis as the only part of the graft remaining.

In order to avoid shrinkage I have made my grafts as thin as possible and I find my results correspondingly improved. A very helpful suggestion was made to me by Dr. Arthur Prince, to stretch the graft and pin it inside out on a piece of sterilized board, and then with scissors and pincette remove all the tissue possible. Grafts treated in this way have little left but the epidermis, and their shrinkage is comparatively small.

Among the disadvantages in their use for cosmetic purposes is the difference in color and the growth of hairs. The color remains whiter than the surrounding skin in some cases for years, if not always. If a graft is taken from a hairy part of the body, as the arm or leg, there is apt to be a growth of hair that is very annoying. In their use on the lower eyelid they give support to quite an extent, and for that reason are to be preferred to the Thiersch graft in some cases. On the upper eyelid they are too heavy and should not be used except under special conditions.

THIERSCH GRAFTS.

The shaving or Thiersch graft which has most recently come into use is probably the easiest to handle. It seems to grow everywhere if a raw surface is prepared for its reception. While some would use it to the exclusion of all other forms of grafts, I think there are certain limitations which have to be taken into account.

In the preparation of the shaving graft I have found that the best plan was to have the skin perfectly dry, and with a dry razor remove the shaving, which should be placed on the surface previously prepared. Much better grafts can be cut in this way than when the salt solution is used, and very much less trouble is experienced in getting them into place. I have never had any trouble in making them grow if the surface was protected from the secretions of the eye, and could be kept quiet until adhesion took place.

As to shrinkage, we are told that none occurs after the graft has once healed. This depends entirely on the surface on which it is placed. When placed on a smooth surface which will not permanently contract, such as the fascia of a muscle, it will remain intact, as there is nothing in the graft itself to cause shrinkage. When placed on a surface in which there is some contractive tissue, as the lower eyelid after the removal of the outer muscles, the graft is very likely to entirely disappear. If placed on a granulating surface it will undergo the shrinkage of the underlying tissue. In several instances I used it to cover over a defect produced by destruction of part of a pedicle graft. The grafts would grow promptly, but later had completely disappeared from shrinkage of the underlying tissues.

On the upper lid they always served the purpose well. By cutting through the cicatricial tissue a smooth surface was obtained and the light graft was no obstacle to perfect movement. It is this which gives them preference over all other forms of grafts for the upper lids.

It has been demonstrated that the quicker the circulation of the graft is established after being put in position the less the subsequent shrinkage. For this reason the field on which the graft is placed should be smooth as possible and kept quiet so that no wrinkling will occur. To accomplish this I stitch the lids together when operating on the lower lid. I find the better plan to keep the upper lid in proper position is to put sutures through the edge of it and fasten to the cheek below with adhesive strips. This stretches the lid better, and gauze can be put along the edge to take up the secretion, which is frequently very profuse and troublesome, due to the previous exposure of the conjunctiva.

Fig. 1.—Case 1. Before any operation was performed.

I have not mentioned the operation where the conjunctiva is also destroyed, as occurs with some tumors. My results have not been satisfactory, and I should prepare a lining to the graft before swinging into place, as recommended by Everbusch. The skin should be dissected up some days before the operation and the under side covered with a Thiersch graft. As soon as it is well healed the flap may be swung into place and we have a covered surface to bring against the eyeball. In one of the cases which I shall report I used Thiersch grafts to cover the inner side of the lower lid made by a large pedicle graft. They healed in place well, but as the patient did not return for the final operation it was not a complete success.

I have said nothing as to the manner of placing or anchoring the grafts. Dr. Hotz has devised a method of anchoring in which the grafts are divided so as to fasten the edge of the one on the eyelid along the border of the cartilage on the upper lid and to the periosteum of the orbital margin for the lower lid. The remainder of the defect may be filled in by Thiersch grafts with

no fear of retraction, he says. My experience with this method is limited to one case, but the principle is a good one and I hope it will obviate some of the difficulties I have experienced.

REPORT OF CASES.

In order to illustrate better my conclusions I will report a few cases.

CASE 1.—This is of the severe type of cicatricial ectropion of both upper and lower lids. A man, aged 25 years, came under my care in the fall of 1900. He was injured in an explosion six years before, being thrown face down into a coke fire, where he lay for some time until rescued. His face was severely burned, especially over the nose and eyelids, and some distance on to the scalp. He had received no treatment except that immediately after the injury.

There was complete ectropion of both lower lids, and the skin was tightly adherent over the nose, the left side of which

Fig. 2.—Case 1. Immediately following the operations.

was partly destroyed and the left side of the mouth was drawn up by the cicatrix. The forehead was deeply cicatrized and the upper lids turned out at their edge, being completely everted when he tried to close the eyes. The eyeballs were fortunately normal in spite of the exposure, as the corneæ were only protected when the eyes turned up. The cheeks were not so deeply cicatrized, but enough to prevent any growth of the whiskers. In December, 1900, I operated to restore the right lower lid, taking a large skin flap from the cheek with a pedicle placed high enough so the contraction would not pull the lid down. This was sewed in place after dissecting up what remained of the lower lid and stitching to the upper. The field for placing the graft at the nasal side was entirely cicatricial tissue devoid of blood vessels except a few large ones, the oozing from which it was almost impossible to control. The graft was about 4 inches long and 2 inches at the widest point. It all healed well except a small piece at the tip where a hemorrhage had taken place underneath it. The defect in the cheek was closed up by loosening the skin and drawing together.

In January, 1901, I operated on the left lower lid in the same manner, but the tip and part of the lower border necrosed. Three weeks later I filled in the defects where the graft had necrosed, and also on the cheek with Thiersch grafts. These grew in place, but those on the eyelid completely disappeared later. One month later I operated on the upper eyelids, filling in the defects with Thiersch grafts. The secretion from the conjunctiva was so profuse that I could not keep the wounds free from infection and part of the grafts would not grow. I tried Thiersch grafts again and a pedicle graft on the left, but they all necrosed. I dressed the wound with oxychlorin for some time and then applied some Thiersch grafts, which healed in place. In March the patient had to go home, although there was some parts not healed. I have not seen him since, but he writes me that he has continued in good condition, and recently sent me the last pictures, taken two years after his discharge. The grafts seem to have remained in about the condition they were when he left.

CASE 2.—A man, aged 37 years, a carpenter by trade, entered the hospital in December, 1899, giving a history of having his face cut by a barber in June, 1895. It became inflamed and the wound discharged for six months. The redness and swelling gradually spread over the entire left side of the face and it was studded with clusters of pustules. He had been treated for years for lupus without result. Hearing that he had consulted Drs. Hyde and Montgomery, I took him to

Fig. 3.—Case 1. Two years after the preceding picture.

them for diagnosis. They pronounced it blastomycetic dermatitis, and under their direction he was entirely cured by the use of iodids in large doses and hot bichlorid of mercury lotion.

He entered the hospital again in December, 1900, with the disease cured, but with a dense smooth cicatrix extending from below the left jaw up to the nose and including the left temple and upper eyelid. The outer canthus was pulled out greatly and the lower lid drawn down and out and much stretched. As there was no tissue to make a graft on the face, I took a pedicle graft from the temple where the cicatrix was not very deep and swung it around to form the lower eyelid. As the scar tissue on the face was very deep it was difficult to stop the hemorrhage and the tip of the graft was forced out by the hemorrhage and necrosed. A few days later I covered the place on the temple where the graft was removed and the bare places on the lid with Thiersch grafts. In January, 1901, I operated on the upper lid and covered it with Thiersch grafts. The lower lid still having a tendency to ectropion, I made an incision near its border and filled in with Thiersch grafts. I closed up the outer part of the canthus by means of a Fuchs tarsorrhaphy.

In spite of perfect healing the Thiersch grafts entirely disappeared on the lower lid. On the upper lid, where I was able to get a smooth surface, they gave a perfect result as well as on the temporal wound, where it is difficult to tell their location.

Fig. 4.—Case 2. Showing the dense scar and ectropion of the eyelids of the left eye.

In January, 1902, he returned with epiphora and partial ectropion of the lower lid, and I made an incision along its border and filled the cavity with a Wolfe graft prepared very thin. This has kept the lid in very good shape and the graft

Fig. 5.—Case 2. About two years after the operations.

is about half the size it was when first placed a year ago. That it is impossible to tell the ultimate outcome in these cases is well shown by the fact that the contraction has apparently forced the large pedicle graft out toward the temple. This has allowed the lid to draw down some, but not enough, so I have thought best to operate again. The tension of the scar on the eyelids at the temporal end holding the outer

Fig. 6.—Case 3. Epithelioma of the lower lid.

canthus away from the eye is very troublesome, but I have not been able to devise any means to correct it.

CASE 3.—Man, aged 65 years, well nourished, came under my care in October, 1901, at the Eye and Ear Infirmary. About one year previous he had noticed a wart-like growth on

Fig. 7.—Case 3. About eighteen months after removal of tumor.

the left lower lid. This grew until at the time of entrance it involved the whole lower lid and extended a little beyond both outer and inner canthi. It was an epithelioma involving the whole thickness of the lid. I removed the growth and

formed a lid by a large pedicle graft from below on the cheek. I covered the inner surface with Thiersch grafts, as well as the defect on the cheek. It all healed in place well, but at the nasal end the scar at the line of union contracted so there is a defect. I wished to operate again, but he is so well satisfied with the present condition he will not consent.

Case 4.—Mr. T. had an epithelioma of the right lower lid involving the lid margin for about the outer half and extending well over toward the nose. In October, 1900, I removed the growth, leaving a large defect, which I was persuaded to fill in with a Wolfe graft from the arm. The graft was about 2x3 inches before dissecting up. It fitted in place well and the immediate result was good, but by January, 1901, it had shrunken to about one-half inch long and one-eighth inch wide, and ectropion had taken place. I then dissected it out thoroughly and covered the surface with Thiersch grafts. The results were perfect at the time, but later the contraction had caused a marked ectropion. In December, 1901, I filled in the defect by a sliding graft from below, but it was not sufficient to support it well and the edge of the lid turned out. In June, 1902, I put in a Wolfe graft prepared very thin, and that has given sufficient support, so the eye is well protected. The reason for failure in the first place was probably that the graft was too thick, leaving too much tissue to shrink. The last graft was prepared as thin as possible.

SUMMARY.

In conclusion I will summarize my results as follows:

For the upper lid Thiersch grafts should always be used, unless the whole thickness of the lid is destroyed.

In forming the lower lid, if there is adjacent skin available it should be used to form the lid and the resulting defect filled in with Thiersch grafts. When there is dense cicatricial tissue for the floor of the graft a pedicle graft is the only one which I have found satisfactory.

Should pedicle grafts not be available and the underlying tissue have proper vascularity, then either Wolfe or Thiersch grafts may be used, and my results have been best with a Wolfe graft prepared very thin.

DISCUSSION.

Dr. A. B. Hale, Chicago—In a severe burn from a gasoline explosion I followed the classical operation and made a flap; I want to warn against that method as a faulty operation. I did a Thiersch after that with a successful result. The vitality is too much impaired for a flap operation in these cases. A Thiersch gives better results.

Dr. Wm. H. Wilder, Chicago—As to the question whether we will employ a pedicle, or a Wolfe, or a Thiersch graft, I agree with Dr. Dodd in his conclusions. Where it is possible to get a pedicle graft from the forehead, or cheek, it should be used, for there is more assurance of its vitality being preserved than when the graft is taken from some more or less distant portion of the body. It is useless, of course, as Dr. Hale has said, to use a graft the vitality of which has been impaired or destroyed. The method used by Dr. Dodd of removing as much as possible of the fat from the subcutaneous tissue is a very good one. In my experience the Thiersch graft, where there is a contracting scar, will shrink. There is no one operation that will meet all cases of entropion. In some cases removal of a good part of the tarsus is a good procedure. One important step in the Hotz operation is the removal of the little bundle of muscle fibers just beneath the skin of the lower flap. This allows the lower flap to grow firmly to the anterior surface of the tarsus. Some operators prefer mucous membrane for marginal graft; I prefer something that will hold the lips of the wound apart, and accordingly use a skin graft taken from behind the ear.

Dr. C. W. Hawley, Chicago—The man who is in practice without a large clinic has few of these cases to operate on, so that my experience in skin grafting is limited. I had one case of a large fibrous tumor that occupied the region over the inner canthus. I employed a pedicle graft and the result was very good indeed. I have had more experience with operations on the eyeball with the Thiersch graft in relation to pterygia. I have tried both methods and, like Dr. Hale, want to say never use a mucous graft if it is possible to use a Thiersch. Your first operation may be a failure if you do not follow the advice given by Dr. Dodd, to cut them very thin. Within the last few months I saw an operation which was a failure simply for that reason; the graft was made very thick. At a second operation I suggested its being cut thin, and it was a success.

Dr. F. C. Todd, Minneapolis—Removal of the muscular tissue from under the skin as well as from the upper surface of the tarsal cartilage is essential toward securing firm union of the skin to its anchor, the cartilage, and is a feature of the operation on which Dr. Hotz lays great stress. Another point in securing a graft, which I learned from Dr. Wilder, is that of using an instrument he devised for grooving the cartilage, and which he showed several years ago at a meeting of this Section. He uses this instrument also for getting a graft from behind the ear or from the palm of the hand. There are two small blades that come together like a V and pick up a very neat graft, the width and length being governed by the pressure exerted in using the instrument. It is important to stop the hemorrhage with hot applications, for if we do not succeed in securing complete hemostasis the graft will not take, the blood preventing union. I now use in these cases adrenalin with excellent results. Of course, it is necessary that it should be aseptic. I do not think the use of adrenalin prevents uniting of the cut surfaces excepting when sepsis is introduced.

Dr. R. W. Miller, Los Angeles, Cal.—Controlling the hemorrhage is a very important point, and I have frequently used adrenalin; but it must be borne in mind that if it be freely used, unless a very firm after-dressing is applied, there is likely to occur secondary hemorrhage. Another good method of controlling the hemorrhage is to have an assistant compress the temperal artery.

Dr. Dodd—In regard to the point of Dr. Hale, my cases of Thiersch graft on the lower lid have been absolute failures. Dr. Hotz advocates the Thiersch graft as the only thing to use, and he says the reason I have failed with it is that I have not anchored my grafts properly to prevent contraction. I have only used his method in one case, and until I have had further experience it is impossible for me to judge of that point. I have never had any trouble with the Thiersch graft on the upper lid.

TRAUMATIC LESIONS OF THE OCULAR ADNEXA;

WITH REPORT OF A CASE OF CONTUSED WOUND OF THE EYEBROW, RESULTING IN COMPLETE MONOCULAR BLINDNESS UNACCOMPANIED BY OPHTHALMOSCOPIC CHANGES.*

ELLET O. SISSON, M.D.

Member Ninth International Ophthalmological Congress.

KEOKUK, IOWA.

Traumatic lesions of the ocular adnexa would include injuries of the eyebrow, eyelids, conjunctiva, orbital walls and soft parts of the orbit. This paper will deal more particularly with injuries of the eyebrows, orbital walls and soft parts of the orbit, as illustrated by the cases reported.

Wounds of the superciliary region are of frequent occurrence, and when superficial and limited to the soft parts, are not usually serious, but they may be followed by disastrous consequences, and even by fatal results should they affect or extend to the underlying bones.

If bone tissue is involved, osteitis, necrosis and fistulas may result. Suppuration of the orbital connective tissue is in all cases a serious complication of contusion of the superciliary region. Injury of the supraorbital

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks.

nerve may produce craniofacial neuralgia, muscular twitchings in the facial region, trophic changes in the eye, and finally give rise to visual disturbances that are characterized particularly by photophobia and accommodative asthenopia. This is particularly the case if the nerve or any of its branches is imprisoned in an adherent cicatrix.

As a rule, one or more of the walls of the orbit are involved in an injury to the orbital edge, but that the violence of the traumatism is undoubtedly neutralized, in part, by the prominence and the resistance of the edge of the cavity, is shown by Berlin's statistics, in which, out of 19 cases of simultaneous fractures of the edge of the orbit and of the vault, there were 16 recoveries, while 52 cases of fracture limited to the superior wall were followed by 41 deaths.

Again, direct fracture of the superior wall of the orbit is more liable to involve the optic canal. The optic nerve and its sheath are often violently torn and compressed, resulting in a retrobulbar neuritis with loss of vision, or a secondary form of compression from callosities or periostitis may take place followed by the same results.

Callan has recently reported nine cases of injury to the orbital walls, resulting in immediate unilateral blindness, in which it was believed that the line of fracture ran through the optic foramen.

Von Hölder has published the results of his examination of the bones in 124 cases of fracture of the skull. Among these there were 86 of fractures of the bone, and in 79 of these the fracture involved the roof of the orbit. In 63 cases there was a fissure or fracture running through the optic foramen, always through its upper wall, sometimes also through the inner wall. In 42 cases there was hemorrhage into the sheath of the nerve, and he never found blood in the optic sheath unless the bony canal was fractured. The hemorrhage was sometimes found in both optic sheaths.

As regards injuries to the soft parts of the orbit, it is a well-known fact that as a result of the shape and the free mobility of the eyeball, a wounding object may pass around its fibrous sheath and produce an injury of the surrounding soft parts of the orbit only. The importance of such a form of traumatism depends above all on the cleanliness of the penetrating body. If the offending instrument or foreign body has not been freed from septic material while passing through the skin, the conjunctiva, and the orbital septum, it may act as the cause of a cellulitis, endangering not only the vision, but also the life of the patient. Section of the ophthalmic vessels, rupture of the ocular muscles, injuries to the sensory and the motor nerves, and the presence of foreign bodies are among the most interesting lesions of those parts.

The ocular muscles are sometimes injured without any accompanying luxation of the eyeball; but these accidents are rather rare, not more than twelve or fifteen having been reported. The internal rectus is the one most frequently injured.

In these cases the loss of continuity of the muscular fibers has been both partial and complete. The prognosis, so far as the muscle is concerned, is generally favorable, for if a functional loss of power result it may be restored by operative interference.

Actual division of the motor nerves is rare. Berlin could find none such reported in literature. He himself reports two cases, which can not be explained in any other way than by division of the nerve fibers supplying the muscles.

In reporting the following case of a contused wound of the eyebrow, resulting in complete monocular blindness without ophthalmic changes, I do not report it as a rare injury, but because it serves to give a clinical picture of some of the main points in this paper.

CASE 1.—Mr. F. Van A., age 34, was caught by a belt of a rock crusher. His head was badly bruised and he sustained a severe cut over the right eyebrow in a transverse direction from the internal angular process of the frontal bone to the external angular process, and extending to the bone; injuring the periosteum at one point and passing directly across the point of exit of the supraorbital nerve.

The frontal sinus was not involved. The injury was followed by total loss of vision in the right eye. No ophthalmoscopic changes at this time. After the wound healed the patient suffered from craniofacial neuralgia as the result of the supraorbital nerve being imprisoned in the adherent cicatrix. Within a month's time the vision returned until the patient could see large objects about the room, but there was no further improvement. No ophthalmoscopic changes. In this case there doubtless was an indirect fracture of the optic canal, resulting in an injury of the optic nerve, which was followed by a retrobulbar neuritis.

The second case illustrates the result of an injury to the soft parts, and is rare, in that there was either rupture of an ocular muscle, detachment of its tendon from its insertion into the sclera, or an injury to a motor nerve, complicated with an injury to the terminal branches of the superior maxillary nerve with loss of sensation of the parts supplied by them.

CASE 2.—J. A. S. presented himself Jan. 19, 1901, at my office for examination, giving the following history: Dec. 31, 1900, he was struck in the right eye with the handle of a closed pocket knife held in the fist, the knife striking the lower margin of the orbit and the globe of the eye at its outer and lower quadrant. Swelling followed, and patient suffered considerable pain. There was loss of sensation over the region of the face supplied by the terminal branches of the inferior maxillary nerve; there was also loss of sensation in the gums of the upper jaw of the same side.

Patient placed himself under the care of a general practitioner, who gave him a simple eye wash. An examination of the eye revealed considerable lachrymation and photophobia, and some congestion of the eyeball at the point of injury.

It appeared as if the conjunctiva and Tenon's capsule had been torn by the blow. There was diplopia and the eye refused to turn out, indicating that there had either been an injury of the muscular tissue of the inferior oblique and external rectus, or a complete traumatic paralysis. There was also marked ptosis. V.=20/30. Fundus normal. At this time sensation had returned to the gums of the upper jaw, but there was still complete anesthesia of that region of the face supplied by the terminal branches of the inferior maxillary nerve. Unfortunately the case passed from observation and the permanent nature of the injuries was never ascertained.

The third and last case that I desire to report is a type of the more serious wounds that may occur in this region, and is interesting because of the extent of the injury, the complications, and the fact that there was no serious brain involvement.

CASE 3.—P. J., male, aged about 25 years, was shot in the head. Bullet entered ala of the nose on the right side, coursing upward and to the right, fracturing the right nasal bone. It then passed through the posterior half of the eyeball and lodged in the deep tissues of the orbit. There was great swelling and ecchymosis. An enucleation was made and the bullet extracted. Patient was in a semi-comatose condition at the time of the operation and remained so for twenty-four hours following. An interesting feature of this case was that it was complicated by infection. An abscess formed, the pus burrowing through the upper lid, leaving a good-

sized fistula. Healing took place soon after the formation of this opening, and the patient made a good recovery.

The main conclusions to be reached in a study of traumatic injuries of the ocular adnexa are: first, the necessity for a guarded prognosis in all cases and secondly, the value of asepsis and antisepsis in the treatment of all wounds located in this region.

DISCUSSION.

Dr. Casey A. Wood, Chicago—I have had a number of cases of incised wounds of the lids, involving their margins. We have an incised, or more frequently an incised and lacerated wound of the lids, penetrating the whole thickness of the lid, and generally we do not see these cases for some days or weeks after the injury. Some one has, perhaps, done his best to bring the wound margins together, and generally not very successfully, partly because of the irregularity of the edges and partly because of the sloughing due to infection or to the original injury. These have always been to me cases of great interest. After trimming the edges of the wound I have been in the habit of passing "anchor" sutures involving all the tissues of the lid, to keep the wound edges in close apposition (illustrating on board) on everting the lid. Then the conjunctiva down to the lid margin is sutured with a continuous thread, a separate suture being carried over the intramarginal space to bring the lid edge tissues close together. The skin is treated in like manner, after which I remove the deep sutures which only served a temporary purpose. This is the only way in which I have been able to accomplish the results we desire in these injuries, that appear so simple and yet require, if we desire good cosmetic results, rather careful treatment. As to gunshot wounds of the orbit, I have had two cases where the optic nerve was not injured, and yet optic atrophy was the result. Notwithstanding the "vibration" theory of some observers, I have not been able to satisfy myself as to the cause of this untoward result. Another matter worth considering is the "concussion" cataract that may follow almost any injury to the orbit, or to the head in the region of the eye. The old idea was that the concussion of the fibers of the lens brought about these secondary changes. I am inclined to think that it is really the profound though transient interference with ciliary circulation that brings about these cases of concussion cataract. Some years ago I published a number of these cases and have had several since. I am curious to know what the members of this Section think about the etiology.

Dr. Wm. C. Posey, Philadelphia—Three cases in which there was complete monocular blindness following an injury to the head, but in which vision was after a time fully restored, were reported by Nettleship and one by myself, before the College of Physicians of Philadelphia in 1899. In these cases the blindness is not immediate, but comes on some hours afterward. The ophthalmoscope shows evidence of compression of the fibers of the optic nerve, and from the deep-seated pain on motion of the eyeball, and a throbbing sensation which is occasioned by blowing the nose, involvement of the sphenoidal cells is indicated. These cases are of interest from a prognostic standpoint, for they show us that when blindness is not immediate after a head injury, vision may be regained, and every therapeutic effort should be made, therefore, to accomplish this result.

Dr. Harold Gifford, Omaha—Prior to this case of Dr. Posey's I was prepared to give my patients with blindness after a trauma of the orbital wall an unfavorable prognosis. I had never seen any of them recover, and had never seen the history of any recovery. Dr. Posey's case seemed to confirm so strongly the words of Panas: "The words 'never' and 'always' have no place in medicine." As to Dr. Wood's method, I have been afraid to leave knots on the under surface of the lid. In Königsberg, where similar operations are very common, the reports speak of inspecting the cornea from time to time "to see if the knots are causing ulceration of the cornea." In doing this kind of an operation I have been impressed with the importance of bringing the conjunctival edges into close apposition, and have passed the needle through the lid from its outer surface, then after completing a continuous suture of the conjunctiva have passed the needle clear through the lid again so as to leave both knots on the outer surface of the lid. The tension sutures which Dr. Wood says he takes out before bandaging the eye, I leave in. They are important in relieving the strain of the orbicularis on the other sutures.

Dr. John O. McReynolds, Dallas, Texas—My experience has been that in paralyses produced by injury to the nerves that supply the muscles of the eye the normal function of the muscles has returned. Further, if the blindness has been caused by hemorrhage, when that is absorbed the vision returns; but if there is fracture of the foramen with rupture of the nerve, rapid, white atrophy ensues with no return of vision.

Dr. Oscar Dodd, Chicago—I remember well two gunshot wounds of the orbit. The son of a physician had a small shot pass through the upper lid and produce complete blindness, probably by striking the optic nerve. There was no change in the nerve, however, when I examined him two weeks after the injury. The other case had a bullet from a revolver held against the temple pass through the orbit, injuring the optic nerve. In this case there was atrophy of the nerve. As to those wounds of the upper lid, mentioned by Dr. Wood, I have often found the retraction very difficult to prevent. In some cases it produces considerable deformity. I always sew the conjunctiva and skin separate, and, when possible, I trim the edges so they will overlap and the lines of union will not be opposite each other. This helps to prevent the retraction.

Dr. Allen Greenwood, Boston—Dr. McReynold's statement is the common experience, I think, as the optic nerve passes through so small a foramen that any fracture there will crush it. In the other nerves the injury is not from crushing, but rather from pressure of exudates and hemorrhages. I had a case recently of such an injury, where a small boy received a blow on the infraorbital ridge with apparently no injury to the brain. In a week, when the bandage was removed from the eye there was blindness with complete paralysis of the external rectus, probably due to fracture near the base. The paralysis of the external rectus disappeared in a week's time, while the injury to the optic nerve resulted in complete atrophy. The optic nerve was distinctly atrophic a week after the injury.

Dr. Edw. Jackson, Denver—I think probably the important point in reference to the prognosis in these injuries involving blindness is the time in which the blindness supervenes. If it is a direct injury to the nerve the blindness will be immediate, and there will probably be no recovery whatever. But in a large number of them the blindness is not immediately discovered; the patient is stunned; or in other cases there is a good deal of effusion and the eyelids are closed for some days. In a case where there was a clear history of seeing at all, certain light perception, after the injury, I think the prognosis would be at least a chance of some recovery of sight. But if there has been no vision in the eye after such injury, the probabilities would be strongly against any recovery of sight. All cases of direct injury to the optic nerve that caused serious impairment of vision that I have known of have shown no evidences of sight after the injury at all. I recall one case of gunshot injury where the patient was not much shocked and the first thing he noticed was that the eye was blind. The optic nerve had been cut by the shot. I think the point to determine the prognosis would be whether or not the blindness was immediate.

Dr. Albert E. Bulson, Jr., Fort Wayne, Ind.—We should not lose sight of the fact that many of these cases are caused by hemorrhage or effusion, and in such cases the prognosis is more favorable. If we put our patients at absolute rest and begin eliminative treatment we will sometimes secure results that at first may seem impossible. I had one such experience in a case where there resulted absorption of the effusion around the optic nerve which had produced total blindness. The patient secured 20/50 vision following treatment of a condition that seemed to offer little hope of favorable results. Our prognosis should be guarded.

DR. LEARTUS CONNOR, Detroit—It strikes me that about this topic there are as many sides as to a sphere. I recall two cases of gunshot wound of the orbit that were never followed by any ill result. I recall a recent case of a woman in middle life, who, when a child of 6, fell against a door and hit her left eye at the outer brow. There was no scar to indicate the lesion, but from that time the eye turned outward and she had double and imperfect vision. When I saw her she had a choroidal atrophy with some optic atrophy. I presume at that time there was probably hemorrhage in the fundus of the eye. I never feel able to say at the time of injury just what result may be expected.

DR. WILLIAM ZENTMAYER, Philadelphia—I wish to call attention to the frequency with which we find central choroiditis, or perhaps in some cases holes at the macula, in these cases. In some instances it may be the primary trouble and the optic change is secondary.

DR. SAMUEL L. LEDBETTER, Birmingham, Ala.—About two years ago I had a patient who had been struck in the eye by the breech pin of a gun and the ball destroyed. It gave no trouble other than the loss of sight. The patient came to me saying that lately he found there was something in the outer angle of the eye that gave him trouble. I found a piece of a glass bottle ⅝ of an inch across, and supposed I had gotten that which caused all the trouble. He said that about three months before he had thrown at a dog and struck a bottle and that a fragment flew back and struck him in the eye. Ten days later he came back with a suppurating sinus. I cut down into the tissues and found a metallic substance below the surface, which was removed with difficulty. It was the breech pin of the gun, measuring 1½ inches in length and ⅞ inch in diameter and weighed 1½ ounces. It had been there three years.

DR. JOHN E. WEEKS, New York—I would like to mention a few cases that show the extensive injury to the orbit that can be sustained without affecting the eyeball. The first patient attempted to commit suicide, shooting himself in the temple. The ball passed through both orbits without in any way interfering with vision. Another case somewhat remarkable was that of a young man who was fencing. The point of the foil struck him just below the margin of the lid, in the left eye; the only wound was a tearing of the skin, which was raised for perhaps the distance of 1 cm. Very shortly after this occurred there was paralysis of the external rectus. This lasted for six weeks, disappearing gradually. Another case was one in which a young man in falling caught on a meat hook which entered the orbit, caught up the internal rectus and tore it across without injuring the eyeball, but lacerating the lid somewhat. There was, of course, a marked divergence, but by catching up the tissue of Tenon's capsule together with the torn muscle and suturing it to the eyeball the diplopia was corrected.

THE PRODUCTION AND NATURE OF STREPTOCOLYSIN.*

GUSTAV F. RUEDIGER, M.D.
CHICAGO.
(From the Memorial Institute for Infectious Diseases.)

In 1897 Bordet[1] drew attention to the fact that there generally is more or less hemolysis in the blood of a rabbit which has died of streptococcus infection. This hemolysis is not constantly observed, but was present, for instance, in 37 of 40 rabbits dying of streptococcus infection, in which it was looked for in this laboratory during the last eight months. This phenomenon seems to be unique in the field of bacteriology, although there are several other organisms, such as the *B. tetanus*,[2] *B. pyocyaneus*,[3] *Staphylococcus pyogenes*,[4] *B. typhosus*,[5] *M. tetragonus*,[6] *B. megatherium*,[7] and others,[8] the filtered cultures of which are capable of hemolysing red corpuscles of various animals. These organisms, however, do not produce hemolysis in the body of an animal which has been injected with the young cultures, as is the case with the streptococcus. Todd[7] has found, however, that filtrates from an old culture of *B. megatherium* produce hemoglobinuria in a guinea-pig, when injected subcutaneously. If larger quantities are injected hemoglobinuria, hematuria and finally death of the animal are produced. Kraus and Ludwig[9] found marked anemia in rabbits after the subcutaneous injection of old cultures of *Staphylococcus pyogenes aureus*, or their filtrates.

Bordet's observation soon led to the attempt to produce this hemolysin in a test tube, but the earlier experiments were uniformly unsuccessful. It was found that filtered cultures, in all ordinary media, possessed no hemolytic properties, regardless of how strongly that same streptococcus produced hemolysis when injected into a rabbit. Recently, however, Besredka[10] succeeded in getting filtrates that hemolysed not only rabbit corpuscles, but also those of many other animals, by growing a virulent streptococcus in heated rabbit serum and passing through a Chamberland filter. Besredka made a close study of this streptocolysin, but none of his experiments throw much light on the nature of this substance. In consideration of this fact it was suggested to me by Professor Hektoen to repeat the experiments, with the view of verifying Besredka's findings, and to carry the work further in an attempt to throw some light on the nature of streptocolysin.

The streptococcus used in these experiments was obtained from a retroperitoneal abscess in a guinea-pig, which had been injected intraperitoneally with a fungus. It forms rather short chains, renders ascites-bouillon uniformly turbid and acidifies milk in 24 hours, but does not coagulate it. When it was isolated 5 c.c. of a 48-hour culture killed a full-grown rabbit in 4 days. The virulence was increased, by passage through 30 rabbits, until 0.0003 c.c. of a 24-hour culture in ascites-bouillon kills a rabbit in less than 20 hours.

Streptocolysin was prepared in practically the same manner as described by Besredka. The best results were obtained with filtrates prepared as follows: Mix 1 part of human serum with 2 parts of rabbit serum, heat the mixture to 56 C. for 30 minutes, inoculate this with a young virulent culture of streptococci, incubate for 20 to 22 hours, dilute with an equal volume of physiologic salt solution,[11] and pass through a porcelain filter.

Besredka recommends that the inoculation be made directly from the heart's blood of a rabbit which has just died of streptococcus infection and in which hemolysis has taken place. This was not found necessary. The dilution with salt solution is recommended to facilitate filtration of the serum. Great care must be observed in the selection of a filter. While the serum must pass through perfectly clear and free from streptococci, too fine a filter must not be used, as it removes from the

11. 0.75 per cent. salt solution was used in these experiments.

serum its hemolytic property. If the serum loses most of its color while passing through the filter it is likely to be worthless.

Filtrates obtained in this manner were proven to be sterile by inoculating a tube of ascites-bouillon with 1 c.c. of filtrate and incubating for 48 hours. No growths were obtained. They hemolyse both washed and unwashed corpuscles of man, rabbit, dog, goat, sheep, beef, hog, guinea-pig, chicken and horse—in fact, all that have been tried. The corpuscles of man and rabbit are least resistant. One drop of a thick suspension of these corpuscles, washed, is completely hemolysed by 1 c.c. of streptocolysin in 1½ hours, if kept in the incubator. Those of chicken, beef and horse are somewhat more resistant than the others, but their dissolution is considerably hastened by washing them five times in physiologic salt solution before they are subjected to the influence of streptocolysin.

The fact that these corpuscles are hemolysed more rapidly after being washed at once gave rise to the suspicion that there is something in the sera of these animals—antihemolysin—which protects the corpuscles against streptocolysin. That this supposition is correct is proven by the following experiment: Take four small test-tubes, (a), (b), (c) and (d), and introduce 1 c.c. of streptocolysin into each. To (a) add 1 c.c. of normal chicken serum and in one-half hour add one drop of normal chicken blood. To (b) add 1 c.c. of physiologic salt solution and one drop of a suspension of washed chicken corpuscles, in physiologic salt solution. To (c) add 1 c.c. of chicken serum which has been heated to 55 C. for one-half hour, and in one-half hour add 1 drop of a suspension of washed rabbit corpuscles. To (d) add 1 c.c. of salt solution and 1 drop of a suspension of washed rabbit corpuscles. Transfer all tubes to the incubator and examine in five hours. There is complete hemolysis in (d) and (b), but no hemolysis in (a) and (c). No hemolysis is observed in (a) and (c) in eight hours, but there sometimes is a trace in 24 hours. The sera of beef and horse also protect the corpuscles against streptocolysin, but not so completely as does chicken serum.

Many other substances, as solutions of various salts and colloidal solutions of gold and platinum, were tested for antihemolytic properties, but with very little success. A 1 per cent. solution of formaldehyd in physiologic salt solution retards hemolysis for 5 to 6 hours if it is mixed with streptocolysin in equal proportions before the corpuscles are added. Treating the corpuscles with such a solution for 1 hour, washing and then adding them to a tube of streptocolysin does not interfere with their hemolysis.

The filtered cultures in heated rabbit serum of two non-virulent streptococci were tested for hemolytic properties, but these filtrates produced only a trace of hemolysis in 24 hours.

Other sera than rabbit serum may be used as culture media in the preparation of streptocolysin, but the substances produced in these sera are not so active as those produced in rabbit serum. In studying the streptocolysins produced in different sera Besredka came to the conclusion that they are not alike. He found, for instance, that streptocolysin produced in human serum hemolyses corpuscles of man, rabbit, guinea-pig, goat and sheep, but not those of chicken and goose. That produced in goat serum hemolyses corpuscles of man, rabbit and guinea-pig, but not those of goat, sheep, chicken and goose. He concluded from these findings that streptocolysin, and hence also the products of other bacteria, may be different if produced in different media.

These experiments were carefully repeated, but Besredka's findings could not be verified. It was found that streptocolysin produced in goat serum hemolyses corpuscles of goat, sheep and chicken just as does that produced in human serum or in rabbit serum. The latter, however, hemolyses in a much shorter time than do either of the other two.

Many bacterial toxins are destroyed by heating to 56 C. for one-half hour, but that is not the case with streptocolysin. It may be heated to 60 C. for one-half hour without being inactivated. If heated to 65 C. for one-half hour its value is greatly impaired, but it is completely inactivated only by heating to 70 C. for 2 hours. If once inactivated, it can not be reactivated by the addition of complement. It is inactivated by leaving in the incubator at 37 C. for 5 days. If kept at room temperature it is still hemolytic at the end of two weeks, and if preserved in an ice-chest it remains active for more than a month. Freezing for a short time does not destroy it.

It is non-dialysable. Five c.c. of the filtrate were kept in a dialyser for three days, but when taken out it hemolysed as rapidly as it did before. Digestion with pepsin for 14 hours at 39 C. destroys it.

Turning to the consideration of the nature of streptocolysin, we may compare its behavior with that of other hemolysins, the nature of which has already been determined. Is it an alkali, which was recently shown by Jordan[12] to be the nature of pyocyanolysin? This question is answered readily in the negative because streptocolysin is faintly acid to phenolphthalein (0.3 per cent.), and it is destroyed by heating to 70 C. for two hours.

Is it one of those complex substances depending on the combined action of an intermediary body and complement, which was shown[13] to be the constitution of many natural hemolysins as well as of those found in the sera of animals which have been repeatedly injected with the red cells of an animal of a different species? This question also may be answered in the negative from the following considerations:

(a) Complement, as it is ordinarily known, is destroyed by a temperature of 56 C. in one-half hour. Streptocolysin may be heated to 65 C. for one-half hour without being destroyed, and when it is inactivated by a still higher temperature it can not be reactivated by the addition of complement. Hence we may conclude that we are not dealing here with complement as it is ordinarily found.

(b) In the case of natural hemolysins and those produced by immunization, the intermediary body alone may be bound to the corpuscles and thus removed from the serum. This is done by keeping a mixture of corpuscles and serum at a temperature near 0 C. for 30 minutes or more, and then centrifugalizing and drawing off the clear serum. If now the corpuscles are washed in a cold salt solution and incubated no hemolysis takes place. The addition of complement to these corpuscles brings about hemolysis. If, on the other hand, fresh corpuscles are added to immune serum which has been treated in the cold with an excess of corpuscles no hemolysis is observed.

The behavior of streptocolysin is quite different from this, as is shown by the following experiments:

12. Trans. Chicago Path. Society, 1902, v, 175.

13. Ehrlich and Morgenroth: Berlin. klin. Wochenschr., 1899, xxxvi, 6.

1. Mix one-half c.c. of a thick suspension of washed rabbit corpuscles with 2 c.c. of streptocolysin and keep the mixture below 3 C. for 5 hours. No hemolysis is observed. Centrifugalize in a cold place, draw off the clear serum and wash the corpuscles five times in salt solution. Now suspend them in 2 c.c. of salt solution and incubate. No hemolysis takes place, even after the addition of complement. Add fresh corpuscles to streptocolysin which has been treated in the cold with an excess of corpuscles, and hemolysis is produced by incubating for 2 hours.

2. Make a similar mixture of streptocolysin and corpuscles as was used in experiment 1 and keep it at a temperature of 6 C. for 3 hours. No hemolysis is observed. Centrifugalize in a cold place, draw off the clear serum and wash the corpuscles five times in cold salt solution. No hemolysis takes place during the washing if the temperature is kept below 6 C. Suspend the corpuscles in salt solution and incubate for 2 hours. Marked hemolysis will now be observed.

Streptocolysin, therefore, is not similar to the immune hemolysins; it is not a substance depending on the combined action of an intermediary body and complement.

I have carried the study farther in order to determine whether or not streptocolysin is similar to diphtheria toxin, tetanolysin and staphylolysin. These substances, as was shown by Ehrlich,[14] Madsen,[15] and Neisser and Wechsberg,[16] respectively, are composed of a complex molecule in which are linked together a haptophore and a toxophore group. By means of the haptophore group, which may be active at a low temperature, the toxin attaches itself to the cell, and not till then can the toxophore group exert its destructive effect over the cell, and then only at a temperature approaching that of body heat.

This, as we have just seen, is precisely the behavior of streptocolysin. At a temperature of 6 C. it may be bound to the red corpuscles so firmly that it can not be removed from them by repeated washings, but hemolysis takes place only after the temperature is raised considerably above this point—best at 37 C.

The existence of a haptophore and a toxophore group is still more strongly indicated by the following experiment: Take 2 c.c. of streptocolysin, add one-half c.c. of a thick suspension of washed rabbit corpuscles and keep the mixture at the temperature of 6 C. for 3 hours. No hemolysis takes place. Centrifugalize in a cold place, draw off the clear fluid and wash the corpuscles five times in cold physiologic salt solution. Now divide them into 3 equal portions, (a), (b) and (c). To (a) add 2c.c. of salt solution; to (b) add 1 c.c. of heated chicken serum and 1 c.c. of salt solution and to (c) add 2 c.c. of salt solution to which has been added 1 drop of a 5 per cent. solution of zinc chlorid. Incubate the tubes and observe in 5 to 6 hours. There is marked hemolysis in (a) and (b), but no trace of hemolysis in (c).

We have already seen that heated chicken serum is antihemolytic, if it is added to an equal volume of streptocolysin, and corpuscles added later. But this serum is no longer capable of preventing hemolysis if added to corpuscles which have been treated with streptocolysin at 6 C. for 3 hours and then thoroughly washed, although hemolysis may still be prevented at this stage by the addition of a trace of zinc chlorid or zinc sulphate. It seems now that this peculiar behavior of streptocolysin is best explained by the assumption that we are dealing here with a haptophore and a toxophore group which are linked together in one molecule. The chicken serum, therefore, either destroys the haptophore group, or something in it combines with this group and saturates it, so that the streptocolysin can not become bound to the corpuscles. The toxophore group remains unaffected. According to the theory, this should prevent hemolysis, and the experiments have shown this to be the case. Zinc chlorid, on the other hand, is capable of arresting hemolysis after the streptocolysin has been bound to the corpuscles, and this effect seems to be due to its action on the toxophore group. It must be added that corpuscles which have been treated for 1 hour with a weak solution of zinc chlorid and subsequently washed, are readily hemolysed if mixed with streptocolysin and incubated.

Several attempts have been made to immunize rabbits against streptocolysin, in the hope of producing antistreptocolysin in their sera, but, so far, these experiments have been unsuccessful. All of the rabbits died after receiving from 2 to 5 injections of 0.5 c.c. each. This work is being continued, and will be reported more fully at a later date.

The toxicity of these filtrates was further determined by injecting seven rabbits with varying quantities. Six of these died, while one receiving 2 c.c. intravenously is alive four weeks after the injection. Cultures made from the heart blood, liver and spleen of these animals were sterile. This work also is being continued, and will be reported in a subsequent paper.

CONCLUSIONS.

Virulent streptococci, when grown in heated rabbit serum (and other sera), produce a hemolysin which destroys the red corpuscles of many animals.

This hemolysin is an organic substance which is destroyed by heating to 70 C. for 2 hours.

It gradually deteriorates if kept at room temperature, but may be preserved in the ice chest for a much longer time.

In the incubator it deteriorates very rapidly.

It is destroyed by peptic digestion.

It is non-dialysable.

It is composed of a haptophore and a toxophore group, which are firmly bound together. The haptophore group may be neutralized with chicken serum and the toxophore group is destroyed by zinc chlorid.

The sera of some animals contain antistreptocolysin.

A weak solution of formaldehyd has antihemolytic properties.

The filtered cultures of a virulent streptococcus, in heated serum, are toxic for rabbits.

I desire to take this opportunity to thank Professor Hektoen for suggestions and encouragement.

THE PURIFICATION OF WATER SUPPLIES BY SLOW SAND FILTRATION.

(*Continued from page 911.*)

III.

WATER FILTRATION IN THE UNITED STATES (CONTINUED).

B. THE ALBANY FILTRATION PLANT.

The Albany plant is the largest of its kind now in operation in this country and also deserves consideration from the fact that the best and most modern experience

Fig. 3.—General view of Hudson River, pumping station and sedimentation basin, Albany water works.

was utilized in its construction. The sanitary results flowing from the operation of this filter are especially noteworthy since before filtration the water had proved highly injurious to the public health.

Fig. 4.—Construction of filter basin. Laying water-tight bottom.

The city of Albany, N. Y., with a population of about 100,000, is situated on the Hudson river about eight miles below the mouth of the Mohawk. The total urban population in 1900 on the watershed above Albany was about 376,000 and, including the rural population, amounted to 80 per square mile, or somewhat less than the number on the Merrimac watershed above Lawrence (104). Before the establishment of the filtration plant the raw water of the Hudson river constituted the main supply of the city. The opportunities for pollution at Albany were even more grossly conspicuous than at Lawrence. Only four miles above the water intake, the city of Troy, with a population of 60,651, poured its untreated sewage directly into the Hudson river and, in addition to this source of flagrant contamination, the city of Albany was guilty of the monstrous sanitary blunder of fouling its own nest. Although the majority of the Albany sewers entered the river below the intake, the tidal currents, which at low water make themselves felt as far up the river as Albany, would at times sweep the city's own sewage up stream and into the water intake. The freshness of the sewage, both

Fig. 5.—Interior of filter bed, showing roof, underdrain and layer of sand and gravel.

from the Albany sewers and from the close-lying city of Troy, rendered the pollution at Albany much more dangerous than was indicated by the simple proportion of "organic matter" in the river water. In view of these

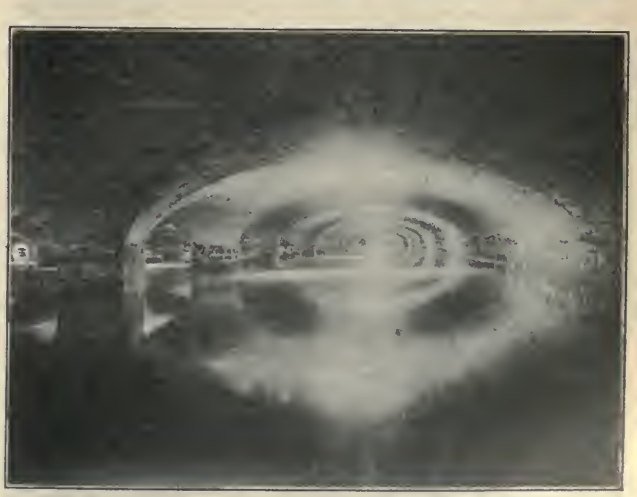

Fig. 6.—Interior of filter basin during operation.

circumstances it can not excite amazement that typhoid fever prevailed at Albany to an alarming extent, and that the city enjoyed the distinction of maintaining one of the highest death rates from typhoid fever in the United States.

The Albany filter was built in 1898-9 and was completed Sept. 6, 1899. A portion of the city supply—about two-sevenths—is still derived by gravity from small lakes and reservoirs, so that it is impossible to draw entirely precise conclusions in regard to the rela-

tive effect of filtered and unfiltered water. The apparent influence of the filter in reducing typhoid fever in Albany will be considered presently.

The Albany filter was constructed in an economical and highly efficient fashion. The plant consists of a pumping station, where the water is pumped from the "back channel" of the Hudson river into a sedimentation basin with a capacity of about 14,000,000 gallons. From the sedimentation basin the water passes to the filter beds, eight in number and provided with covers of

Fig. 7.—General view of completed sedimentation basin, central comb covered filter (with ventilators showing) and laboratory.

vaulted masonry. The cost of the covers formed as much as 30 per cent. of the total cost of the filter, but the unfortunate experience of Lawrence, which we have already recounted, and of other places have supplied abundant evidence that in a cold climate the expenditure for covers is warranted by all considerations of economic and efficient management. It may be said in passing that the total cost of the Albany filters was much less

Fig. 8.—Central comb and gate-house, sand washing in the foreground.

—$45,600 per acre, including covers—than the average figures derived from various European construction accounts. It must be admitted, however, that at Albany the site and other conditions were especially favorable and that at the time when the filter was built the market for the materials of construction was at a much lower level than at present.

One particular in which the Albany plant departs advantageously from the older European type of filter is in the specially careful arrangement of the layers of gravel on which the sand rests. The whole gravel layer is considerably thinner than in the older works and is composed of three strata of graded sizes. The use of gravel of different sizes prevents the upper layers from being washed into the lower ones, and is regarded as being a highly commendable feature of the Albany plant. The pure water reservoir, which is rather unusually small, and the ingenious and novel method of controlling the rate of filtration involve other features of engineering interest which need not be here considered.[6]

The Hudson river water, as regards turbidity, occupies a position midway between the very clear waters of New England and the muddy waters of the Middle West. When high turbidity appears in the water it persists longer than in the Merrimac river. In respect to pollution, the quality of the Hudson river at Albany is far below the average of surface waters that are safe for drinking in a raw state. The bacterial content is high (Table 3), and the unmistakable indications afforded by the typhoid fever death rate show that much of the organic matter in the water is sewage of recent origin.

The amount of water filtered between scrapings, which affords some clew to the nature of the water filtered,

Fig. 9.—Sand washing.

averaged in 1901 about 68,000,000 gallons per acre, or about 47,000,000 per individual filter bed. The average number of days between scrapings was about 25. The bacterial efficiency of the plant is shown in the following table:

TABLE 3.

Year.	Bacterial Count—Average per cc. In Raw Water.	In Filtered Water.
1900	33,600	265
1901	47,800	470
1902 (nine months)	25,500	134

Attention may be called to the large number of bacteria in the raw water of the Hudson at Albany as compared with the Merrimac water. The percentage removal appears from the averages to be about the same as at Lawrence, although the actual number of colonies appearing in the effluent are somewhat greater at Albany. Averages, however, are notably misleading, as shown by the following table giving the results for a single year:

6. We are indebted to Mr. Allen Hazen, the designer of the Albany filter, for his courtesy in allowing us to reproduce some photographic views of the Albany filter in various stages of construction and completion. Certain of the general features of interest common to all modern filters are shown in these photographs, as well as the special features of the Albany plant.

TABLE 4.

1901.	Raw Water. Average.	Pure Water. Average.
January	71,400	300
February	105,100	2,117
March	123,700	1,601
April	107,600	276
May	26,500	92
June	15,800	106
July	7,700	39
August	8,300	42
September	7,600	46
October	4,350	49
November	21,635	290
December	74,100	680

It will be observed that during the greater part of the year the number of bacteria in the effluent is very much below the average for the whole year. The high numbers recorded during the winter months appear to be due to the fact that the filter is forced beyond its legitimate capacity to meet the excessive consumption or waste of water in cold weather. The operation of the filter beds in winter at a rate far above their normal capacity causes a falling off in the bacterial efficiency.

The effect of the operation of the filter on the death record in Albany has been marked. The following table shows the average number of deaths from typhoid fever during the ten years preceding the opening of the filter, and the corresponding number of deaths since the filter was put in operation:

TABLE 5.

DEATHS FROM TYPHOID FEVER IN ALBANY BEFORE AND AFTER THE OPENING OF THE FILTER.

Months.	Average No. of Deaths for 10 Years Prior to Opening Filter.	1900.	1901.	1902.
January	11	3	2	2
February	11	1	3	3
March	12	3	1	2
April	9	5	1	1
May	4	4	1	2
June	4	1	3	1
July	4	3	0	1
August	7	6	3	4
September	6	4	4	2
October	4	5	0	0
November	5	4	0	0
December	7	0	1	0
Total	84	39	19	18

A comparison of the cost of operation of the Albany and Lawrence plants, together with that of two smaller sand filters, is given in the following table:

TABLE 6.

COMPARISON OF COST PER MILLION GALLONS OF OPERATION OF FILTERS AT LAWRENCE, ALBANY, POUGHKEEPSIE AND MT. VERNON.

(To be continued.)

Clinical Report.

A CASE OF ACCIDENTAL ELECTROCUTION

FROM ORDINARY ONE HUNDRED VOLT ALTERNATING LIGHTING CURRENT.

C. VAN ZWALUWENBURG, M.D.

RIVERSIDE, CAL.

To those who study the effects on the system of electric currents the following record of death from an alternating lighting current of only 100 volts may be of interest:

S., a carpenter, well built, stocky, about 5 feet 9 inches, weighing about 165 pounds, was at work repairing a building in Riverside, Cal., about 2 o'clock p. m., Aug. 11, 1903. The building, a two-story block with flat tin roof, had been scorched by fire April 22, 1903. S., with two companions, was making repairs in the attic immediately under the roof in a space only about 4 feet high, between ceiling and roof joist. He was perspiring very freely—the temperature there must have been about 100 F., with no air stirring. As he crouched on his knees and reached over to drive a nail into a studding he threw his head back just enough to bring the occiput in contact with a wire running to a drop light in the ceiling. The insulation had been burned away and in his condition of extreme perspiration, his clothing soaked, all the conditions for transmission of current were at their best. He was probably on a gas pipe, which made an excellent contact for grounding the current. At the instant of contact he made an outcry as though he had received some slight injury, then straightened backward in a general convulsive movement until his body lay in extreme opisthotonos, having carried the wire down from its fastenings, but continuing the contact at the same point.

The companion nearest him rushed to his assistance, received a considerable shock from handling the wire, but succeeded in removing the victim from contact in from 15 to 30 seconds. It was between 5 and 10 minutes before he could be brought down a ladder to the floor, during which time he was said by his companions to gasp several times. By this time Dr. Parker had arrived and at once began artificial respiration, which was continued systematically with tugging on the tongue for one hour, but no further signs of life were elicited at any time. I arrived about 15 minutes after the accident occurred. Rubbing and applications of hot and cold water and hypodermics of strychnin, digitalin and nitroglycerin were also used.

The only evidence of injury was a slight burn about 3/16 of an inch wide and about 2½ inches long, beginning at a point about 1 inch back of the tip of left mastoid and extending backward and upward into the hairy scalp to a point about midway between the posterior inferior angle of the left parietal bone and the median line of the occiput. The burn was very superficial, scarcely through the cuticle.

Our city electrician was promptly on hand and made a careful search for cross wires which might have carried in a heavier current, but none could be found, and he declared after testing the current that the only charge Mr. S. received was the ordinary lighting current as distributed to individual or chandelier lights. This current is the ordinary lighting current, 100 volts, varying slightly and occasionally perhaps reaching 110, run from a 50 cycle 6,000 alternation system.

The explanation of the fatal effect of so light a current must be:

1. The point of contact at the base of the brain.
2. The probable grounding through the gas pipe.
3. The absence of resistance in the skin on account of its thorough saturation with saline water from extreme perspiration.
4. The length of time contact continued on account of the body falling on the wire.

I find very little literature on this subject of the strength of current necessary to cause death, and that is my reason for reporting this case.

This report has been submitted to Dr. A. S. Parker, Dr. C. S. Dickson, the coroner who took the testimony in the case, and Mr. F. A. Worthley, our city electrician in charge of the lighting plant.

Needs Investigation.—The *Alienist and Neurologist*, calling attention to the king snake, whose assault no other snake can withstand and which is immune to the poison of the cobra and of the rattlesnake, asks: "Is the blood of the king snake antidotal to other snake poison? Here is a suggestion for the laboratory of experimental toxicology. Toxicological therapeutists may find in the serum of the king snake an antidote for the sting of the cobra, and the rattler and other venomous reptiles."

SATURDAY, OCTOBER 17, 1903.

A UNITED PROFESSION IN NEW YORK STATE.

The grounds for discord that have so long existed between the members of the profession of New York state have been removed, and there is no longer any reason whatever why there should be two opposing organizations, each having the same objects. That this fact is realized is shown by the recent action—as reported in our last week's issue—of the New York State Medical Association, and harmony in the near future seems to be well assured.

The action of the council and fellows of the New York State Medical Association in appointing a committee with full powers to meet with a similarly qualified body from the Medical Society of the State of New York has been met by the latter body, and consequently we may hope for immediate measures to consummate the union of the two organizations. There may be some difficulties, or rather minor details, for adjudication by the committees, questions of what should be of comparatively slight importance, but nothing that ought to in any way prevent or seriously delay union. The time has now arrived for individuals to lay aside personal feelings, jealousies and selfishness, if anything of the kind still remains, for the sake of the good of all. There is now no real grievance; no principle whatever involved, and we are sure that no one desires schism for schism's sake alone.

Whatever there may have been in the past to excite bad feeling should be ignored; a disunited medical profession is an evil that all should strive to overcome. We have no expectation, however, that there will be even a minimal percentage of members of either of the state bodies that will take any exception to the proposed reunion. We have full faith in the members of the committees on both sides, as broad-minded men having the best interests of the medical profession at heart, and believe that they will let nothing stand in their way in bringing about the desired result.

With a united profession acting as a unit in the state the possibilities for advancing medical interest and forwarding the necessary measures, legislative and otherwise, for the protection of the public, as well as for the welfare of our profession, will be doubled. We know from the activity of the bodies separately what they can do when united. It is union, not competition—with its accompanying bad feeling and jealousies that have existed in the past—that is desired. We sincerely hope that there will be no serious difficulty or delay in bringing about that harmony in the Empire state which has for years been so anxiously hoped and watched for by the profession of the whole country, and the lack of which has been a misfortune to all concerned. Union must come; to delay it is worse than folly.

DRUG HABITS.

In the October number of the *Journal of Pharmacy* is an interesting article by Messrs. Eberle and Gordon of the committee appointed by the American Pharmaceutical Association to report on the acquirement of drug habits. They give the results of a statistical inquiry which has been instituted, but which is necessarily somewhat incomplete. There is more of interest in their general remarks on the subject, since they are based largely on personal knowledge.

The report shows that the opium habit is markedly increasing; the majority of the class known as habitual criminals are opium habitués. The reporters state that the drug habit has alarmingly increased in the Army and Navy and that opium smoking has been acquired by some of our soldiers in the East. In the Navy this method of taking the drug is less common, but the habit of opium eating has been acquired to some extent in the intercourse with natives of foreign countries. It is encouraging to note that not a single case of the drug habit coming from the prescribing of opium by medical officers could be recalled; opium and the allied drugs are very guardedly and carefully used by the Army and Navy medical officers. An unfortunate percentage of the members of the hospital corps have drifted into the habit from the constant opportunity in handling the drug.

That part of the report which refers to the use of cocain and the cocain habit shows a worse state of affairs. The drug is sold undisguisedly in many drug stores and the druggist buys it in 100-ounce lots, sometimes as often as once a month. One drug store in Philadelphia which does little prescription and no hospital business, is particularly mentioned, though not by name, and is referred to as only one instance out of many.

The effects of the cocain habit are not so generally known as are those of morphin, but there is nothing yet discovered that has such a baneful effect on the user. One of the reporters says that he has seen the drug literally "turn a bright high-principled man into a sneak thief and liar absolutely without regard for morality or principle. One redeeming feature is that the habitual use of cocain seems to lessen sexual ability and desire, so there is less danger of its transmission by heredity." Nine-tenths of the cocain habitués seem to have acquired the habit by the use of patent medicines or prescriptions, and it is rapidly supplanting the use of morphin among men and women of the "under world." The importation

of the cocain salts has increased from $176,948 worth in 1901 to $254,704 in 1902 and $199,826 for the first nine months of 1903. Averaging $3 per ounce as the value of cocain, this gives us an increased importation of 25,000 ounces in 1902 and over 22,000 ounces for the nine months of 1903, a fact which speaks volumes in itself. The use of smoking opium is also increased in a similar manner, but the same was not so true of the morphin salt in 1902, but it has greatly increased in importation in the present year.

The need of legislation in regard to this matter should be emphasized. Something must be done; we have cocain laws in a few states and city ordinances in certain localities, but thus far practically little has been done to stop the baneful habits in this way. The amount of cocain, for example, that can be legitimately used for medicinal purposes certainly bears very little proportion to the total imported amount now used, and an increase such as is represented above is a very bad omen for the future of our population. National legislation is certainly required; the United States government permits the importation of smoking opium for no better reason than the vender has for selling it, and it is a national disgrace that such is the case. Over 100,000 pounds of opium for smoking purposes were imported last year, and the importation is increasing each year. If matters go on as at present the time will come when there will be as important a business interest at work in the matter of drug selling and encouraging the habits as already exists in the case of alcohol.

Any new drug which can affect the nervous system seems to obtain its habitués. The heroin habit has made its appearance, headache remedy habits are reported, diarrhea remedies are reported habitually used by a large number who sooner or later become morphin or laudanum users. Unfortunately, a large number of cases are reported as directly due to careless prescribing by physicians. Physicians must be guarded and careful in the use of such remedies and must discourage in every possible way the use of proprietary remedies containing them; we must work with all our might for national and local legislation restricting the use of the habit-producing drugs and for the suppression of drug habits.

STOKES-ADAMS DISEASE.

In spite of the fact that this remarkable clinical condition was described by Adams in the Dublin Hospital Reports as early as 1827 and much more fully by Stokes in his article entitled, "Observations on Some Cases of Permanently Slow Pulse," in the *Dublin Quarterly Journal of Medical Science* in 1846, too little attention has been paid to it by the profession at large—so little noticed, indeed, that many good practitioners of to-day scarcely know what is meant by the term.

The disease, or rather symptom complex—for the anatomic lesions are not constant nor the etiology uniform—is, however, by no means an infrequent one, and it is characterized by a group of symptoms which permit it to be easily recognized. The patient suffers from attacks of syncope, often described as "apoplectic attacks," associated with a very slow pulse rate—28 or 30 beats to the minute. The slow pulse may be due either to true or false bradycardia; occasionally there may be complete cardiac arrest for as long as half a minute, after which the heart again begins to beat. Accompanying the more severe attacks there is usually marked involvement of the vasomotor system, revealed by pallor, vomiting and sweating, and sometimes by numbness and tingling—symptoms resembling closely those which occur in angina pectoris.

The nervous features of the disease are those which are most troublesome to the patient, and concerning which he consults a physician. Complaint is made of attacks of dizziness and staggering without known cause, or there may be sudden "fainting spells" with complete loss of consciousness. In some instances the symptoms resemble closely an attack of apoplexy; there is deep coma with loud, stertorous breathing and facial congestion, but the pseudo-apoplectic nature of the attack is shown by the absence of consecutive paralysis. Occasionally actual epileptiform seizures occur.

Three groups of cases are distinguished: 1, A postfebrile group; 2, a neurotic group, and 3, an arteriosclerotic group. By far the majority of the cases met with belong to this third group. The pathology of the affection is as yet quite unknown. The cases are largely confined to the period of advanced life, though occasionally a young individual is attacked. The prospect of recovery, once the severer nervous symptoms have appeared, is unfavorable. The attacks may go on occurring, however, for years. Death is, as a rule, sudden in one of the seizures. The most that can be done in the way of treatment is to attempt to prevent the progress of an underlying arteriosclerosis, when that exists. In the syncopal attacks nitrite of amyl may be used.

Stokes-Adams disease has in recent years begun to attract the attention of a number of the ablest clinicians in this country and abroad, and it is to be hoped that we shall ere long have new light thrown on its etiology and pathogenesis. Among the more valuable articles dealing with the subject are those by Huchard[1] in France, Hoffmann in Germany and Osler[2] and Edes[3] in this country.

GRANTS FOR SCIENTIFIC WORK.

One of the first results of the small grants given by the American Medical Association to promote scientific research is embodied in the article by Gustav F. Ruediger in the present issue of THE JOURNAL. It appears that pathogenic streptococci have the power, under certain conditions, of producing a substance that causes laking and destruction of red corpuscles (hemo-

1. In his "Traité des maladies du coeur."
2. Lancet, Lond., Aug. 22, 1903.
3. Phil. Med. Jour., 1901.

lysis). In the case of rabbits, this laking occurs during life in the course of streptococcus infections. In view of the frequency and of the gravity of streptococcus infections in man, this being probably our most frequent secondary infection and certainly the principal element of danger to life in the course of smallpox and scarlet fever, any definite advance in our knowledge of the pathogenic action of streptococci is most desirable. Now the production by streptococci of a definite poison to red corpuscles explains very satisfactorily the grave anemia that commonly develops in streptococcus infections. Ruediger shows that streptocolysin is a single substance, thus differing from the majority of hemolysins which depend for their action on the combination of two different elements, the intermediary body and the complement. Streptocolysin is in nature like the diphtheria toxin and tetanus toxin.

This fact having been established, further work may develop other similarities between these bacterial toxins, e. g., the property to cause the development of specific antitoxins. Streptococcus infections have proven to be a serious stumbling block in the way of successful treatment by antiserums. Success perhaps awaits more exact knowledge of the modes in which streptococci cause their pathogenic effects. At present the exact mechanisms of streptococcus infections are not clearly understood, and on this account they invite to continued, persistent, detailed investigation, and it is to be hoped that work of this kind may be stimulated by the Association grants.

Grants for research are probably the most fruitful method of investment for the surplus funds of the Association. The returns will consist, first, in the immediate results of the particular investigations made possible by the grants and, secondly, in the encouragement thus given to the development of investigators. "It is in the multitude of scientific workers that there is hope. The man of genius is a rare bird, and we must have a numerous class from which to produce him." Perchance the grants given by the Association may prove, sooner or later, the welcome means of discovering some man of genius and starting him on a career of epoch-making investigation. This phase of the setting aside of funds for research should be kept prominently in view by the committee having the matter in charge. When a grantee demonstrates his ability to produce definite results from actual, original investigation, let him receive all possible encouragement, to the end that he may be able continuously and persistently to push his work forward.

THE EVOLUTION OF THE COLOR SENSE.

A number of years ago Gladstone theorized—from the poverty of words indicating color in ancient Greek literature—that the color sense, as we now possess it, is a comparatively late acquisition. His view was strongly combated at the time and has not since received any general acceptance. It is, of course, impossible to say just what color vision the Homeric Greeks possessed, and we have perhaps no modern races exactly corresponding to them in social and intellectual development.

We have, however, some facts that may be considered as favoring Gladstone's theory; we know, for example, that certain refinements of sensation are cultivatable, and there is some testimony that in some of the lower races the special sensibility in one way or another is not exactly the same as with the more civilized races. Accurate psychometric studies of savages have hitherto been largely lacking, but attention has been directed to the need, and we may obtain data that will decidedly modify the prevalent views on the subject. An indication that such may be the case is apparently afforded by the recently published psychometric studies of the natives of Murray Island, in Torres Straits, by Dr. W. H. R. Rivers, noticed in *Nature,* September 3. His observations are especially significant, for he found the color sense decidedly deficient in these savages, and the objection that only the descriptive terms were wanting was not found valid—sensation was most defective just where the nomenclature was most lacking. The natives generally recognized red and yellow, and green for special reasons, and had names for these colors, but their ideas of blue were very indefinite, and it was confused with blue green or dirty brown. Only the most decided blue tint seemed to make an impression. A curious fact noticed was the complete absence of red-green blindness, and another was the fact that the peripheral retinal perception of blue was most complete, and its visual field the most extensive, which is contrary to the rule. Other senses tested by Dr. River's colleagues showed aberrations which were decided, though perhaps less striking than those for color. Acuteness of hearing was lower than in the white, as were also the pain and weight senses. Tactile sense was more acute, and the visual reaction time slower, while the auditory reaction time was the same as in the European. There was no name for bitter, but the sensation evidently existed.

The savage races of the earth are disappearing rapidly, and the scientific value of such investigations on their psychometric aberrations can not well be over-estimated. It is only by such research that we can even approximately settle such questions as that raised by Gladstone, and the bearings of these points on the early history of our race can readily be appreciated. If followed up and associated with equally thorough anthropometric studies, brain measurements, etc., they may throw light on many questions of development and physiology. They should be more generally made, and should be correlated with every phase and grade of social development from the lowest savages up to the highest uncivilized races, and it may be that practical as well as scientifically valuable results will be obtained. The better knowledge of the evolution of the color sense may lead to methods of its education and betterment and the prophylaxis of color-blindness.

SYPHILIS IN ANTHROPOIDS.

Medical men everywhere will watch with interest the progress of the experiments now being conducted by Metchnikoff at the Pasteur Institute in Paris on the susceptibility of the anthropoid apes to syphilis.[1] It is stated that thus far the French scientist has succeeded in producing a typical initial lesion of syphilis in one animal shipped to him from Liverpool by inoculating it with virus from a secondary syphilitic lesion in man. The celebrated syphilographer, Fournier, has examined the animal carefully and gives it as his opinion that the lesion produced is undoubtedly specific. If these statements are verified, it must be granted that a most important step forward has been made in our knowledge of this most ancient and prevalent disease; for the experience of the last few years has taught us that one of the first *desiderata* for the successful study of an infectious disease is to be able to reproduce it in animals, so that it can be subjected to experimental study and the conditions of experimentation be controlled at will. Hitherto syphilis has been unknown in animals other than man. Attempts have been made repeatedly to transmit the disease to lower animals, but without success. If any animal is susceptible, it is most likely to be found among those highest vertebrates which are so fearfully human in form and whose tissues are presumably chemically most similar to the tissues of man. The French savant has proceeded on this theory and apparently his efforts have been crowned with success. The cost of experimentation on gorillas and allied forms will, of course, be enormous; a single animal sold to the Physiologic Laboratory at Liverpool not long ago brought no less than $1,800 in cash to the importer. But in the investigation of a disease like syphilis, the money should be easily forthcoming as soon as those who have it to give can be assured that its expenditure offers a fair hope that something greater than anything we know yet may be done in preventing the spread, or in promoting the cure, of this frightful disease.

Medical News.

ILLINOIS.

Smallpox at Westfield.—It is reported that smallpox is prevalent in Westfield to such an extent that the public schools have been closed.

Must Report Births.—Section 2 of the new law provides that "every physician, midwife, parent, or householder shall be paid for each report of birth made in the manner directed by the State Board of Health the sum of 25 cents." The law is mandatory and for its violation a penalty of a fine varying from $10 to $100 is provided.

Illinois Mortality for July.—During July, 1903, 4,903 deaths occurred in the State of Illinois, according to the mortality report for that month just published by the State Board of Health. This report is based on the certificates of deaths received in the office of the board from physicians outside of the larger cities of the state in which burial permits are required, from the registration officials of these cities, and from the coroners of the several counties. These certificates were forwarded to the State Board of Health under the provisions of the birth and death law of 1903 which repealed the Act of 1901 requiring a burial permit. The report has been delayed by the failure of several county clerks to furnish physicians and coroners with blank forms for reports of deaths. A few weeks ago the State Board of Health had printed and distributed among the physicans of the state over six thousand books of blank forms, and as a result several hundred belated reports have been received by the board during the past week. The published death-rate is slightly less than that of July, 1902, when 5,107 deaths were reported to the county clerks, but it is the opinion of the State Board of Health that many additional reports for July will be received during the present month. The reports for July, 1902, should be absolutely correct, as it was then obligatory on physicians to furnish a certificate of death before the burial of the body. The ten principal causes of death and the number due to each are given as follows: Gastro-enteritis in infants, 673; tuberculosis, 537 (tuberculosis of the lungs, 447; other forms, 90); accidents, 483; pneumonia, 218; typhoid fever, 88; suicide, 70; diphtheria, 57; whooping cough, 50; measles, 39, and scarlet fever, 32. The reports for July, 1902, showed 681 deaths from gastro-enteritis in infants and 542 deaths from all forms of tuberculosis.

1. The Journal A. M. A., October 3, page 861 and previously.

Chicago.

Sherrington Banqueted.—Prof. L. Sherrington, Liverpool, was the guest of honor at a banquet given by the faculty of Rush Medical College, October 5. President Harper introduced Professor Sherrington to the faculty and delivered the address of welcome.

Dispensary for Maternity.—Contracts have been let for a dispensary to be built at the southwest corner of Maxwell Street and Newberry Avenue in connection with the Chicago Lying-in Hospital. It will be three stories high, 25 by 60 feet, and will cost $15,000.

Mortality.—For the week ended October 3, the total deaths were 467, an annual death-rate of 13.26 per 1,000, consumption leading with 55 and acute intestinal diseases coming next with 51. For the week ended October 10 the deaths were 427, an annual death-rate of 11.81 per 1,000, consumption again leading with 49, and being followed by acute intestinal diseases with 46.

Books Stolen from Marine Hospital.—A considerable number of valuable medical books, including Deaver's Surgical Anatomy in 3 volumes and Dennis' Surgery in 4 volumes, have been stolen from the library of the U. S. Marine-Hospital. Each volume has the government stamp on the title page. Should any of these books be offered for sale the surgeon-in-charge, Dr. Charles E. Banks, desires to be informed, that he may recover the books and prosecute the thief.

MARYLAND.

Frederick County Medical Society.—This society has purchased a three-story house in Frederick and will convert it into a hospital and training school for nurses. The board of directors has elected the following officers: President, Dr. William H. Wagner, Woodsboro; vice-president, Dr. D. Edwin Stone, Sr., Mt. Pleasant; secretary, Dr. Henry P. Fahrney, Frederick, and treasurer, Dr. William C. Johnson, Frederick.

Baltimore.

Deaths and Births.—The deaths for the week ended October 10 were 183, which is an annual rate of 16.88 per 1,000. There were 206 births, and 5 deaths from typhoid fever.

Personal.—Dr. Henry Barton Jacobs has returned from Europe.——Dr. Glanville Y. Rusk has been appointed to a position in the New York Pathologic Institute.——Dr. Norman McLeod Harris of the Johns Hopkins Hospital has received an appointment in the bacteriologic department of the University of Chicago.——Dr. E. H. Hume has gone to England.——Dr. Harry O. Wilmot of the City Hospital left, October 10, for Folsom, W. Va., where he will practice.——Dr. Mary N. Browne has been appointed demonstrator of obstetrics in the Woman's Medical College.——Dr. N. G. Keirle, Jr., is pursuing study in a special line of surgery at St. Mark's Hospital, London.——Dr. Albert Shelley has returned from England.

MASSACHUSETTS.

Thousands for Hospitals.—The hospital of the city of Melrose will receive $1,000 from the estate of the late Royal F. Barry. ——The Clinton Hospital Association receives $10,000 by the will of Richard W. Foster.

Smallpox Stamped Out.—Smallpox may be regarded as stamped out of Massachusetts. Very few cases exist within the borders of the state, these few are nearly all imported and no new cases at all are reported for the week ended October 10.

Associated Boards of Health.—The quarterly meeting of the Massachusetts Association of Boards of Health will be held in Clinton October 22. A paper by Dr. Robert W. Hastings, resident physician of the Boston Floating Hospital, on

"Etiology and Treatment of Summer Diarrheas of Infants," will be followed by a description of the great waterworks of the metropolitan water supply. The dam and reservoir, which are located at Clinton, will then be inspected by the association.

Deaths and Diseases.—During the five weeks ended October 10 there were reported 970 deaths in Boston, a decrease from last year of 40 and an average annual death rate of 16.76 per 1,000. Among the prominent causes of death were: Pneumonia, 61; whooping cough, 4; heart disease, 80; bronchitis, 16; and marasmus, 31. One hundred and seventy-four cases of diphtheria, with 19 deaths, were reported; 92 of scarlet fever, with 1 death; 137 of typhoid fever, with 20 deaths; 75 of measles, and 184 of tuberculosis, with 115 deaths.

MISSOURI.

Personal.—Dr. Edward J. Davis, St. Louis, superintendent of Provident Hospital, has been appointed resident physician of the Indian school at Zuni, N. M.

Sanitarium Burned.—At a fire, October 1, which destroyed the private sanitarium of Dr. Benjamin B. Ralph, Kansas City, one patient was killed and five were badly injured. The loss was $4,000.

Pleaded Guilty.—Dr. Walter McKinley, Grant City, charged with having violated the postal laws by sending forbidden matter through the mails, pleaded guilty, concluding "that it was wiser to plead guilty and pay a fine than to go to the trouble and expense of fighting the case."

Forgiven This Time.—Nolle prosequies were entered in the cases of four physicians charged, October 1, with not having registered at the St. Louis health department. This action was taken at the request of the board of health. The physicians were Drs. Oscar P. Hedger, 2628 Osage Street; Harmon Mehrs, 3300 Commonwealth Avenue; Charles McGinnis, 3204 South Jefferson Avenue, and Harry Upshaw, 3762 Morgan Ford Road.

Crusade Against Quacks.—A warrant has been issued against Charles De Meyer, 919 Olive Street, St. Louis, for practicing medicine without a certificate from the State Board of Health. This is the first state case made by the health department of St. Louis in its efforts to purge the city of irresponsible and irregular practitioners.——Mrs. Sylvia Pfeiffer, St. Louis, was fined $25 and costs for failing to register with the board of health, as required by law.

University Year Opens.—The Marion-Sims-Beaumont College of Medicine, the medical department of the St. Louis University, opened for the year, October 1, with an increase in the number of students. Among the additions to the faculty are the following: Dr. B. Meade Bolton, professor of pathology and bacteriology; Dr. Albert C. Eycleshymer, director of the department of anatomy, histology and embryology; Dr. Augustus V. L. Brokaw, professor of operative and clinical surgery; Gustavus D. Hinrichs, professor of chemistry and director of chemical laboratories; Peter Potter, associate professor of anatomy; Herbert P. Johnson, associate professor of bacteriology; James M. Wilson, instructor in embryology and comparative anatomy, and S. Walter Ransom, instructor in research work.

NEBRASKA.

Hospital Closes.—The board of directors of the Fremont hospital decided that the institution could not be made to pay, and it was closed permanently September 30.

Going to the Philippines.—Drs. C. L. and Leta M. Pickett, Tecumseh, sailed for Manila, September 19. They are to be stationed as medical missionaries at Laoag, Luzon, 250 miles north of Manila.

Colleges Open.—The year's work of the Omaha Medical College, the medical department of the University of Nebraska, was inaugurated September 22 at a meeting at which the principal address was delivered by Dr. Henry B. Ward, dean. ——The fall term of Creighton Medical College, Omaha, opened September 22.

Hold Charges in Abeyance.—The State Board of Health, in the case of Dr. Charles W. Downs of Omaha, charged with distributing pamphlets tending to corrupt public morals, has decided to hold the charges in abeyance, on the plea of the accused that he was ignorant of the law, and on his promise not again to offend.

Irregular Fined and Banished.—Salomon T. Metty, who has claimed to be able to cure all diseases, but had not obtained a license to practice from the state medical board, was fined $100 and costs, $26.50, at Nebraska City, September 30. His friends paid the fine, and he was released on agreeing to leave that section of country. At the trial it was brought out that the defendant was a horse-trainer by profession.

NEW YORK.

Sexagenarian Takes Examination.—Among the candidates who appeared at Syracuse, September 18, was a graduate of Denver University, 64 years of age.

College Opening.—The seventy-third session of Albany Medical College was commenced, September 22, with addresses by Dr. Willis G. Macdonald and President Andrew V. V. Raymond of Union University. A portrait of Dr. James H. Armsby, for many years professor of anatomy and surgery, was unveiled. ——The medical department of the University of Buffalo was formally opened, September 28, with an address by Dr. Carlton C. Frederick.

Personal.—Dr. George Blumer, Albany, has resigned as adjunct professor of pathology and bacteriology and has been succeeded by Dr. Richard M. Pearce of Philadelphia, who will have as his assistants Drs. E. M. Stanton, New York, and Charles K. Winne, Mount Wilson, Md.——Dr. Montgomery A. Crockett of Buffalo has returned from a three months' visit to Germany and Switzerland.——Dr. Charlotte B. MacArthur, Rochester, has been appointed assistant physician of the Willard State Hospital, vice Dr. Ernestine J. Hills, deceased.

New York City.

Physician Shot.—Dr. Rodney C. Combes, Corona, Borough of Queens, was shot, October 7, in the right leg by the husband of a patient who recently escaped from his sanitarium.

Cornerstone Laid.—The new building for St. Mary's Hospital, Jamaica, is under construction. The cornerstone was laid September 20; the hospital is to accommodate about 300 patients.

Hundreds Barred.—As a result of medical inspectors' reports the board of health has excluded from the schools 175 children suffering from trachoma, 139 from conjunctivitis, 59 from parasitic diseases, and 3 from skin diseases and one from tonsillitis.

Memorial Hospital Sold.—The Memorial Hospital for Women and Children, Brooklyn, was sold at auction under foreclosure proceedings, September 22, for $96,500. It is understood that the purchase was made on behalf of the Jewish Hospital Society.

Jury Disagreed.—In the suit for malpractice brought by an alcoholic patient against Drs. G. Lenox Curtis and John H. Storer, in which he alleged that he had been seriously injured while undergoing electric-light treatment and had been damaged to the extent of $10,000, the jury disagreed.

Deplore Robert Newman's Death.—At a special meeting of the faculty of the New York School of Physical Therapeutics, September 14, resolutions were adopted bearing testimony to the honesty, courage, and kindliness of the late Dr. Robert Newman, and extending its sympathies to the bereaved family.

Cornell Begins.—On September 30 the work of Cornell University Medical College began for the year with an increased enrolment in the junior and senior years, but with no increase in freshmen, due probably to the higher entrance requirements, which are practically the same as those for admission to the academic department of the university.

Columbia Medical School Opens.—The opening exercises of the College of Physicians and Surgeons were held September 24. Dr. Nicholas Murray Butler, president of Columbia University, presided, and in a brief address of welcome announced the foundation of a special medical library for the medical college. Dr. Walter B. James also spoke on "The Old and the New Medicine."

Official Changes.—Dr. Edward T. T. Marsh has been appointed president of the Board of Police Surgeons, vice Dr. Stephen G. Cook, removed. Dr. Henry P. DeForest has been appointed secretary of the board.——Dr. Frederick A. Jewett, chief of the bureau of contagious diseases, Brooklyn, has been made diagnostician to the department. His successor is Dr. Benedict of Manhattan.

New Contagious Disease Hospitals.—The health department has prepared plans for the building of a hospital to cost $75,000 in the Borough of Queens to accommodate 20 patients; a new pavilion with a capacity of about 200, near the Kingston Avenue Hospital; a scarlet fever building to accommodate 200 patients at the foot of East Sixteenth Street, and a small reception hospital at Richmond.

OHIO.

Fined For Assault.—Dr. Ralph E. Brake, Findley, was fined $150 and $28 costs, September 21, for assaulting Walter Herrick.

Western Reserve Opens.—The medical department of Western Reserve University, Cleveland, opened October 2 without formal ceremony.

License Revoked.—On account of habitual drunkenness, the State Board of Medical Registration and Examination, on October 6, revoked the license of a practitioner.

Hanna Endows Chair.—The medical department of Western Reserve University, Cleveland, has received $100,000 from H. Melville Hanna, to endow a chair of research in anatomy.

Rheumatism Specialist Fined.—"Dr." D. J. Zilkon, Cleveland, a so-called specialist on rheumatic diseases, pleaded guilty to practicing without a license and was fined $25 and costs, at Lorain, September 25.

Municipal Sanatorium Opened.—The new tuberculosis sanatorium at Cleveland was opened October 4, and 32 patients were transferred to it from the City Hospital. There is room for about 60 more patients. The fresh air and diet treatment will be carried on at the institution.

Personal.—Dr. Robert C. Heflebower, Cincinnati, has returned after a visit of five months to Denmark.——Drs. Arthur G. Helmick and William H. Pritchard, Columbus, have been appointed assistant physicians at the Ohio Hospital for Epileptics, Gallipolis.——Dr. William J. Wall, Jr., Cleveland, jail physician, has been deposed.——Dr. William L. Buechner, who has been a member of the Youngstown Board of Health for thirty-three years, has resigned.——Dr. John E. Stemler, Cincinnati, has been appointed receiving physician of the City Hospital, vice Dr. Oliver P. Coe, resigned.——Dr. Ira B. Hunter, Sandusky, assistant surgeon at the Ohio Soldiers' and Sailors' Home, has resigned.——Dr. Madison E. Baldwin, Arcadia, has returned from Europe and has opened an office in Toledo.——Dr. William V. Anderson, Toledo, has been appointed workhouse physician, vice Dr. William S. Walker, resigned.

TENNESSEE.

Personal.—Dr. James M. King, Nashville, has been appointed a member of the board of education.——Dr. C. T. Love, McLemoresville, was thrown from his horse, September 21, and received severe internal injuries. He is now reported to be improving.

Open for Year's Work.—The medical departments of Vanderbilt University, the University of Tennessee and the University of Nashville, opened for the season on October 1.——Tennessee Medical College, Knoxville, will open November 2, a month later than usual, and will close June 1.

Faculty Changes.—At the University of Tennessee, Nashville, Drs. Robert Caldwell and W. Herman Myers were appointed demonstrators of anatomy, Hon. Nathan Cohn, professor of medical jurisprudence, and Dr. William E. Hibbett, professor of diseases of children. At Tennessee Medical College, Knoxville, Dr. Samuel M. Miller, professor of obstetrics and gynecology, has resigned, and has been succeeded by Dr. A. G. Kyle.

Rogers Lectureship at Memphis.—The directors of the Memphis Hospital Medical College have established a lectureship in memory of the late William E. Rogers, M.D., founder of that institution. Once during each session a lecture will be given by a specialist in some branch of medical science. The first lecture will be given about the middle of November by Dr. Charles H. Hughes, St. Louis.

TEXAS.

Yellow Fever.—Up to October 10, 172 cases of yellow fever had been reported at Laredo, with 7 deaths.

Epileptic Colony Open.—The State Epileptic Asylum at Abilene was ready to receive patients October 1. The building will accommodate about 200.

Personal.—Drs. Thomas B. Bass, Terrell, and J. H. Eastern, Waco, have been elected assistant physicians at the State Epileptic Colony, Abilene.——Drs. George H. Moody, San Antonio, and Frank R. Ross, Austin, have returned after a five-months' stay in Vienna.

College Openings.—The thirteenth annual session of the medical department of the University of Texas, Galveston, began October 1. The opening address was given by Dr. James E. Thompson, professor of surgery.——The medical department of Fort Worth University opened October 1.——Dallas Medical College opened for the year on September 28.

Faculty Changes.—The Board of Regents of the University of Texas, Galveston, have elected Dr. Alfred E. Thayer professor of pathology to succeed Dr. Allen J. Smith, who resigned to accept the chair of pathology in the University of Pennsylvania. Dr. Thayer was formerly instructor in pathology and bacteriology in the Cornell Medical School, New York, and has held the fellowship in pathology in Johns Hopkins University. ——Dr. William S. Carter, professor of physiology, succeeds Dr. Smith as dean of the medical faculty.——At Fort Worth University, Dr. Robert B. Grammar has been made instructor on diseases of children; Dr. M. E. Gilmore, assistant in surgery and demonstrator of anatomy; Dr. William Rounds, assistant in pathology, and Dr. Charles P. Brewer, lecturer on materia medica and pharmacy.

GENERAL.

Boards of Health to Confer.—The eighteenth annual meeting of the Conference of State and Provincial Boards of Health of North America is to occur in Baltimore October 23 and 24. The program includes the subjects of yellow fever, venereal disease, infantile diarrhea, transportation of the dead, vital statistics, reform in county health officials' methods of work, and tuberculosis.

The Union of the Profession in New York.—A special meeting of the Medical Society of the State of New York was held Tuesday evening, October 13, in the Academy of Medicine, to consider the proposition for the union of two organizations, made by the New York State Medical Association.[1] The large hall was well filled, and amid enthusiastic applause and congratulations the society unanimously adopted the following resolution, which was introduced by Dr. B. St. John Roosa:

WHEREAS, The New York State Medical Association, at a special meeting duly assembled, has, by unanimous vote, appointed a committee with full power to meet a similar committee of the Medical Society of the State of New York to arrange for the unification of the two organizations under the corporate name of the Medical Society of the State of New York, therefore, be it

Resolved, That the committee of conference of the Medical Society of the State of New York, already appointed, be given power to vote, and other powers commensurate with, those recently granted the committee created by the New York State Medical Association for the purpose of unifying the two state medical bodies.

Rates to American Public Health Association.—Supplemental to the information in THE JOURNAL, Oct. 3, 1903, page 871, Dr. H. L. E. Johnson, chairman of the subcommittee of this association on railroad rates, states that one and one-third fare to Washington and return for the meeting, October 26 to 30, has been granted by the Canadian, New England, Trunk Line, Central, Southeastern, Western and Southwestern Passenger associations. The Western Passenger Association has granted this rate on the condition that 100 passengers from their territory attend the meeting, therefore the committee advises that if there is doubt that 100 will attend from the western territory, delegates should purchase tickets locally in this territory to some eastern gateway, viz.: Chicago, Peoria or St. Louis, and there purchase one-way tickets with certificates to Washington, D. C. The Transcontinental Passenger Association will sell nine-month return tickets at two cents per mile from Pacific and intermediate points to eastern gateways, viz.: Missouri River points, Chicago, St. Louis, etc., where delegates can purchase direct to Washington, D. C., on the certificate plan. Local ticket agents will explain and advise how to purchase most advantageously and arrangements should be made with them for through tickets and certificates several days before starting.

Army Death Rate Larger.—The mortality from cholera in the Army caused a slight increase in the total death rate during the fiscal year ended June 30, 1903. The Filipinos and Malays in the Army had a higher death rate, but a very low percentage of alcoholism. Venereal disease increased considerably and the loss of the canteen is blamed for this in part. The annual report of Surgeon-General Robert M. O'Reilly says in part, speaking of the above topics:

THE RACIAL ELEMENT.

The enrollment of about 5,000 native Filipino scouts having added a new racial element to the army, it becomes a matter of much interest to study the comparative effects of disease on them and on our white and colored troops. For the whole army, at home and abroad, during the year 1902, the white troops showed an admission rate of 1,706.33 per 1,000 and a death rate of 14.40. The negro troops had 1,897.74 admissions and 24.11 deaths per 1,000, and the Malay scouts 1,707.21 admissions per 1,000 and 24.04 deaths. The white race, therefore, gave the lowest figures in sickness and much the lowest mortality. The black race led in both, although the Malay closely approached it in death rate.

1. THE JOURNAL A. M. A., October 10, p. 920.

LITTLE DRUNKENNESS AMONG NATIVES.

The freedom of the Filipino from the vice of drunkenness is strikingly shown when we find that out of 5,000 men only three individuals were treated for alcoholism in one year, and that while white soldiers were admitted to sick report on account of their own misconduct in the use of alcohol at the rate of 24.78 per 1,000, and colored troops at the rate of 11.70, the Malay scouts showed the extremely small admission rate of 0.62 per 1,000.

MORE VENEREAL DISEASE.

The steadily increasing prevalence of venereal disease is the most discouraging feature in the sick report of the army. During 1902 13,000 admissions were from this cause alone, equivalent to a rate of 160.94 per 1,000. Admissions to sick report from alcoholism in 1902 were slightly in excess of the number (including volunteers) for 1901. A total number of 1,830 cases, equivalent to 22.65 per 1,000 of strength, occurred.

INCREASE DUE TO LOSS OF CANTEEN.

It is impossible not to attribute a large part of the steadily increasing venereal disease of the army to the loss of the canteen, where the soldier, if he so desired, could get his beer throughout the month, but was not subjected to the temptations to intemperance and vice now attendant on the expenditure of a full month's pay at the low resorts infesting the outskirts of our military reservations.

LESS INSANITY.

A slight diminution of insanity occurred in the army during 1902. There were 138 new cases, equivalent to the admission rate of 1.71 per 1,000, which is almost identical with the rate for the decade 1891 to 1900.

CANADA.

A new marine hospital is to be built at Louisberg, N. S., where it is needed because of the increase of shipping.

A New Hospital for Epileptics.—Work has begun on the new hospital for epileptics at Woodstock, Ont. It is expected that the buildings will be ready for occupation Aug. 1, 1904.

An epidemic of smallpox has broken out at Big Pond, a country settlement near Sydney, Nova Scotia. Eleven cases are so far reported, but the disease is said to be of a very virulent type.

Brandon General Hospital.—The new hospital at Brandon, Man., is being erected 36 by 89 feet, of stone and brick, with two stories and a basement. It will contain thirty-two beds and will cost about $25,000.

Progress Toward the Alexandra Hospital, Montreal.—Ground has been purchased and architects have been requested to submit plans for the erection of a complete infectious hospital of four pavilions to accommodate 100 patients.

Personal.—Dr. J. N. Waters, London, Ont., is to take up the work among the farming boys of Central India, succeeding the late Dr. Menzies, who died at Mhow recently, a victim of the plague. Dr. Waters attended Toronto University and graduated from Trinity Medical College.——Dr. Macdougall King, Toronto, has been appointed instructor of physiology in the medical department of the University of Denver.

Hotel Dieu Hospital, Montreal, Report.—There were treated in this hospital during the month of August 603 in-patients and 2,117 out-patients. Of the latter 1,117 were treated in the eye, ear, nose and throat departments. The following is the newly-appointed house staff of the Hotel Dieu: Senior house surgeon, Dr. Bourgeois, and Drs. Ludovic Verner, J. R. Hamelin, G. E. Bedard, Henri Prevost and Eugene Latreille.

FOREIGN.

Italian Congress of Internal Medicine.—The thirteenth Italian congress of internal medicine will meet at Padua, October 29. The questions announced for discussion are "Individuality in Pathogenesis and Etiology of Disease," "Immunity in Acute Infectious Diseases," and "Interruption of Pregnancy in Internal Diseases."

The Approaching International Congress of Gynecology.—It is announced from St. Petersburg that the date of this congress has been definitely set for September, 1905. The czar has taken the congress under his special charge and elaborate preparations will be made to render the fifth international congress a memorable one.

Another Monument to Charcot.—A handsome portrait bust and bas-reliefs have been erected at the French watering-place of Lamalou-les-Bains to the memory of Charcot. The bronze bust is the work of Madame Charcot. The memorial was dedicated with great ceremony on the occasion of the visit of the party of 120 physicians on the "Medical Study Trip" of 1903. The biographic and historic addresses are given in full in the *Progrès Médical*, September 26.

Prophylaxis of Venereal Disease Among Students.—The Prussian minister of public instruction has notified the faculties of the universities that steps must be taken to warn the students against the dangers of venereal disease to health and morals. He suggests as the most appropriate means short public lectures for the students in all departments of the universities, the lecturers to be from the faculties of medicine, philosophy and theology. These faculties are bidden to organize such courses at their earliest convenience. Our medical exchanges remark that the co-operation of the theologians might be dispensed with as the students know well enough the ethical side of the matter but choose to disregard it. The extent of the peril to health, however, is not known to most of them, and in this they need enlightenment.

France Enforces Destruction of Rats on Vessels from Infected Ports.—The French authorities have been aroused by the outbreak of plague at Marseilles to issue more stringent regulations. The alleged disinfection of the bales of rags from Constantinople having proved inadequate to prevent infection of the workmen handling them, the minister of the interior has decreed compulsory destruction of the rats on ships from infected ports. The measures against the rats can be undertaken during the voyage or after arrival before unloading. They must be by means of apparatus whose efficiency has been established by the national health department, and which are to be placed at the disposal of the officers of the ships on arriving, under the surveillance of the local boards of health. A certificate will be issued by the latter when the regulation has been complied with, and the ship may then proceed to unload. Lortet and Teissier have been writing to the Paris lay press urging the uselessness of quarantines as at present conducted if the rats are left unmolested. The generation of carbon dioxid has proved insufficient, as although it kills the rats it leaves the plague bacilli unharmed. They recommend the Clayton apparatus as the best adapted for the purpose. It generates gases fatal to animal life while not injuring nor fading goods. Marseilles is now declared free from the plague.

Benefits from Organization of the Profession at Munich.—The solid, united front presented by the members of the profession at Munich to the sick benefit societies, has resulted in a signal victory. Every society has agreed to their terms and demands. This includes the adoption of the American plan of free choice of a medical attendant, annual remuneration of 4 marks per capita and 12 marks per family ($1 and $3), and the organization of an "arbitration board" for each society, consisting of 2 physicians, 2 non-medical officers of the society and a lawyer not connected with the society. Extra demands on the physicians are to receive extra remuneration. The medical press is congratulating the Munich physicians for this remarkable victory, beyond their most sanguine anticipations. They urge united organization elsewhere as bound in time to produce equally favorable results. An entire column in the *Münch. Med. Wochft.* and almost two in the *Deutsche Med. Wochft.* are now devoted to warning ads cautioning outside physicians not to go to certain towns "without consulting the undersigned." The latter journal has nine such ads, all subsigned by one of the officers of the *Leipziger Verband.* The importance of the question in Germany may be estimated from the fact that 18 per cent. of the total population of the German Empire are compelled to belong to these sick-benefit societies, nearly ten millions in 1900. This is an average of 347.8 members to one medical attendant, and including the rest of the family, 695.6 individuals to each sick-benefit society physician.

Correspondence.

The Nickname "Allopath."

BALTIMORE, Oct. 5, 1903.

To the Editor:—Your editorial, with quotation from the *Boston Medical and Surgical Journal*, which shows that among "4,188 persons employed in the profession of medicine" in Massachusetts, "the number of physicians who are willing to answer to the nickname of allopath was 1,432," is startling, even though qualified by the suggestion that in some cases "an ignorant census-taker" may have been responsible for a wrongful classification. This narrow and restrictive misnomer, introduced in contemptuous terms by Hahnemann in his "Organon" in 1810, however repugnant to physicians in good and regular standing, we may charitably assume was not used in an offensive sense by the census-taker of the State Bureau of Labor Statistics. Not only to the illiterate, but, to a large extent, to the educated classes, the word conveys no significance

except in the negative way of contradistinction from homeopathy. But inconsiderate assent to such misleading characterization of rational medicine by "physicians who are not sectarians" is altogether another matter. Twenty-two years ago, in an essay on "The Prevalent Misuse of the Term Allopathy," read before the American Academy of Medicine, the writer took occasion to say:

> Well-educated and well-bred people, whom we can not charge with intentional discourtesy, whom we can not suspect of any disposition to wound our sensibility, so habitually use the word in common conversation that there is no hope of escape from the infliction except by revolutionary procedure. But this revolution must begin at home. We must aim the first blow of resistance at the foes of our own household. What only stirs our impatience with the unprofessional offender should provoke active resentment against the sinner in our own ranks. There are too many in the household of faith in the attitude of indolent acquiescence in the misuse of the word in question, and even of tacit acceptance of its implied reproach and its transparent falsity.

Similarly inappropriate and inconsistent in this age of unparalleled activity, progress and achievement, is the term "Old School" physician, which is still encountered in some parts of the country in the profession as well as out of it. What have we to do with the old except so far as it concerns the new? The leaders of thought and action are in the forefront of investigation, and the rank and file are imbued with the spirit of advancement. To apply such epithets as "allopath" and "old school" to the faithful workers who are patiently solving the intricate problems before us, who are emancipating medicine, the science and the art, from the mists and shadows, and widening it into the infinite capabilities of new life and larger liberty, is a form of perversity which is exasperating to say the least. And if, as appears from your significant quotation, there are those among us who do not properly resent the obnoxious "pathy" when applied to the comprehensive range and character of our professional objects and labors, and in whose ears such sophistical terms leave no jarring dissonance, there is evidently room for missionary work within our own ranks. So long as the profession itself submits to or winks at such misrepresentation there can be no terms of compromise, no middle ground of tolerance; all that is left is demand for unconditional surrender.

CHARLES C. BOMBAUGH, M.D.

Virginia Medical Society Proceedings.

ROANOKE, VA., Oct. 24, 1903.

To the Editor:—I observe in THE JOURNAL, October 3, that your reporter of the proceedings of the recent meeting of the State Medical Society of Virginia has got things a little mixed, and I hasten to make the correction: There were charges of various kinds preferred against "seven" of the Roanoke doctors, but it appears that not one of these charges was clearly sustained before the judiciary committee, and I can not understand why your reporter singled out my name and omitted the others. While it is true that when I located in this city three years ago I made a few professional announcements through a newspaper of my establishing a private sanitarium here, giving its location and objects, I fail to see wherein I violated in the least degree the true spirit of the Principles of Ethics, more especially since the Virginia State Medical Society permits business cards and professional announcements of private hospitals to appear in the newspaper.

BITTLE C. KEISTER, M.D.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

METHODS OF ITINERANT PRACTITIONERS.

OREGON, Sept. 30, 1903.

To the Editor:—Is it not in bad taste, if not a violation of the spirit of the Principles of Medical Ethics, for members of a state medical society to travel over the country, like traveling quacks, staying one day in a place every month, after giving notice through the local newspapers of the time of their coming? J. O.

STATES AND TERRITORIES RECOGNIZING DIPLOMAS.

NEW YORK CITY, Oct. 10, 1903.

To the Editor:—Please give a list of states and territories having no state board for examination of candidates wishing to practice medicine. Can you furnish it or inform me where to apply? S. G. J.

ANSWER.—The following states and territories recognize diplomas without requiring examination: Colorado, Kentucky, New Mexico, Nevada and Wyoming (also in one tribal division of Indian Territory). In New Mexico scrutiny of the diploma is very strict and only diplomas of a few of the leading institutions are accepted. In other states, as in Colorado, an examination is required if the diploma is not satisfactory, but the lines are not so closely drawn. We annually publish a little book entitled "Laws Regulating the Practice of Medicine in the Various States and Territories." The last edition is revised to July 1, 1903, and may be had for 30 cents.

PHYSICIAN'S WIFE CHARGED FOR LODGE EXAMINATION.

WISCONSIN, Oct. 9, 1903.

To the Editor:—Dr. A and Dr. B have always been on friendly terms. Dr. A is examining physician for an insurance and fraternal order that Dr. B and his wife wish to join. They go to Dr. A for examination, who does not charge Dr. B for his examination, but does charge Mrs. B. Is this in accordance with the Principles of Ethics? X.

ANSWER.—Sec. 2, Art. II of Chap. II of the Principles of Ethics says: "All practicing physicians and their immediate family dependents are entitled to the gratuitous services of any one or more of the physicians residing near them." This, however, refers to the services of one physician to another or to another's family in case of sickness; the case in point is more of a business transaction, and we see nothing unethical in Dr. A's charging for his services, if he so desires. Few physicians, however, would charge for the services mentioned.

Marriages.

OMAR BARTON PANCOAST, M.D., to Miss Joe Anna Ross, at Baltimore, October 1.

ROBERT SHERMAN KIRK, M.D., to Miss Alma Louise Seldler, both of Baltimore, October 1.

JOHN L. KIRKPATRICK, M.D., to Miss Maude Smith, both of Los Angeles, Cal., September 30.

HARRY ANDREWS COTTON, M.D., Boston, to Miss Alice Della Keys, at Baltimore, September 27.

FRED C. BLACKWELDER, M.D., Roswell, N. M., to Miss Mary Tutweiler of Indianapolis, October 7.

WINFIELD B. MARTIN, M.D., Freeport, Ill., to Miss Iona MacDonald of Chicago, September 30.

EDWARD J. FLEETWOOD, M.D., Wakefield, Neb., to Miss Inez E. Hultquist, at Osceola, Neb., September 16.

THOMAS B. CURRAN, M.D., Tacoma, Wash., to Miss Elizabeth Griggs Butler of Detroit, Mich., September 24.

JAMES LAWTON HIERS, M.D., Savannah, Ga., to Miss Elizabeth Meredith Maxwell of Omaha, Neb., October 7.

J. HAMILTON CHARTERS, M.D., Gaylord, Mich., to Miss Ethel Louise Chisholm of West Bay City, Mich., September 22.

H. HAYWARD STREET, M.D., Baltimore, to Miss Olivia S. Baldwin of Long Green Valley, Baltimore County, Md., October 1.

W. A. HEMINGWAY, M.D., a medical missionary of Shansi, China, formerly of Oak Park, Ill., to Miss Mary Williams, at Oxford, Ohio, October 1.

Deaths.

Joshua G. Allen, M.D. University of Pennsylvania, Philadelphia, 1856, died at his home in Philadelphia, September 26, from heart disease, aged 73. In 1863 he became visiting physician to the Philadelphia Lying-in Charity and Nurses' Home, which position he filled for thirty years. He was a member of the Philadelphia County Medical Society, Medical Society of the State of Pennsylvania, and the Philadelphia Obstetrical Society.

John H. B. Amick, M.D. University of Pennsylvania, 1876, a member of the Philadelphia Common Council for five years; inspector of drugs in the custom house during Harrison's administration, and during the Spanish-American War major-surgeon of the Nineteenth Pennsylvania Infantry, U. S. V.,

died at the German Hospital, Philadelphia, September 26, after an illness of ten weeks, aged 52.

Philo D. Patterson, M.D. University of Michigan, Ann Arbor, 1869, some-time president of the Michigan State Medical Society; a member of the American Medical Association, and the oldest practitioner in Eaton County, Mich., died at his home in Charlotte, September 27, from cancer of the throat, after an illness of several months, aged 60.

William H. Thomas, M.D. Medical College of Indiana, Indianapolis, 1876, a member of the faculty of his alma mater for two years, and later one of the founders of and a professor in the Central College of Physicians and Surgeons, died at his home in Indianapolis, September 30, from congestion of the brain, aged 70.

John Green, M.D. Charity Hospital Medical College, Cleveland, Ohio, 1867, a pioneer physician of Council Bluffs, Iowa, died at his home in that place from prostatic disease after an illness of more than a year, September 25, aged 71. He was a member of the Council Bluffs Medical Society.

Basil B. Brashear, M.D. Cleveland Medical College, died from ptomain poisoning at Upper Marlboro, Prince George County, Md., October 2, aged 81. He was a member of the faculty of Cleveland Medical College and chief surgeon of the Thirteenth Army Corps during the Civil War.

George Haven, M.D. Harvard University Medical School, Boston, 1883, instructor in gynecology in that institution; member of the Massachusetts Medical Society, died at his home in Boston, September 27, after a short illness.

Leven Cottingham, M.D. University of Louisville, Kentucky, 1882, member of the Henderson County (Ky.) Board of Health, died at his home in Robards, Ky., September 30, from dysentery, after an illness of ten days, aged 56.

Thomas P. Shepherd, M.D. Cleveland Homeopathic Medical College, 1899, of Cleveland, died at the Huron Street Hospital in that city, September 28, from toxemia following typhoid fever, aged 29.

Benjamin H. Milliken, M.D. New York University, 1863, died at his home in Bowling Green, Ky., after an illness of several weeks.

State Boards of Registration.

COMING EXAMINATIONS.

State Board of Medical Examiners of New Jersey, Trenton, Oct. 20-21.

Illinois State Board of Health, Great Northern Hotel, Chicago, Oct. 21.

Iowa State Board of Medical Examiners, Capitol Bldg., Des Moines, Oct. 21-22.

Louisiana State Board of Medical Examiners, Tulane Medical College Bldg., New Orleans, Oct. 26-27.

Oklahoma Medical Examining Board, Enid, Nov. 10.

Committee of the Connecticut Medical Society, City Hall, New Haven, Nov. 10.

Board of Registration in Medicine of Massachusetts, State House, Boston, Nov. 10-11.

State Board of Health of West Virginia, Point Pleasant, Nov. 10, 11, 12.

Nebraska State Board of Health, Lincoln, Nov. 11.

Medical Organization.

Indiana.

ELKHART COUNTY MEDICAL SOCIETY.—At the first fall meeting held in Elkhart, September 24, this society adopted the constitution and by-laws which had been so revised as to accord with those of the state and national organizations.

Iowa.

WOODBURY COUNTY MEDICAL SOCIETY.—This was organized, September 25, supplanting the smaller Sioux City Medical Society. There are forty physicians in Sioux City and twenty in the county outside of Sioux City and it is hoped to bring all these into the new society. The constitution and by-laws prepared by the American Medical Association were adopted, and the following officers elected, who will hold office until the regular election at the annual meeting on January 1.: Dr. Guy C. Rich, Sioux City, president; Dr. Charles Rice, Smithland, vice-president; Dr. Francis J. Murphy, Sioux City, secretary; Dr. Frederick A. Powell, Sioux City, treasurer, and Drs. Van Buren Knott, Milton Daily and John R. Savage, all of Sioux City, censors.

Kansas.

KANSAS STATE MEDICAL SOCIETY, SECOND DISTRICT BRANCH.—The Southeast Kansas Medical Society, at a meeting in Parsons, formally disbanded, and its members then organized as the Second District Branch of the Kansas Medical Society, which embraces Lyon, Coffey, Anderson, Linn, Greenwood, Woodson Allen, Bourbon, Elk, Wilson, Neosho, Crawford, Chautauqua, Montgomery. Labette, Franklin and Miami counties. The first meeting of the new society will be held in Fort Scott, December 1. By this change the members of the society are made members of the Kansas State Medical Society, which is auxiliary to the American Medical Association. The officers of the new society are: President, Dr. Millard F. Jarrett, Fort Scott; vice-president, Dr. John B. Anderson, Chetopa, and secretary, Dr. George S. Liggett, Oswego.

Louisiana.

FRANKLIN PARISH MEDICAL ASSOCIATION.—Franklin Parish physicians met at Winnsboro, September 24, and organized, with Dr. W. W. Lee, president; Dr. Lewis M. Griffin, Wisner, vice-president, and Dr. Charles L. Ramage, Winnsboro, secretary and treasurer.

Minnesota.

SIBLEY COUNTY MEDICAL SOCIETY.—This was organized at Arlington, August 25, with the following officers: Dr. David N. Jones, Gaylord, president; Dr. Milo E. Bushey, Arlington, vice-president; Dr. Robert R. Stoner, Winthrop, secretary; Dr. Ward Z. Flower, Gibbon, treasurer, and Drs. W. H. Lord, Henderson, Christ W. Kanee, Arlington, and John J. Langford, Green Isle, censors.

North Carolina.

RUTHERFORD COUNTY MEDICAL SOCIETY.—Dr. E. C. Register, Charlotte, N. C., met the physicians of Rutherford County at Rutherfordton and organized a county medical society with the following officers: Dr. Theodore B. Twitty, Rutherfordton, president; Dr. Romeo Hicks, Henrietta, vice-president; Dr. Edgar B. Harris, Rutherfordton, secretary and treasurer, and Drs. J. B. Thompson, Cliffdale, T. G. Hamrick, Caroleen, and Charles B. Wiseman, Henrietta, censors.

Texas.

TAYLOR COUNTY MEDICAL SOCIETY.—Physicians of the county met at Abilene recently and organized a county medical society with Dr. Bass of the State Epileptic Colony, president; Dr. Luther A. Grizzard, Abilene, vice-president, and Dr. J. B. Thomas, secretary.

BASTROP COUNTY MEDICAL SOCIETY.—This society was organized at Bastrop, September 24. The following officers were elected: Dr. H. Powell, Luckett, Bastrop, president; Dr. John H. E. Powell, Smithville, vice-president; Dr. Henry B. Combs, Bastrop, secretary and treasurer, and Drs. John H. E. Powell, Smithville, Nosco B. Harris, Redrock, and W. R. P. Thompson, Smithville, censors.

TYLER COUNTY MEDICAL ASSOCIATION.—Dr B. F. Calhoun, Beaumont, councilor for the Tenth (southeast) District, met with the physicians of the county at Woodville, and organized a county medical society with initial membership of twelve. Dr. William V. Stewart, Colmesneil, was elected president; Dr. John B. Roberts, Woodville, vice-president; Dr. Dru McMicken, Woodville, secretary and treasurer, and Dr. William P. Chapman, delegate to the state association.

Wisconsin.

SAUK COUNTY MEDICAL SOCIETY.—The physicians of the county met at Baraboo, September 24, and organized. The following officers were elected: Dr. Charles Gorst, Baraboo, president; Dr. James D. Trumbauer, Loganville, vice-president; Dr. George L. G. Cramer, Baraboo, secretary and treasurer, and Drs. Marshall T. Martin, Merrimack, Frank D. Hulbert, Reedsburg, and John Buehler, Prairie du Sac, censors.

IOWA COUNTY MEDICAL ASSOCIATION.—This society was organized at Mineral Point, September 23, with the following officers: Dr. William J. Pearce, Dodgeville, president; Dr. F. M. Bailey, Mineral Point, vice-president; Dr. Simon P. Deahofe, Mineral Point, secretary and treasurer; Dr. Thomas S. Lawler, Cobb, delegate to the state society, and Drs. William J. Pearce, Dodgeville, F. M. Bailey, Mineral Point, and Hugh F. McDonald, Hollandale, censors.

CHIPPEWA COUNTY MEDICAL SOCIETY.—Dr. E. L. Boothby, Hammond, councilor for the Eleventh District, met the physicians of the county at Chippewa Falls, September 29, and or-

ganized a county medical society, with an initial membership of 14. The following officers were elected: Dr. Charles A. Hayes, Chippewa Falls, president; Dr. Robert Cottington, Bloomer, vice-president; Dr. Robert B. Cunningham, Cadott, secretary and treasurer, and Drs. Hugh McCormick, Auburn, Herbert H. Hurd, Chippewa Falls, and Eugene P. Ellenson, Chippewa Falls, censors.

Society Proceedings.

COMING MEETINGS.

New York State Medical Association, New York City, Oct. 19-22.
Congress of State and Provincial Boards of Health of North America, Baltimore, Oct. 23-24.
American Public Health Association, Washington, D. C., Oct. 26-30.
Hawaiian Territorial Medical Society, Honolulu, Nov. 7.
Oklahoma Territory Medical Association, Oklahoma City, Nov. 11.

AMERICAN ELECTROTHERAPEUTIC ASSOCIATION.

Thirteenth Annual Meeting, held in Atlantic City, N. J., Sept. 22 to 24, 1903.

Under the presidency of Daniel R. Brower, M.D., Chicago, this association met in the Hotel Windsor, Atlantic City, its sessions being unusually well attended.

President's Address.

Dr. Brower, in his address, referred feelingly to the death of Dr. Robert Newman, a very prominent member and an officer, and the association passed resolutions testifying to the esteem in which he was held and the loss sustained in his death. Dr. Brower congratulated the association on the active interest being taken in electrotherapy, but he called attention to the ignorance of many practitioners concerning this agency, and urged that, in view of the wide use which it will soon receive, knowledge of the principles of the methods should be widely disseminated. Fundamental facts that have been established by expert experimentation should be known to all to prevent errors and useless research. Dr. Brower suggested that the terms "faradism," "galvanism" and "franklinism" should give way to scientific nomenclature.

Election of Officers.

The following officers were elected: President, Dr. A. D. Rockwell, New York; vice-presidents, Drs. Willis P. Spring, Minneapolis, and W. W. Eaton, Danvers, Mass.; treasurer, Dr. Richard J. Nunn, Savannah, Ga.; secretary, Dr. Clarence E. Skinner, New Haven, Conn. The next meeting will be held in St. Louis, Sept 13 to 16, 1904.

Dr. Francis B. Bishop said that he thought he had proved that the high frequency current could be made to penetrate glass and transmit metallic and liquid substances. He described his experiments and in the discussion the reliability of his deductions was questioned by several.

Dr. William J. Herdman, Ann Arbor, Mich., made a report for the committee on constant current generators and controllers.

Dr. Alfred W. Baylis, Buffalo, spoke of the need for special preparation for electrotherapy as a field of work, and compared the work done here and in the hospitals abroad.

The Effects of the Secondary Static Currents in Removing Albumin and Casts from the Urine.

Dr. Boardman-Reed, Philadelphia, read this paper, stating that it was common to find hyaline casts and albumin in the urine of patients who had been ill for some time with gastro-intestinal disorders, yet this form of renal affection was so amenable to treatment that he looked on it as an autotoxic nephritis dependent on indigestion. Following the lead of Dr. A. D. Rockwell he had subjected 18 such cases during the past year to electrical treatment, for the most part with the static wave current. Urinary analyses made before and after treatment demonstrated that such treatment exerted a distinct physical influence. Of the four cases reported in the paper, the albuminuria had been successfully controlled by static electricity.

DISCUSSION.

Dr. A. D. Rockwell cautioned against too much optimism with regard to this mode of treatment, stating that it was only occasionally that one met the mild forms that were suitable for such treatment. He believed that electricity acted beneficially by reducing congestion and increasing the blood pressure in the glomeruli.

Dr. William Benham Snow remarked that the wave current would act just as beneficially in these cases as the static induced if one took the precaution to use a sufficiently great spark gap, say four to six inches.

Dr. G. Betton Massey detailed an interesting case of glycosuria which he had controlled, so far as the glycosuria was concerned, by the use of static electricity.

Dr. A. D. Rockwell, New York, gave a paper presenting some theories concerning the action of electricity on the neurons.

X-Ray and Light in the Treatment of Tuberculosis.

Dr. Russell Herbert Boggs, Pittsburg, in this paper was of the opinion that these therapeutic methods were entitled to first place as adjuvants in the treatment of tuberculosis wherever located. He preferred to use a medium low tube with a coil, giving exposures of ten minutes on alternate days. With the static machine the treatment was more difficult and the dosage more uncertain. The tubes showed great individual variations, but the fluoroscope seemed to him to be the best test of the quality of tubes.

DISCUSSION.

Dr. Charles R. Dickson, Toronto, thought he had obtained fairly good results with the static machine.

Dr. William B. Snow said that if the static machine were operated so as to secure a sufficient volume of x-rays the results would be just as good as with the coil. He had proved the utter fallaciousness of the fluoroscopic test, and was, therefore, surprised to hear the author state that this was a better index of the quality of an x-ray tube than the spark gap.

Dr. Robert Reyburn, Washington, D. C., advanced the theory that the beneficial action of the x-ray in tuberculosis and cancer was due to the formation of an inflammatory product around the morbid cells, thus preventing further infection.

Dr. T. A. Pease reported a case in which he had successfully treated tuberculous glands of the neck by means of static electricity.

Dr. Francis B. Bishop agreed with the reader of the paper that, as a rule, better results were obtained with the coil, for, in order to secure good results with the static machine it must be run at very high speed in connection with a high vacuum tube. One could not get the same volume of current through the tubes with the static machine as with the coil. The speaker then reported three cases of tuberculosis which had apparently been cured by means of a convective discharge from "a cage" directed on the shoulders and chest. He could not accept Dr. Reyburn's theory, because it was known that if too long exposures were made at first there was great danger of causing general infection.

Dr. George Z. Goodell, Salem, Mass., said that after three months' treatment of a case of tuberculous adenitis of the neck with a current from the Kinraide coil and a spark gap of three inches, he was unable to observe any improvement.

Electricity in the Treatment of Chronic Deafness.

Dr. George Z. Goodell, Salem, Mass., presented his experience and those of others who had replied to his circular letter. Several had reported that a mild interrupted current relieved the tinnitus, but better results seemed to be obtained by the use of the continuous current with the positive pole to the ear. The exact value of electrolysis of the eustachian tube was not yet determined.

Employment of Static Electricity in the Treatment of Nervous Diseases.

Dr. William Benham Snow, New York, said that there were few nervous diseases that were not associated with inflammatory processes and failure of nutrition. Such conditions

were best met, in his opinion, by the use of the wave current. In acute neuritis he employed as long sparks as possible along the affected nerve, and in chronic neuritis the sparks were applied over the area in which they caused the most pain. Excellent results could be obtained in the very early stages of anterior poliomyelitis from electrical treatment.

DISCUSSION.

DR. R. J. NUNN, Savannah, Ga., spoke of the therapeutic possibilities of radium, and expressed the belief that all electrical currents presented vibrations, and that the lower vibrations simply served as diluents of the higher ones.

DR. CHARLES O. FILES, Portland, Me., was of the opinion that the curative action of electricity was dependent on its ability to relieve all forms of congestion.

A Year's Work in Electrotherapy.

DR. LAURA V. GUSTIN-MACKIE, Attleboro, Mass., read this paper, which embodied a clinical experience of 125 cases. She spoke of the great relief that she had observed from the use of electricity in anemic women suffering from ovarian pain and various pelvic disturbances.

Electrical Treatment of Trachoma and Corneal Opacity.

DR. MARGARET A. CLEAVES, New York, presented in this paper the history of a severe and neglected case of trachoma that she had successfully treated by zinc electrolysis. During a period of 3½ months she gave 37 electrical applications, using a current of 2½ milliamperes for two minutes at each sitting, and an indifferent of 11 square inches at the nape of the neck. Improvement was noted within ten days. The boy had been discharged cured in June, 1896, and in October of the same year treatment of the corneal opacity was begun, using cathodal electrolysis and one milliampere of current for from one to three minutes three times a week. The boy now has a good position in the business world, whereas but for the treatment he would have become a public charge.

The Successful Treatment of Eighteen Cases of Granular Lids by the X-Ray and High Frequency Vacuum Electrodes.

DR. ALBERT C. GEYSER, New York, had made exposures of four or five minutes every other day for two or three weeks, and had then used the high frequency current to improve nutrition.

Exophthalmic Goiter and Its Rational Treatment.

DR. FRANCIS B. BISHOP, Washington, D. C., presented this paper on Wednesday morning. He believed that the early and continued use of the corset was a prominent factor in the etiology of this disease, and that, as a part of the treatment, it was highly important to remove all pressure from the abdomen and secure deep breathing. It was also essential that these persons should have an abundance of rest and of nitrogenous food. Medication had proved a delusion and a snare, but much benefit resulted from electrical treatment. He made use of the continuous current, gradually increased up to the point of toleration, and regulated in accordance with its effect on the pulse. A large sponge electrode should be connected with the positive pole and placed high up on the neck, and two sponge electrodes, connected with the negative pole, should be placed on either side of the neck over the pneumogastric nerves and the thyroid. After such an application for ten or fifteen minutes the patient would be quieted, and the current should then be applied directly to the gland for the same length of time, the sittings being on alternate days.

DR. T. A. PEASE, Norwood, N. Y., claimed much for his method, which consisted in blanching the skin by the cataphoric use of a 4 per cent. solution of adrenalin, and then applying the high frequency current with a wooden electrode.

DR. A. D. ROCKWELL, speaking from a long and large experience with this affection, advised the use of the galvanic current in considerable strength, applying it by means of large clay electrodes over the ciliospinal center and the solar plexus.

DR. WILLIAM W. EATON, Danvers, Mass., had had a favorable experience by practically the same method as outlined by Dr. Rockwell.

DR. WILLIS P. SPRING, Minneapolis, asked for experience as to the effect of using the fluoroscope on the operator's eyesight.

DRS. W. J. HERDMAN and C. R. DICKSON said that it caused marked deterioration of the vision.

DR. LORING, Boston, said that a simple and efficient means of protecting the eyes was by attaching a thick piece of glass behind the fluoroscopic screen.

DR. R. J. NUNN suggested that this glass shield should be selected only after testing its opacity to the *x*-ray.

Zinc-Mercuric Cataphoresis of Tuberculous Glands.

DR. G. BETTON MASSEY, Philadelphia, described his method, and exhibited two patients that had been so treated. He employs for the active electrode a sharpened sliver of amalgamated zinc, which, except for the first treatment, is insulated nearly to the tip. The first puncture is made with a Hagedorn needle. A current of one to three milliamperes is allowed to flow for half an hour, and the treatment is repeated three times a week. It was worthy of note that not only is the local process cured but the patient's general condition is decidedly improved.

A Plea for Electrotherapeutics Proper.

DR. WILLIAM J. HERDMAN, Ann Arbor, Mich., urged the association to resist the temptation to run after fads and indulge in borderline studies. He rehearsed the manifold therapeutic properties of the various currents.

Radiant Light Baths in the Treatment of Neuroses.

DR. THOMAS D. CROTHERS, Hartford, in this paper, was even more enthusiastic than in his paper of one year ago. Increasing experience showed that not only was the radiant light bath more acceptable to the patient, but observations on the pulse, temperature and influence on the secretions proved the superiority of the light bath.

DR. CHARLES H. SHEPARD, Brooklyn, advocated the use of electricity in conjunction with the hot-air bath.

DR. W. J. HERDMAN warmly seconded this suggestion, arguing that the stimulant effect of the induced current was an admirable corrective of the debility necessarily produced by the hot-air bath.

Radium, with a Preliminary Note as to Its Therapeutic Uses in Cancer.

DR. MARGARET A. CLEAVES, New York, said that there were three distinct types of rays emanating from radium, viz.: the *a*-rays, representing the major portion, and presenting some of the characteristics of the *x*-ray; the *b*-rays, which are much longer and correspond to the cathode rays, and the *r*-rays, which have a still higher rate of vibration. As one of the pioneers in the therapeutic use of radium, Dr. Cleaves reported two cases that she had treated with the aid of one gram of radium of 7,000 radioactivity, i. e., having 7,000 times the radioactivity of uranium.

The Present Status of X-Ray Therapy in the Management of Cancer.

DR. CLARENCE E. SKINNER, New Haven, Conn., read this paper, saying that the *x*-ray was one of the best means for the treatment of malignant disease, because as large a proportion of cures and as small a proportion of recurrences during a given period had been obtained with it as with any other means. It was now generally believed that in the early stages malignant disease should be removed by the knife, and that this should be followed by a thorough course of *x*-ray treatment. Whether or not, as some seem to think, the *x*-ray actually hastened metastasis could not be stated positively, but the evidence seemed to be against such a view.

Report of Committee on Current Classification and Nomenclature.

MR. WILLIAM J. JENKS, E.E., presented this report on Thursday, urging the substitution, so far as possible, of the terms "constant current" for "galvanic current," and "induced" or "magnetic induced current" for "faradic current."

Perineuritis.

DR. A. W. BAER, Chicago, pointed out the fact that an electrical application constituted a good means of differentiating

between facial neuralgia and suppuration at the root of a tooth.

Other papers read were: "Clinical Report on the Use of the X-Ray in Lesions of the Spinal Cord," by Dr. C. W. Daniels, Savannah, Ga.; "Currents of High Frequency, Apparatus and Therapeutic Uses," by Dr. F. G. DuBose, Selma, Ala.; "The Roentgen Ray as an Aid in Diagnosis," by Dr. Herman Grad, New York; "A Plea for an Accurate and Scientific Method of Roentgen Ray Treatment," by Dr. M. K. Kassabian, Philadelphia.

Cases were also reported: Eight of advanced cancer, by Dr. W. W. Eaton, Danvers, Mass.; one of asthma with fibroids and pelvic adhesions, by Dr. C. A. Covell, Syracuse; several of malignant growths, by Dr. M. M. Johnson, Hartford, Conn.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

Sixteenth Annual Meeting, held in Chicago, Sept. 22-24, 1903.

(*Concluded from page 925.*)

Shortening of the Round Ligaments by the Blunt Hook Method.

Dr. H. W. Longyear, Detroit, described this method as follows: "The location of the internal ring is determined by finding the point of crossing of Poupart's ligament and femoral artery, as the ring is situated immediately back and above it. Beginning half an inch inside this point and cutting toward the pubic end parallel to Poupart's ligament, a one-inch incision is made through skin, fat and superficial fascia. Eye retractors and blunt hooks are then used, the tissues separated down to the aponeurosis of the external oblique, which is thus laid bare to the eye, to the extent of about one square inch. A puncture is now made through this aponeurosis one-quarter of an inch long, situated just above Poupart's ligament and to the back of the square inch of cleared aponeurosis, and through this the blunt hook is inserted and the ligament drawn out, usually with more or less of the fat of the canal along with it. The ligament is isolated and its fibrous attachments stripped back toward the internal ring with blunt-pointed dressing forceps, the ligament drawn out to the necessary length, an aneurism needle passed through the aponeurosis and the loop of ligament drawn through this, folded back on itself, and, with one stitch of kangaroo tendon, made fast, the suture embracing in its grasp the edges of the aponeurosis where the ligament first passes through it, half of the ligament at the same point and half on each side of the loop that is folded back on it. The skin is then closed by a running catgut suture, and dressings applied. The operation is applicable only to cases of mobile uteri without diseased appendages, in which cases it is an ideal procedure, or to cases in which adhesions may have been previously broken up by abdominal section."

Of 58 cases operated on by this method, late examination has shown the uterus to be in normal position in 48; 6 other cases were normal two to five months after operation, and were then lost sight of; there was 1 partial failure and 2 complete failures.

DISCUSSION.

Dr. Edward J. Ill had done this operation twelve times and, while the uteri remained in place, the painful scars made trouble.

Dr. Albert Goldspohn, Chicago, said the objections to the simple Alexander operation were that it was not thorough and it did not fulfill all the indications. He then mentioned his own method.

The Need for Study of the Symptoms of Perforation in Typhoid Fever, and the Life-Saving Possibilities of Early Operation.

Dr. W. D. Haggard, Nashville, Tenn., stated that only about three hundred cases of operation for intestinal perforation in typhoid fever had been reported since the first case in 1884. Granting that this represented only one-half or one-fourth, the number is pitifully meager when it is computed that twenty-five thousand persons die yearly in the United States from perforation and peritonitis in typhoid fever.

He made a plea for an early diagnosis and an attempt to save a part of this appalling number. On a basis of a possible 30 per cent. recovery, which was shown to have been attained in the reported cases, 7,500 lives might be preserved yearly by prompt operation. The difficulty lies in making an early diagnosis. The abdomens of typhoid cases should be exposed and carefully examined daily. No abdominal symptom or sign should be considered trivial. Pain was usually the first note of alarm—sudden, severe, colicky and persistent. Exploratory laparotomy, under cocain if necessary, was earnestly urged as a diagnostic measure in suspicious but doubtful cases. A plea was made for recognition and interference with the early and mild symptoms. The surgeon should stand in close relationship with the physician in all typhoid cases, as is done in appendicitis.

Dr. Haggard reported three successful operations and described the technic.

DISCUSSION.

Dr. John B. Murphy had operated on two cases of peritonitis with typhoid fever without perforation. Both recovered.

Dr. Robert T. Morris said the general practitioner must feel impelled to call a surgeon to his aid in almost any case of typhoid, not necessarily for operation, but for consultation. In a case of simple peritonitis from extension of the infection, the patient should be relieved by opening the abdomen and draining. Hemorrhage in typhoid fever cases is dangerous and has not received the attention it deserves. He predicted that in the next decade hemorrhage in typhoid cases would be treated surgically.

Dr. Willis G. McDonald said that the classical description presented in text-books of intestinal perforation in typhoid fever was misleading. It was rather a fine description of impending death.

Dr. Lewis S. McMurtry, Louisville, Ky., delivered the "Memorial Address on Dr. William E. B. Davis of Birmingham, Ala.," paying a high tribute to an earnest, honest, able and intense man, who, dying before the age of forty years, had done the work usually encompassed in a good long life.

Some of the Sources of the Disappointments of the Surgeon.

This was the title of the president's address, delivered by Dr. L. H. Dunning, Indianapolis. He urged the importance of not making an unwarrantedly favorable prognosis. New methods need the test of time ere there is too much dependence placed on them. The most nearly perfect surgeon is one who orders his life with the utmost care, but disappointments in greater or less degree will come to all surgeons, be they ever so successful, for it seems to be the natural order of things that contrasting or antagonistic elements shall exist side by side. The man who becomes despondent and inactive because of this is the weak man. The strong man will endeavor to magnify the good and crush out the evil. The surgeon's hope should be to eliminate every preventable source of failure and, when failures do come, to make of them task masters compelling the way to better things.

The Rational Treatment of Postpartum Infections of the Uterus.

Dr. D. Tod Gilliam, Columbus, Ohio, after discussing the bacteria concerned, called attention to the fact that a recently delivered uterus is an excellent culture ground for infection, being filled with the juices of disintegration and spilled blood. The mortality would be appalling were it not for the safeguards. These are: 1. Autosterilization of the genital tract. 2. The protective epithelium. 3. The protective leucocytes under the epithelium. The germ of Döderlein is the principal agent in sterilizing the genital tract; hence irrigation before or after labor is harmful, because it washes this germ away and does not entirely rid the tract of pathogenic germs. The normal death rate of puerperal infection is about 1 per cent., but after curettage it amounts to 20 per cent. The sharp curette is especially dangerous, as it not only fails to remove the germs, but destroys the protective barriers. As it is impossible to say that streptococcus infection is not present in any case, the only safe way is to eschew the sharp curette entirely in puerperal infection. Curettage is only permissible where there is known to be

fetal debris in the uterine cavity, and where there is reason to believe no streptococci are present. For this the finger or dull curette with stiff handle should be used. Flushing, if done at all, should be done with every precaution against infection. The patient should be on a table, under a good light, the vulva and vagina cleansed, the latter with 5 per cent. creolin in liquid green soap, mopped, dried and retractor introduced; the cervix grasped, drawn down and steadied with forceps; the cervical canal wiped out with gauze and bits of membrane picked off with forceps. Gently introduce irrigator and flush. If pulse and temperature drop, repeat daily or oftener, otherwise discontinue.

"Penetrating and Perforating Gunshot and Stab Wounds of the Abdomen" was the title of a paper by Dr. John Young Brown, St. Louis, which went fully into the literature and reported cases.

The Use of the Stem Pessary for Infantile Uteri, Scanty Menstruation, Amenorrhea and Dysmenorrhea.

DR. J. HENRY CARSTENS, Detroit, explained the theory that since weak or poorly developed muscles can only be strengthened by constant exercise, the only way to exercise the uterine muscles is to introduce something into the uterus, and the constant tendency to expel the contents will enlarge the muscles and develop the uterus. It is absolutely essential that no pelvic trouble, either chronic or latent, exists and the diagnosis must be perfect. He uses the Chapman hard rubber pessary and leaves it in from six months to two years. He cited cases showing relief secured by this method.

"Tuberculosis of the Female Genitalia and Peritoneum" was the title of a paper by Dr. John B. Murphy, Chicago, which considered in detail all the varieties.

Movable Kidney with Secondary Cyst Formation, Resembling Ovarian Cyst.

DR. RUFUS B. HALL, Cincinnati, argued against the almost universal practice not to interfere until compelled to do so. He contends that if the cases of movable kidney are operated on early for fixation of that organ, it will save structural changes and give great relief from invalidism. Movable kidneys, if neglected, may undergo cyst formation or develop hydronephrosis or pyonephrosis, as in the cases reported.

DR. N. STONE SCOTT, Cleveland, Ohio, read a paper on "Surgery of the Ileocecal Valve for Malignant Disease," and reported cases.

The Choice of Methods for Closing the Parietal Abdominal Incision.

DR. EDWIN RICKETTS, Cincinnati, thought that the through-and-through sutures of silkworm gut with the midway closure of the peritoneum with interrupted sutures of fine silk is nearer to the ideal method than any other. Silkworm gut is actually impervious to any attacks of infection.

Supravaginal Amputation for Fibroid Tumors.

DR. HERMAN E. HAYD, Buffalo, N. Y., wished to place himself on record as believing that the supravaginal amputation for necessarily operable fibroids meets nearly every indication and has been applied to every conceivable kind of tumor, with short or long pedicle, tumors growing deep into the pelvis or out into the broad ligaments, and with results which make it a clean and ideal piece of surgery. It is the operation of choice, excepting in those cases where drainage must be provided for or where the cervix, for various other reasons, should be removed.

The Pelvic Musculature in Disease.

DR. HUGO O. PANTZER, Indianapolis, read this paper, narrating two extreme cases in detail. In one, during a subperitoneal hemorrhage involving both broad ligaments, the muscles of the pelvic floor were in spastic, painful contraction. This symptom has been found available in differential diagnosis between pelvic hematoma and hematocele. In the second case similar contraction was observed in a case of gangrenous appendicitis.

Veratrum Viride in Surgical and Obstetrical Practice.

DR. CHARLES L. BONIFIELD, Cincinnati, in this paper said that veratrum stimulates the liver, kidneys, skin and salivary glands, lowers temperature and relieves inflammatory pain by its effect on the circulation. These properties make it valuable in localized peritonitis and in salpingitis. In appendicitis the appendix should, if possible, be removed during the first twenty-four hours. When this can not be done the Ochsner treatment should be given, supplemented by the hypodermic administration of veratrum. In the treatment of postoperative peritonitis, after the very important free purgation has been secured, the heart, by its exceedingly rapid action, may exhaust itself before convalescence can be established. In this condition there is no drug equal to veratrum. It is superior to strychnin or digitalis because, while they may stimulate the heart to act for a time with renewed vigor, veratrum makes the work of the heart easier and gives it a chance to rest between beats.

Veratrum has been used for thirty years in the treatment of eclampsia by a considerable number of practitioners without a fatality, and every one who has given it a thorough trial acknowledges it to be superior to chloroform, morphin or any other drug in general use.

Ovarian Grafting.

DR. ROBERT T. MORRIS, New York, detailed some progress in experimental work and then took up the use of the procedure in human subjects. At the present time he had reached this point: (1) If the ovaries and oviducts have to be removed *en masse*, the patient will suffer from a precipitate menopause if she is left without an ovary. If a piece of ovary be taken from this patient or from another operated on at the same time, put in a salt solution at a temperature of 100 F., and then grafted in the broad ligament, that patient will continue to menstruate and to have the comfort that goes with the possession of an ovary. But if an ovary be grafted from another patient, at the end of a year perhaps the grafted ovary will have practically disappeared and her menopause begin. If a woman be grafted with a piece of her own ovary, the menopause may not begin for some years afterward, or until the normal time for it. This is a practical point, he said, which surgeons can apply in their everyday work. (2) A patient grafted with a piece of her own ovary may become pregnant if a tube and oviduct on one side be left, or part of it on one side. A patient grafted with a piece of an ovary from another patient may become pregnant, if pregnancy occurs quickly. (This has occurred twice with rabbits during his experimentation.) But pregnancy must occur before degeneration has gone to such a point that the ova are not well formed. He expected to obtain further good results.

DISCUSSION.

DR. D. T. GILLIAM, Columbus, Ohio, inquired what kind of suture was used.

DR. MORRIS replied that he uses the very smallest No. 1 catgut.

DR. JOHN B. MURPHY asked how Dr. Morris places the ovary in the abdomen. He said he had removed one ovary in connection with a fibroid tumor and transplanted it into a monkey. He split the ovary, transplanted half of it subperitoneally and the remaining half intraperitoneally. He removed it thirty-two days afterward, and sent it to the pathologist, without any statement as to what was done, and asked for an opinion as to the condition of the ovary. The pathologist reported that the ovary was absolutely normal in every respect.

DR. HERMAN E. HAYD said that if the processes of ovulation and menstruation will go on whether an ovary be transplanted intraperitoneally or extraperitoneally, there will be infinitely less danger if the piece of ovary was transplanted into the abdominal wall. In other words, one need not worry about his technic if menstruation will go on just the same.

DR. MURPHY said the transplantation of an ovary intraperitoneally is fatal. The peritoneum will eat rapidly everything brought in contact with it.

DR. ALBERT GOLDSPOHN said that he had not utilized ovarian tissue that had been completely severed from its original connection, fearing that it might seriously interfere with function.

In one case he used only a slight vestige of an ovary. It looked like a mass of denuded raw connective tissue, although there was ovarian tissue in it. The remnants were poorly connected with a little bit of connective tissue. In another instance there was more connective tissue. He swung the fragment around to the nearest accessible healthy peritoneal surface and stitched it with fine catgut. Both women menstruated; one for two months and the other regularly ever since. The latter is enjoying very good health. There seems to have been no difference caused in the sexual appetite.

Dr. James F. Baldwin asked if the ovarian transplantation is to prevent the menopause, and not with the idea of future pregnancy, this being of minor importance, why may we not, in a patient who has been operated on several months before, make an incision down to the peritoneum, make the little pocket and drop in the healthy ovary from patient No. 2, and close the incision? Frequently an ovary may be embedded in the densest adhesions in the pelvis, the woman has gone on menstruating, but has not conceived. It seemed to him that an ovary is in the peritoneal cavity only for pregnancy.

Dr. Morris said that the corpus luteum controls menstruation. So long as a corpus luteum is formed in a grafted ovary the patient will menstruate. When a corpus luteum is not developed then the patient ceases to menstruate. This explains why menstruation is more temporary when an ovary is transplanted from another person; it degenerates after a time, being foreign to the organism into which it is transferred. Dr. Morris said it was necessary to get a lymph circulation in order to keep the ovary alive. Were it not for this lymph circulation the ovary would become absorbed, because the peritoneum will digest beefsteak. In a few days a complete ovarian circulation is established. He has seen pretty good sized arteries surrounding a grafted ovary, but not actually in it. A nurse who had had her ovaries removed two years previously, and who had ceased menstruating, menstruated regularly for several months after an ovarian grafting. A young woman with an infantile uterus, after receiving an ovarian graft, menstruated for a year. The graft then became absorbed and menstruation ceased. This is a new line of work, and while there may be some disappointments, practical points are being brought out that are going to be of great value.

Dr. F. F. Simpson, Pittsburg, Pa., read a paper entitled "A Consideration of Combined Ectopic and Intrauterine Pregnancy, with Report of a Case." He analyzed the case and said that the common errors in diagnosis have been (a) the recognition of the uterine pregnancy and mistaking the ectopic for an inflammatory condition or neoplasm; (b) the recognition of ectopic and overlooking the uterine pregnancy. Accompanying the paper is a table of 118 cases from literature.

Emergency Abdominal Surgery at the Patient's Home—A Demonstration.

Dr. Willis G. MacDonald, Albany, said that operation in the patient's home becomes a necessity in many conditions—as in intestinal perforation—and the surgeon must be prepared to treat such emergencies without delay and yet under aseptic conditions. He discussed the various details.

Ectopic Pregnancy.

Dr. Henry D. Ingraham, Buffalo, reported twelve cases operated on. After careful serial microscopic examination he was inclined to think that previous inflammation of the tube had but little to do in causing ectopic pregnancy. The only condition discovered that could be the cause was the case of constriction of the tube, the cause of which at present was unknown.

PENNSYLVANIA STATE MEDICAL SOCIETY.

Fifty-third Annual Meeting, held at York, Sept. 22 to 24, 1903.

(*Continued from page 926.*)

Streptococci and Antistreptococcus Sera.

Dr. D. H. Bergey, Philadelphia, read a paper in Section A on September 24, in which he stated that the recent studies with the antistreptococcus sera appear to demonstrate that such streptococci can not be regarded as the etiologic factors of such diseases as acute articular rheumatism, scarlet fever and smallpox, as had been claimed by different investigators.

Some Points on Appliances for Bacteriologic Work by Busy Country Doctors.

Dr. A. C. Wentz, Hanover, spoke extemporaneously, addressing some very valuable remarks to the country practitioner. He exhibited a number of valuable devices for the office which is not provided with a laboratory.

The Necessity for the More Careful Instruction of Medical Students in the Diagnosis of Preventable Diseases.

Dr. Benjamin Lee, Philadelphia, felt that the tendency with both student and instructor was to devote too much attention to therapeusis and not enough to diagnosis. The large increase in diphtheria he believed largely due to the failure of physicians to differentiate between this condition and follicular sore throat or tonsillitis. The same was remarked of scarlet fever. In smallpox lies the greatest importance of early diagnosis. Students should be compelled to study all these diseases.

DISCUSSION.

Dr. J. M. Anders agreed with the above statements and cited the fact that in Philadelphia, through the courtesy of Dr. Welch and of the Board of Health of Philadelphia, the students of the various medical colleges have abundant opportunity to observe this class of diseases in the Municipal Hospital.

Dr. Seneca Egbert emphasized the value of personal observation of these diseases. He stated that the Philadelphia students are required to release the city and the board of health from liability in case of infection, and are required to disinfect their persons before leaving the wards.

The Effect of an Improved Municipal Water Supply on the Prevalence of Enteric Diseases.

Dr. J. Frank Small, York, gave statistics and urged that efficient filtration of a municipal water supply has a decided effect in lessening the prevalence of enteric disease.

DISCUSSION.

Dr. Seneca Egbert believed that the demonstration given by Dr. Small should be repeated in every city in the state. He felt that the people do not appreciate the need of pure water.

Dr. D. H. Bergey felt that if the trouble were taken to make a detailed investigation, other sources of infection would be found in every case of typhoid fever, e. g., milk, etc.

Dr. J. V. Kelly, said that in 52 cases in the Twenty-first Ward, 27 were traced to one milkman.

A Contribution to the Clinical Study of Cerebrospinal Meningitis.

Drs. Thomas C. Ely and J. J. Snyder, Philadelphia, reported a series of 23 cases, sailors from the U. S. Training Ship *Minneapolis*. A notable feature was the vagueness of symptoms in some instances. Only in epidemics, they stated, would these cases have been classified, and the fact leads to the query whether sporadic cases are not often overlooked, just as doubtless cerebral pneumonias and cerebral typhoids are improperly classified as sporadic cases of cerebrospinal meningitis.

DISCUSSION.

Dr. A. O. J. Kelly, Philadelphia, called particular attention to the toxic nature of some of the symptoms. He hoped that in the future it would be possible to separate similar pathologic lesions of diverse etiology.

A case of "Aneurism of the Left Subclavian Artery Treated by Wiring and Electrolysis" was reported by Dr. Judson Daland, Philadelphia. Death occurred in 20 days. Dr. Daland believes that this operation is worthy of trial when medical treatment fails, and that the percentage of success will be greatly increased if the operation be not performed as a dernier resort.

Typhoid Fever.

Dr. L. B. Kline, Catawissa, called attention to the increasing ravages of typhoid fever. Comparison with other acute and infectious diseases shows a higher number of cases and a larger death rate for typhoid fever. He approves of the main-

tenance of the intestinal tract in an aseptic condition. Coal-tar products should be interdicted.

DISCUSSION.

DR. A. O. J. KELLY stated that when there were severe toxic effects with great exhaustion, diminution in the urine, etc., the greatest benefit was to be derived from hypodermoclysis. Those cases not so profoundly toxic are given the greatest benefit by enteroclysis. He emphasized the great value in toxic conditions of normal salt solution.

The Need of a Ward in the General Hospitals for the Treatment of the Mildly and Curably Insane.

DR. H. W. RHEIN, Philadelphia, in this paper said that many cases of mild and incipient insanity which can not be treated at home should, instead of having to go to an insane asylum, be treated in a special ward in the general hospital, under the care of an alienist, who should be a member of the staff of the hospital.

The Dietetic Treatment of Chronic Nephritis.

DR. J. M. ANDERS read this paper, stating that a dietary is inadequate if it fails to meet the requirements of nutrition plus the loss of albumin. Proper diet is vital. To lessen albuminuria at the expense of the quality of the blood and general nutrition is very unwise. He allows red meats and fats and butter (except in obesity). Whole milk should be a considerable portion of the diet. Meats should be somewhat restricted, while fruits and green vegetables and rice may be given rather freely. He emphasized the fact that the normal daily physiologic quantity of food is required, which is practically 110 to 130 grams of albumin, 350 to 400 grams carbohydrates, 75 to 110 grams of fat, 2,500 to 3,000 grams of water, and 18 to 30 grams of inorganic salts. The importance of carefully recording the bodily weight of the patient is also emphasized, and systematic blood examinations are urged.

DISCUSSION.

DR. THOMAS D. DAVIS, Pittsburg, said he had been successful in giving milk in a cup instead of a tumbler to patients, who feel that they can not take milk, and the addition of some vanilla and a bit of ice rendered the milk more agreeable.

DR. JOHN H. MUSSER reported a case of typhoid fever seen in relapse, not operated on because of the condition of the patient, who afterward recovered. This was discussed by Drs. W. J. Middleton, F. V. Swing and R. H. Gibbons.

Symposium on X-Ray Therapy.

At the Wednesday morning session of Section B Dr. George W. McNeil, third vice-president, presiding, a paper on "*X*-Ray, Light and High Frequency Electricity" was read by Dr. Russell H. Boggs, Pittsburg, in which he gave a detailed consideration of the whole subject.

"Utility of the *X*-Ray for the Treatment of Chronic and Malignant Diseases of the Skin and Superficial Tissues" was read by Dr. Samuel H. Heller, Lancaster, who believed that deleterious results are due to improper technic and detailed some of his own cases.

"Roentgen Rays as a Palliative in the Treatment of Cancer" was the title of a paper by Dr. C. L. Leonard, Philadelphia. He advocated this method postoperatively and in inoperable cases. He emphasized the value of perfect technic and credited many of the failures to improper application.

DR. MIHRAN K. KASSABIAN, Philadelphia, read "Roentgen Rays in Therapeutics," a thorough presentation of the subject. He recommended the preservation of careful statistics of all cases treated.

DISCUSSION.

These papers were discussed by Dr. Taylor, Philadelphia, who reported a case, and by Dr. Lewis H. Taylor, Wilkesbarre. Dr. Leonard said he had secured excellent results in the treatment of neuralgia and neuralgic headaches.

"Some Problems in Surgery" was read by Dr. George D. Nutt, Williamsport.

DR. WILLIAM H. BEACH, Pittsburg, read a paper on "Proctocolitis, with Special Reference to Treatment." He gave in detail the diet and medication advised, and felt that surgical relief should be resorted to only in extreme cases. In the discussion, Dr. John G. Clark, Philadelphia, recommended the method of Weir of draining the colon through the appendix.

(To be continued.)

COLORADO STATE MEDICAL SOCIETY.

Twenty-third Annual Session, held in Denver, Oct. 6 to 8, 1903.

The beneficial effect of the recent reorganization made itself manifest by a large attendance of members, both from the city of Denver and from the counties all over the state. From the point of numbers and enthusiasm it was the most successful meeting ever held in the state. The constitution was so amended that only members of county societies may hereafter become members of the state society. The section referring to membership of graduates from sectarian colleges was amended by inserting the following proviso: "and who is not affiliated with a sectarian college or society." Resolutions were passed to request President Roosevelt to appoint a physician on the Panama or Nicaraguan Canal Commission.

The most far-reaching action taken by the society was the resolution to establish a state medical journal. The editor was elected, Dr. Edward Jackson, who was at one time the editor of the *Pennsylvania State Medical Journal.*

The election of officers resulted as follows: President, Dr. Thomas H. Hawkins, Denver; vice-presidents, Drs. J. Tracy Melvin, Sagauche, A. C. Friedman, Colorado Springs, and R. F. Graham, Greeley; delegates, Drs. Sol. G. Kahn and W. A. Jayne; councilors, Drs. C. F. Gardiner, Colorado Springs, and S. D. Hopkins, Denver; secretary, Dr. J. M. Blaine, and treasurer, Dr. W. E. Rothwell; publishing committee, Drs. Edward Jackson, Robert Levy and S. E. Solly.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Twenty-ninth Annual Meeting, held at Memphis, Oct. 7 to 9, 1903.

The following officers were elected for the ensuing year: President, Dr. Hugh T. Patrick, Chicago; vice-presidents, Drs. Bransford Lewis, St. Louis, and George W. Cale, Springfield, Mo.; treasurer, Dr. Thomas Hunt Stucky, Louisville, Ky., re-elected: secretary, Dr. Henry E. Tuley, Louisville, Ky., re-elected. The time and place of meeting were left to the president, secretary and treasurer to decide. A report of the other proceedings will be given next week.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Bromipin by the Bowel.

Rahn, in *Ther. d. Gegenwort,* recommends the use of bromipin, administered per rectum, to infants. He advises it in doses of one grain to an infant one month old, doubling the dose with each month so that a child six months old should receive one and a half drams (6.00) of the preparation. He administers it mixed with one or two ounces of flaxseed tea. He states, in the treatment of infantile convulsions, that positive results are obtained within a few minutes.

In pertussis he obtained good results by administering it night and morning, diminishing the frequency and severity of the attacks. Also convulsions due to tuberculous meningitis were controlled by this preparation given three or four times in the twenty-four hours. Good results have been obtained from the use of this preparation in rachitis and epilepsy.

Hönigschmied, in *Pediatrics,* recommends bromipin in all affections where bromin preparations are indicated. He uses it in the treatment of vertigo, cerebrospinal meningitis, nervous insomnia, recent cases of chorea, in nightmare, melancholia and neuralgia. In cerebrospinal meningitis, he empties the bowel

and gives an enema of 1 to 4 drams (4.-15), according to the age. The bromipin is given alone slightly warmed. He cites several cases where bromipin was used successfully.

Laryngeal Tuberculosis.

Castex, in *Amer. Med.*, recommends in the treatment of laryngeal tuberculosis that hot flannel binders be applied to the neck and renewed frequently during the first stage of the disease. The laryngeal mucous membrane may be sprayed with one of the following solutions:

℞.	Sodii benzoatis	gr. xlv	3
	Aquæ destil.	ʒiii	90
M.	Sig.: As a spray; or:		
℞.	Acidi carbol.	gr. xv	1
	Glycerini		
	Aq. destil., āā	ʒii	60
M.	Sig.: As a spray; or:		
℞.	Menthol	gr. xv	1
	Gomenol	3iiss	10
	Alcoholis	ʒii	60
	Aq. destil.	ʒv	150
M.	Sig.: Apply locally as a spray.		

[Gomenol is a terpinol preparation.]

He recommends that the treatment of the larynx be repeated two or three times a day. In the third stage the following is recommended:

℞.	Cocainæ hydrochlor.	gr. xxx	2
	Morphinæ hydrochlor.	gr. xv	1
	Antipyrini	3iiss	10
	Glycerini (neutral)	ʒii	60
M.	Sig.: One teaspoonful added to half a glass of distilled water and used as a gargle.		

Solis-Cohen recommends the following combination:

℞.	Orthoform		
	Anesthesin, āā	3i	4
	Ext. suprenalis		
	Iodoformi, āā	3ii	8
M.	To be insufflated into the larynx, especially when painful ulcerations are present.		

And topically he advises the following:

℞.	Guaiacol	3iiss	10
	Menthol	3i	4
	Olei olivæ	3vi	25
M.	Sig.: Apply locally after an application of cocain.		

Vomiting in Tuberculosis.

Pegurier of Nice, in *Bul. gen. de Ther.*, states, in the treatment of vomiting of phthisis, that the excitability of the gastric mucosa must be calmed. Small pieces of ice after meals are of benefit, together with the administration of anesthetic substances such as aqua chloroformi, menthol, hydrogen peroxid, and iced champagne. The following may be given:

℞.	Aq. chloroformi		
	Syr. aurantii flores., āā	ʒii	60
M.	Sig.: One tablespoonful after each meal.		

The irritation causing the gastric irritability, such as tuberculosis of the pharynx, larynx or epiglottis, must be properly treated. As palliative measures the following combinations are recommended:

℞.	Pot. bromidi	3i	4
	Glycerini	ʒi	30
M.	Sig.: Paint the pharynx before each meal; or:		
℞.	Cocainæ hydrochlor	gr. xxiv	1|65
	Aquæ	ʒiii	90
M.	Sig.: Paint the pharynx when nausea appears; or:		
℞.	Diiodoformi	3ii	8
	Cocainæ hydrochlor.	gr. i	|06
	Morph. hydrochlor.	gr. 3/4	|05
M.	Sig.: To be used as an insufflation when the larynx is involved.		

Administration of Gelatin.

According to Racchi in the *Practitioner*, gelatin when administered in a normal serum solution is absorbed more rapidly when given in the form of an enema than by the hypodermic method. It is absorbed and shows its beneficial effect within five or ten minutes and continues for five or six hours.

Sodium Chlorid in Scrofula.

Liegois, according to an abstract in the *Monthly Cyc. of Pract. Med.*, states, in those conditions recognized under the term scrofula, that the chlorid of sodium enhances the appetite and increases the flow of salivary, gastric, biliary and pancreatic secretions and aids assimilation. The combustion of albuminoids is especially increased. This salt opposes the loss of phosphates and influences and assists endosmosis and exosmosis. There is marked effect on the blood also. The erythrocytes are increased and the hemoglobin percentage is higher. The following combination is recommended:

℞.	Sodii chloridi	gr. iss	|09
	Calcii phosphatis	gr. iii	|20
	Calcii carb.	gr. 1/6	|01
M.	Ft. chart. No. i. Sig.: One such powder four times a day after meals.		

The Use of Alkalies for Relieving Pain.

According to an abstract in the Pract. Med. Series of Year Books, Sir Lauder Brunton calls attention to the use of alkalies in relieving pain, especially that caused by toothache. The presence of acid in the carious tooth is the cause of the pain, and it has been demonstrated how the pain disappeared by the application of sodium bicarbonate. It is also of value in general aching of the teeth due to retracted gums. Alkalies relieve the sharp stinging pain accompanying furuncles, the pain in such cases being due to diminished alkalinity of the blood of the system in general as well as locally. Consequently he advocates alkalies both internally and locally in some cases of neuralgic and painful affections.

Pruritus.

Brocq, in *N. Y. and Phil. Med. Jour.*, gives the following combinations as of value in the treatment of pruritus:

℞.	Resorcin	gr. iv	|25
	Hydrarg. chloridi mitis	gr. xii	|75
	Zinci oxidi	gr. xxx	2
	Petrolati	3v	20
M.	Ft. unguentum. Sig.: Apply locally; or:		
℞.	Menthol	gr. iii	|20
	Acidi carbol.	gr. iv	|25
	Acidi salicylici	3ss	2
	Zinci oxidi	3iss	6
	Liq. petrolati	ʒi	30
M.	Ft. unguentum. Sig.: Apply locally to the affected parts.		

In pruritus of the vulva, Verchére, in the same periodical, recommends the following:

℞.	Hydrarg. bichloridi	gr. xv	1
	Alcoholis	3i	4
	Aq. rosæ	3v	20
	Aq. destil.	ʒvii	210
M.	Ft. lotio. Sig.: Apply locally twice a day.		

A. Robin advises the following to relieve the foregoing condition:

℞.	Spts. chloroformi	3ii	8
	Olei amygdalæ dulcis	ʒii	60
M.	Sig.: Apply locally; or:		
℞.	Hydrarg. bichloridi		
	Ammon. chloridi, āā	gr. ii	|12
	Emuls. amygdalæ	ʒvi	180
M.	Sig.: As a local application; or:		
℞.	Orthoformi		
	Diiodoformi		
	Talci, āā	3ii	8
M.	Ft. pulvis. Sig.: Apply locally; or:		
℞.	Menthol	gr. ¾	|05
	Guaiacol	gr. viiss	|50
	Zinci oxidi	3iiss	10
	Liq. petrolati	ʒi	30
M.	Ft. unguentum. Sig.: Apply locally.		

To relieve the pruritus arising from eczema of the ear, Lichtenstein recommends ointments in preference to lotions.

He employs, in addition to Lassar's paste, the following combinations:

℞. Olei cadini 3ss 2
Liq. petrolati 3v 20
M. Ft. unguentum. Sig.: Apply locally; or:

℞. Hydrarg. oxidi flavi .....gr. xv 1
Liq. petrolati 3iv 15
M. Ft. unguentum. Sig.: Apply locally.

According to Hyde, carbolic acid ranks first as an antipruritic, used in strength of 1 to 5 per cent. It may be combined as follows, according to Bronson, who uses it in a strong solution:

℞. Acidi carbol. 3i-ii 4.-8
Liq. potas. 3i 4
Olei lini .....℥i 30
M. Sig.: Apply locally only over small areas.

Hyde recommends the following as a valuable lotion to relieve the pruritus of eczema:

℞. Acidi carbol. .....gr. xl 2
Zinci oxidi 3i 4
Glycerini 3ii 8
Aq. calcis q. s. ad.....℥viii 240 65
M. Sig.: Apply locally.

Or one of the following combinations:

℞. Acidi hydrocyanici dil. 3ss-ii 2.-8
Zinci oxidi
Calamini, āā 3i 4
Aq. calcis
Aq. sambuci, āā .....℥iv 120
M. Sig.: Apply locally; or:

℞. Acidi carbol. 3ss-3ii 2.-8
Bismuthi subnit. 3i 4
Pulv. tragacanth. .....gr. xl 2
Aq. calcis .....℥viii 240 65
M. Sig.: To be applied locally; or:

℞. Acidi carbol. .....3iss-℥ss 6.-15
Glycerini 3ii 8
Menthol .....3i-℥ss 4.-15
Spts. vini rect. q. s.
Aq. destil. q. s. ad .....℥viii 240
M. Ft. lotio. Sig.: Apply locally.

Trigeminal Neuralgia.

Graham Brown, according to the *Courier of Med.*, recommends quinin in the treatment of neuralgia of the fifth nerve, given in two or three doses of ten grains each. Sodium salicylate may be given, but it is not so active as quinin. The following combination is also recommended as even more serviceable:

℞. Quininæ sulph.
Sodii salicylatis
Antipyrini, āā .....gr. v 30
M. Ft. chart. No. i. Sig.: One such powder every three or four hours.

He also advises aspirin in doses of grains 5 to 15 (.30-1.00). Butylchloral hydrate is very useful in such conditions combined with glycerin. Morphin should be resorted to only after all other remedies have failed.

Medicolegal.

Duty of Carrier When Passenger Becomes Sick.—The Supreme Court of Kansas holds, in Atchison, Topeka & Santa Fe Railway Company vs. Parry, that it is the duty of a carrier of passengers to exercise reasonable and ordinary care in looking after and protecting one who becomes sick or unconscious while a passenger. Whether such care has been exercised is ordinarily a question of fact for the jury.

No Action Maintainable by Posthumous Child.—The Supreme Court of California holds, in the case of Daubert vs. Western Meat Company, an action brought to recover damages for a man's death, that, where a child is unborn and its existence unknown to the party sued in such a case at the time a judgment in favor of the widow or other heirs is given, an action can not be maintained by the child after its birth, notwithstanding the provisions of section 29 of the Civil Code, to the effect that an unborn child is deemed to be in existence so far as necessary for its interests in the event of its subsequent birth. Whether the same rule would apply in a case where the existence of an unborn child was known to the party sued, at the time of the previous action and trial, the court says it was not intended to be here decided.

Communication to Undischarged Superseded Physician.—The Supreme Court of Kansas says, in the case of E. Patterson & Son vs. Cole, that a physician was employed to attend a patient who had suffered a personal injury. Afterwards the family physician came, and practically took charge of the case. Later, and within a few hours, the physician first called and again visited the patient, to inquire as to his condition, but administered no treatment. On this visit a statement was made to him by the patient as to the cause of the injury. The physician stated that he did not then regard himself as an attending physician, but admitted that there had been no discharge. The patient, on the other hand, stated that he regarded the doctor as his physician when the statement was said to have been made. The Supreme Court holds that, that being true, the relation of confidence existed, and the statement was rightly excluded on the ground that it was privileged.

Death from Medicine Taken to Allay Pain.—In the case before the Supreme Court of Missouri of Dezell vs. Fidelity and Casualty Company there was involved a policy of accident insurance which insured "against bodily injuries sustained through external, violent and accidental means," and which provided that "this insurance does not cover . . . injuries, fatal or otherwise, resulting from poison or anything accidentally or otherwise taken, administered, absorbed or inhaled." The court holds that the better reason supports the rule that such exceptions in such policies do not cover medicine (even though it contain poison) or anything taken or administered in good faith to alleviate physical pain, even though it results in unexpected and unintentional death. In this case, the death of the insured was caused by the effects of morphin contained in a prescription for neuralgia given him by his physician which he had had refilled, and the court holds that, so far as the provisions of the policy quoted were concerned, the beneficiary who brought this action was entitled to a verdict as a matter of law.

Skill Required of Surgeon—Not Insurer of Patients.—In the malpractice case of English vs. Free, according to the statement of the Supreme Court of Pennsylvania, the party suing had a car body fall on him, crushing him to the ground and seriously if not permanently injuring the hip joint. He was taken to the office of the party sued, a practicing surgeon, who examined the injury, gave morphia and had him sent to his home. The surgeon continued to treat the case for about four months. Two other surgeons during that time were also called in to see the patient. At the end of that time the surgeon sued told the patient he could do nothing more for him and ceased his attentions. As his hip was not well, and the leg shorter than the other, the man went to Pittsburg and entered a hospital, where the injury was diagnosed as a dislocation of the hip joint, and treated as such, the patient in about two weeks recovering and returning to his home. He claimed, however, and offered evidence tending to show, that there had not been a complete restoration of the limb to its normal condition, and that this result was owing to an incorrect diagnosis of his injury by the surgeon sued, and who, as he alleged, did not treat it as a dislocation, which it subsequently proved to be. The Supreme Court holds that a nonsuit was rightly entered. It says that it is settled law in this class of cases that "a surgeon undertakes to possess, and in the treatment of a case to employ, such reasonable skill and diligence as is ordinarily exercised in his profession; and in judging of the degree of skill, regard is to be had to the advanced state of the profession at the time." Taking this to be the law, the burden was on the party suing to prove, at least by the weight of the evidence, that the surgeon sued failed to treat him with reason-

able professional skill. The court thinks that he failed in this proof. It says that the surgeon beyond question was a skilled one, in good repute; he gave attention to the case; he called in to aid him two competent surgeons. It might be that he was mistaken in his diagnosis. The undisputed testimony of quite a number of surgeons, called as witnesses, was that this injury was such that it was very difficult to detect its exact character. The hospital surgeon, who, after putting the patient under the influence of an anesthetic, correctly diagnosed the injury as a dislocation, then reduced it, then by careful treatment practically cured him, testified that in the early stages of the injury it was sometimes exceedingly difficult, and almost impossible, to detect the exact character of the injury; that he had known such injuries to be only correctly diagnosed by the use of *x*-rays. And such was substantially the testimony of all the reputable surgeons called on either side. Taking the testimony of the party suing in its most favorable aspect, it only showed, not that the surgeon did not bring to the treatment of the case reasonable skill and diligence, but that he might have been mistaken in not finding out its exact nature. To hold him answerable for not exercising more than ordinary professional skill would be imposing on him a burden heavier than the law has yet put on the professional man's shoulders. A surgeon is not an insurer of his patients.

1. **The X-Rays.**—Williams finds the *x*-ray the very best method of treatment of numerous skin disorders, such as eczema, psoriasis, acne, sycosis, lupus, etc. In Hodgkin's disease, which has heretofore been hopeless as regards treatment, it seems to promise good results. Tuberculosis of the lung is still in the experimental stage, but good results have been reported and also in chronic tuberculous peritonitis. He also mentions conjunctivitis of long standing as yielding to these rays, and he remarks on their analgesic and tonic effects. As regards tumors, he thinks the rays promise the best modification of treatment for superficial new growths. As regards the deeper ones, great care must be taken in the selection of cases to avoid injuries and obtain good results. The dangers of *x*-ray injuries are mentioned, and he notes as a remarkable property of the rays their power of passing through healthy tissue without damaging it to bring about healing in unsound tissue beyond. The paper is illustrated with cases showing good results.

2. **Migraine.**—Rachford's theory of migraine is that it is an auto-intoxication, a constitutional trouble principally due to hepatic insufficiency causing a non-destruction of toxins which would otherwise be destroyed by the liver. He gives formulas for treatment. The following is the one which is principally recommended:

℞.	Sodii sulphatis (dry) .....gr. xxx	2	
	Sodii salicylatis (from wintergreen). gr. x		65
	Magnesi sulphatis .....gr. l	3	25
	Lithii benzoatis .....gr. v		33
	Tinct. nucis vomicæ .....gtt. iii		2
	Aquæ destil. to make .....℥iv	120	

M.

Modifications of this are also given. The formulas are analyzed. Magnesium sulphate is necessary to overcome the constipation and unload the portal circulation. Sodium sulphate acts much the same way. Nux vomica is largely to overcome the soapy taste, but sodium salicylate is the remedy *par excellence*, acting not only as an intestinal antiseptic, but as a stimulus to the function of the liver. This formula is made up in large quantities and put up in siphons charged with carbonic acid and sold on prescription at 50 or 60 cents. The adult patient is directed to take from one-fourth to one-half glass of this mixture each morning half an hour before breakfast, the only dose during the day. Other remedies mentioned are sodium benzoate in 20-gr. doses after lunch and dinner; sodium salicylate, salol or cannabis indica in ¼-gr. doses two or three times a day for the paroxysms. Another drug which has had a deservedly good reputation is mercury, and he has used it to great advantage in the form of gray powder in the treatment of migrainous conditions in children. For the attack itself he advises rest in bed in a dark room without food. If the attacks are very severe, citrate of caffein, 2 gr., and antipyrin, 10 gr., with 30 gr. of bromid of potassium in half a glass of water, sometimes substituting sodium salicylate for the antipyrin, and proper dieting. Hygienic treatment is essential. The patient should not be allowed to eat too much. Coffee, alcohol, sweets and red meats should be limited or eliminated from the diet. Exercise in the open air, etc., and general massage are advised.

3. **Paroxysmal Hematuria.**—This disorder is defined by Thompson as a profound neurosis, chiefly affecting the vasomotor system and called into activity by exposure to moderate degrees of cold, by muscular fatigue or mental emotion. He reports cases and discusses the theories of the disorder. The treatment is mainly satisfactory in the syphilitic forms, but patients who have to expose themselves to cold may do well to avoid mental and bodily fatigue and be warmly clad. Stimulants should be prohibited. Medicines, as a rule, are not of much value. The attacks may be aborted by hot baths or putting to bed with hot-water bottles or blankets, by taking simple hot draughts or hot milk. Diffusible stimulants are useful.

13 Holiday Repair vs. Climacteric Decay. John Knott.

7. **Intestinal Anastomosis.**—McGraw reviews the conditions that call for operation in the intestine or at the pylorus and notices certain peculiarities. He points out the symptoms which characterize pyloric obstruction or obstruction in the upper portion of the duodenum, mainly indigestion, eructation, distended and prolapsed stomach, increase of pain, vomiting consisting of mucus and blood as well as ingesta, absence of bile and swelling at the left of the median line as a rule. These may be simulated by the nausea of pregnancy or nervous nausea, but never by chronic dyspepsia. There should be no indecision when this train of symptoms appears, but surgery should be called in. He thinks that operation will usually be successful in pyloric obstruction so long as the ejecta consist solely of fluid and colorless mucus, but when the vomiting becomes green, or especially black, he refuses to operate. The question of the method is discussed. He points out the advantages which he claims for his elastic ligature. Its application is very simple. The two viscera are brought together and the surgeon connects them with a single line of Lembert sutures, a little longer than the desired opening. The rubber cord is then, by means of a large needle, passed through the walls of first one and then of the other bowel and tied firmly in a single knot. Before tying it, however, a silk thread is laid under the knot, and after the knot has been firmly tied with the rubber stretched to its utmost, the silk thread is

made to fasten it in place. Both threads are then cut short and the Lembert suture is now completed so as to form a ring enclosing the rubber. In passing the rubber through the gut it should be stretched in order to lessen the size and drawn slowly and carefully through in order not to tear the gut. Of course, the rubber must be fresh and first-class, as old rubber may break. The advantages of the procedure are its simplicity and rapidity, its aseptic quality, for the rubber fills the openings through which its passes, preventing extravasation; delay in opening the passage until the intestines have become well glued together, and the ability to make with it a communication of any desired length. If we compare it with the incision and suture it is much more easily and quickly performed, much more aseptic; it causes less hemorrhage and is less liable to dangerous complications from faulty technic than the Murphy button. The disadvantages which have prevented its more general use are the fact that the surgeon can not see the opening that he makes. He closes the abdomen on still intact intestines and is obliged to put his trust in the slow, unseen action of a constantly contracting rubber cord, but it is only after repeated trials of its efficiency that he learns to have confidence in the procedure.

8.—See abstract in THE JOURNAL of September 5, p. 626.

10. **Hypertrophy of the Pharyngeal Tonsil.**—The conditions accompanying overgrowth of the pharyngeal tonsil, which Wood declares is a distinct organ, are described in detail by him. He says the tonsils are of no more importance than the ordinary lymph gland, and their removal, therefore, offers no objection. He divides the complications of hypertrophy of the pharyngeal tonsil into two groups: mechanical and infectious. Mouth breathing is almost purely a mechanical complication, but may produce conditions favoring infection. He thinks that many children who appear backward at school are so because of aprosexia, as it has been called, or failure of attention connected with this condition of adenoids. Skeletal deformities, such as chicken breast, narrowing of the alveolar arch of the upper jaw, etc., are frequently due to mouth breathing, though the latter is due more to poor nourishment than to any mechanical influences. The most serious complications due to hypertrophy of the pharyngeal tonsil are otitic disturbances. While involution of the tonsil usually takes place between the ages of 10 and 20, he has seen the pharyngeal tonsil well developed in persons of 40. He closes with the statistics of the dispensary records of the Children's Hospital with a total of 361 patients with nose and throat trouble. Of these 149 were hypertrophy or adenoid growths; 87 of these being boys and 62 girls. Nasal discharge or recurrent attacks of coryza were present in 78 cases; some form of ear trouble was present in 63, or 42 per cent. Symptoms of nasal obstruction were present in 117, or 78 per cent. Headache was present in 28 cases, 19 per cent.; cough in 45 cases, or 30 per cent. All these symptoms depend on the adenoid hypertrophy and disappear after removal of the growth. When a number of such symptoms are present he believes a tentative diagnosis can be made in the majority of cases.

11. **Surgery of the Upper Right Quadrant of the Abdomen.**—Binnie draws attention to the easily neglected fact that biliary lithiasis and empyema of the gall bladder are not the only affections of the right upper quadrant of the abdomen which are open to surgical relief.

18 *An Operation for Removing the Tonsils. William H. Steers.

14.—See abstract in THE JOURNAL, xl, p. 1670.

15. **Manic Depressive Psychoses.**—Berry describes this condition as understood by alienists and reports a case. He calls attention to the danger of consanguineous marriages and of heredity in these cases.

17. **Anesthetics in Children.**—Kopetzky says that the claim that the use of chloroform is safer than the employment of ether with children is not borne out by close observation. This is especially true in robust and healthy children. It is dangerous because an overdose may be easily given. Cardiac failure may set in at the beginning of the administration because of the violent and dangerous struggles which take place, and the tendency to push the anesthetic is too tempting. Cardiac syncope following vomiting may occur at any time during the administration of chloroform, or after, and result fatally. On the other hand, nitrous oxid is quick in action, without dangerous symptoms, and when followed by ether from a closed inhaler, rapid evaporation from the lung is avoided and ether pneumonia does not occur. In conclusion he warns against the practice of commencing short operations on the nose and throat and eye before complete anesthesia has been induced; also the practice of using chloroform in the upright position.

18. **Tonsillotomy.**—Steers recommends the use of a hook-like knife modeled from a strabismus hook, with a longer and stouter handle and with a knife edge on the concavity and the end of the hook. The finger of the operator is passed over and around the tonsils to detect any pulsating vessels and the lower tonsil is seized with a volsellum and drawn toward the opposite side. The described hook-knife is then passed between the tonsil and the anterior pillar of the fauces, just beneath what he terms the basement membrane of the tonsil, care being taken that it is not passed into the tonsil mass, but beneath its basement membrane. The finger of the operator is then introduced into the wound, and making sure that pulsating vessels can not be felt, and using the finger as a blunt dissector, the mass is turned out, thus leaving it attached only to the posterior pillar and by mucous membrane only, which is divided by an ordinary blunt-pointed tonsil bistoury. Hemorrhage is free at first, but ceases promptly. If any bleeding vessels are present they are seized with forceps and treated as in any other situation. When removed it will be found that the base of the tonsil is covered by a thin membrane and that the dissection has been carried on entirely outside the tonsil. Without turning the patient the other tonsil is then removed in the same way. After the wounds have healed it will be found that the pillars of the fauces stand out in their proper position and their muscles act freely. There will be no return of the tumor. He thinks we may guard against most hemorrhages by careful palpation and dissection outside the tonsillar tissues and by completely removing the growth.

22 *A Form of Rational Treatment for Corneal Ulcers. William L. Phillips.
23 Growths of the Male Urethra, with Report of Three Cases. Joseph E. Morrow.

19. **Fractures.**—McConnell condemns the ready-made splint and pleads for immobilization of fractures, the use of absorbent cotton and the making and adjusting of plaster-of-paris strips. Ordinary plaster-of-paris bandages he considers a relic of barbarism. In retaining fractures in children, especially of the lower end of the humerus involving the joint and of all fractures or displacements above or below the joint, he uses absorbent cotton. He cuts out absorbent cotton strips, folding them over to get the desired length and thickness, and with two bands of this kind puts the limb in the desired position and adapts them as he would ordinary splints. He first employed this method by accident, but has since used it in fifteen cases altogether, greatly to his satisfaction. In putting up fractures of the lower end of the humerus he objects to the method of flexion and thinks extension is much better, as it has the advantage of enabling one to examine the dressings with a minimum of distress to the patient. In the treatment of fractures of the leg he uses for a permanent dressing splints

of cotton flannel, the lateral ones overlapping the more posterior one, and also the foot, holding it at right angle to the limb, covered and stiffened with plaster of paris, to be applied after temporary dressing with the long wood splints, the posterior one being retained with the permanent dressing. The advantages of these overlapping splints made in this way with the spine of the tibia exposed is that it makes a light, firm, close-fitting dressing; the absence of cotton wadding permits the splint to mold itself, and the use of one layer of wide gauze bandage makes it impossible to constrict the member; the spine of the tibia being exposed any deviation in alignment is readily detected. Lateral inspection is facilitated by cutting the bandage between the side splints, lowering one or both, and again tightening them with straps. At any time, grasping the two side splints between the two hands any looseness will be discovered. This form of dressing immobilizes the knee, ankle joint and fractured bones and maintains the foot at a right angle. If proper care and skill have been used in the application, it will be unnecessary to remove the posterior splint until union has occurred, and last, but not least, the patient can lie on his side, sit up, or place the limb in any position he desires. McConnell criticises the use of passive motion in fractures in or near the joint at any time until after the fourth week. In conclusion he says our objects in the treatment of fracture should be: 1. Restoration of function. 2. Maintenance of the symmetry of the member. These should be accomplished by procedures that are as comfortable to the patient and as little annoying to the surgeon as is consistent with the object desired.

20. **Tuberculosis.**—Cobb reviews the various theories of infection in tuberculosis, showing that foreign matter can be inhaled directly into the lungs and that it may also reach the lungs through the intestinal tract. In cattle he holds infection is caused by ingestion of infected sputum in the case of the cow, of tuberculous milk and offal in swine, and in birds and fowls by picking in their own infected dejecta. In man, while he admits the inhalation possibilities, he thinks the principal avenue of infection is through the ingesta. Milk he does not consider an important factor, basing his opinion largely on the great frequency of tuberculosis among the Chinese and other people that do not use milk to any extent. His personal opinion is that tuberculosis can be conveyed both by inhalation and ingestion, but largely, if not principally, by infected food, the common house fly being the medium of conveyance from the ejected sputum to the food on which it alights.

22. **Corneal Ulcer.**—The rational treatment here described by Phillips consists in the use of adrenalin to contract the arteries, mild antiseptics, like boric acid, to antisepticize the conjunctival sac, nuclein solution, 5 per cent. (the hypodermic solution being less irritating), to build up the lymph corpuscles to a healthy condition; lastly, he would treat the conditions that have a bearing on the disease. In many cases the ulcer originates from other diseased parts, such as caries, adenoids, hypertrophies of the turbinates, etc. He would drop the suprarenal extract into the eye three times a day, and if the severity of the disease increases, the medicine must be instilled oftener, depending on the absorption of the drug and its action on the heart. The eye should be kept clean with warm boric acid solution, the nuclein solution being combined with and given in the same way as the suprarenal. Adrenalin chlorid 1-1000 does not seem to produce the same effect as does the suprarenal and chloretone when combined with the nuclein solution.

24 *Urethral Tuberculosis, with Report of a Case. Arthur L. Chute.
25 *A Note on the Transmission of Whooping Cough by Indirect Contagion. John Lovett Morse.
26 The Ill Health of Francis Parkman. (Concluded.) George M. Gould.

24. **Urethral Tuberculosis.**—After detailing a case Chute discusses the literature and the characteristics of the disorder. In the cases which have come to autopsy he finds there have been almost invariably other lesions of the genito-urinary tract, and tuberculosis of the urethra may have been secondary to them. Lesions of the prostate, epididymis and vesicles are almost always associated with infection by extension. The question whether urethral tuberculosis may be primary is still an open one, but in most cases it is unquestionably secondary. The symptoms, aside from hematuria, are gleety discharge, pain on urination, nodular conditions and obstruction. The painful erections from which his patient suffered seem to have been unusual. Tubercle bacilli in the discharge is indisputable proof. Granulations or multiple ulcers of the urethra are almost pathognomonic. A urethral discharge with no history of exposure to venereal infection is suggestive, especially if no gonococci can be found. The prognosis depends largely on the primary disease. Most of the reported cases have been fatal and recovery will necessarily be tedious. The treatment will depend on the primary disorder. Hygienic measures usually hold a most important place. Chute is doubtful as to the local treatment. Where a stricture or infiltration offers an obstruction, of course surgical measures are required, and also where there is spongiosum involvement with cavities the tuberculous cavities should be laid open, or where the urethra is greatly ulcerated, perineal urethrostomy may give relief and may bring about recovery. In some very advanced cases amputation is the best procedure.

25. **Whooping Cough.**—Morse has been repeatedly asked whether whooping cough could be carried by a third party, and he wrote a circular letter to the members of the American Pediatric Association and received replies from forty. Three of them reported 5 cases, one of which seemed rather doubtful. Opinions vary as to its possibility. He thinks it hardly possible to draw positive conclusions. The cases which were given seemed to justify the assumption that whooping cough can be carried by a third person, but the fact that forty members of so wide experience see so few cases proves that it must be very rare.

33. **Granular Degeneration of the Red Corpuscles.**—This phenomenon, which has been attributed to degenerative processes, is held by Fisch to be rather a regenerative one. It is normal in the fetus and also in certain animals. It disappears in anemic cases before death; if it were retrogressive he could not explain why it should be limited before death. He cites other reasons which confirm his opinion as to its non-degenerative character. He thinks the granulations have a nuclear origin.

37 *The Choice of a General Anesthetic in Ophthalmology. Edward Jackson.
38 Eye Strain and Functional Disorders. Charles A. Wishart.
39 Ear Diseases in General Practice. I. P. Klingensmith.

35. **Intestinal Peristalsis in Diagnosis.**—Gaub has studied experimentally and otherwise the diagnostic value of intestinal peristalsis as a sign of intestinal injury in cases of non-penetrating abdominal injuries. He operated on dogs and concludes that if any lesion of the gastro-intestinal tract occurs the peristalsis usually returns with general subsidence of the

symptoms of shock. Often the absence of peristaltic movement, he concludes, is not of sufficient value to determine the celiotomy, and the increase of the pulse rate, 120 or over, if peristalsis is present, does not justify opening the abdomen. If an accumulating exudate is found by palpation and percussion, operation is necessary. If all means to prevent shock have been exhausted and the pulse rate is small and rapid and peristaltic movement absent at the end of four hours, exploratory operation is justifiable. The facial expression and the presence of rigidity and tenderness may often be sufficient to induce operation at a still earlier date.

37. **The Anesthetic in Eye Operations.**—Jackson finds that nitrous oxid anesthesia is too brief for some cases and not entirely without danger, but the principal objection to it is the intense venous congestion it causes. While ether is unquestionably less dangerous than chloroform, its irritating qualities are to some extent against it. Chloroform is objectionable on account of the danger of cardiac inhibition, and if operations about the face are specially prone to cause such accidents, those about the orbit can be no exception. He speaks favorably of ethyl bromid, but it must be used with all the precautions observed in the administration of chloroform. Rapidity of recovery may be a drawback if the administration is not closely watched. It certainly is unsuited for use in cases of prolonged operation. General anesthesia may be required if the eye is severely inflamed. Nitrous oxid and bromid of ethyl are hardly to be considered in these cases. For enucleation of the eyeball, or the extirpation of tumors within the orbit, the greater safety of ether will generally decide in its favor, but venous congestion is against it in the difficult dissections deep in the orbit. Where the actual cautery is required ether is contraindicated on account of its inflammability. Ethyl bromid is not satisfactory for the destruction of embedded powder grains, because the anesthesia is liable to be incomplete, but it is especially appropriate for strabismus operations in young children. He would not allow it to be employed except when administered by an experienced person drop by drop, as in the case of chloroform.

43 A Rational, Rapid and Efficient Remedy for Gonorrhea. W. H. Whitehead.
44 Some Facts in Regard to the Use of Strychnin. A. L. Benedict.

41. **Clay Paste.**—Wallis finds a mixture of wet sterilized clay for application in skin diseases has decided advantages. It has, beside its property of holding water and thus assisting osmosis, some therapeutic virtues depending on the mineral salts present, not overlooking the antiseptic, alterative, astringent and sedative properties peculiar to certain of the absorbent earths. Clays containing a large percentage of kaolin are preferred, and the dressing kept constantly moist by the application of a wet towel several times a day. To further prevent its becoming dry, he modifies his preparation by adding vaselin or lard, incorporating the fat with the paste by the aid of an emulsifying agent, the best of which is ichthyol. His standard paste contains 50 parts of kaolin and 25 each of water and petrolatum, with 4 per cent. ichthyol. Of course, the formula can be modified. In eczema rubrum of the leg, this formula may require a larger amount of kaolin and a diminished amount of vaselin. He thinks care should be taken to avoid an excess of ichthyol, which is irritating in certain forms of eczema. Glycerin should be used in this combination with caution, as it may cause discomfort and increased inflammation.

50 Two Cases of Tetanus Which Recovered. J. C. Boehm.
51 Immobilization of the Lower Jaw. John T. Rogers.

45. **Tuberculosis.**—Johnston points out that the so-called incipient and curable cases of tuberculosis are, for the most part at least, those of the so-called pretubercular condition, and that when the disease is fairly advanced in the great majority of cases there is little hope of its cure. There are certain cases where signs of tuberculosis exist, and yet the disease is absent, such as those with bronchiectasis, the result of a former bronchitis, and exceptionally in case of consolidated lung tissue after pneumonia. Old cicatricial tubercular lesions are present, he thinks, in quite a percentage of people after 30 years of age. When these patients are run down they usually cough a great deal and present symptoms of tuberculosis without actually having the disease. He thinks such cases swell the list of cures of consumption. In another class of cases the disease may be quite curable where the tendency to fibrosis is so strong that the infective process is kept within bounds. The main trouble, however, in the diagnosis of early consumption is the late recourse to treatment of the patients themselves. The diagnosis of pulmonary tuberculosis in its early stage, whether characterized by general weakness, loss of weight, chronic dyspepsia, etc., is a matter of weeks, and sometimes of months.

49. **Chronic Alcoholic Insanity.**—Dunning thinks the importance of recognition of alcoholic insanity is very great, but is often exceedingly difficult. The profession, therefore, should make a more careful study of the chronic alcoholic and be able to distinguish between the sane and insane alcoholic cases. The state should also be induced to provide for prolonged restraint and control of that class of periodic insanity known as dipsomania as well as other types of alcoholic insanity. When we are satisfied that a man is insane, he thinks, we should stand by our conviction regardless of lawyers or the popular notion that common drunkenness accounts for the erratic behavior.

53 *How Should a Modern City Protect Its Water Supply? Charles O'Donovan.
54 Suggestions Concerning the Prevention of Serious Complications in Ear Diseases. Hiram Woods.

53. **Protection of the Water Supply.**—O'Donovan recommends that cities should buy up large tracts of territory, including the water sheds from which their water supply is derived, and forest it, making it a sort of public park, a part of which might be used as a pasture, but cultivation should be excluded, and any land which is liable to produce silting into the streams from which the water is derived should be acquired and devoted to forests or pasture. In this way a double purpose will be served, a revenue would be at the same time acquired, the city would have a public park and the water supply would be purified.

69 *An Uncomplicated Fourth-Nerve Paralysis of Traumatic Origin. James W. Dunn.
70 *Will Certain Occupations in Time Affect the Cylindrical Curvature of the Eyeball? Paul Guilford.

69. **Uncomplicated Fourth Nerve Paralysis.**—In the case reported by Dunn the man fell, striking the back of his head. He soon apparently recovered, but the next morning diplopia was present in the lower field. The only other symptom was the contusion on the back of the head. The treatment given was iodid of potash and mercury internally and galvanism, soon changed to iodid alone and local applications of faradism. Improvement began in four weeks and remained stationary for about a month, when the double vision suddenly disappeared. Dunn thinks this precludes any possibility of fracture of the base of the skull, and that, as in the cases reported by Leber, the lesion was rupture of the trunk of the fourth nerve by concussion.

70. **Curvature of the Eyeball.**—Guilford finds that railroad engineers show very markedly greater flattening of the eyeball than do other persons of the same age, and attributes it to pressure of the wind. The engineer sits in his cab with head out, usually looking directly forward, and presses his eyelids close against the ball to protect the eyes from dust, etc., which tends to flatten the cornea. He says if this is true with locomotive engineers might it not be true perhaps to a lesser extent in others engaged in outdoor occupations exposed to the wind.

75 Excision of the Tongue for Cancer. Walter Whitehead.

71. **The "Ball-Valve" in Appendicitis.**—Van Zwalenburg describes the different anomalies in appendicitis and explains his theory as to the action of the loose bodies and the ball-valve in producing symptoms. He concludes as follows:

To sum up, my argument is: 1. That the ball-valve is an important factor in many cases of appendicitis, I am inclined to say the majority. 2. That in some cases, at least, the ball-valve is the principal factor and directly responsible for the acute attack. 3. That the pressure on the blood vessels of the mucosa and submucosa is the cause of the infection, and of the necrotic changes. 4. That a number of the symptoms of appendicitis are evidence of obstruction or strangulation. 5. That the first condition, being purely a mechanical one, practically a strangulation, the importance of immediate operation follows as a corollary. In conclusion, may I suggest that you distend a few appendices as I have indicated, and note the pressure effects, instead of splitting them all open immediately to see the concretion.

77 *Hemorrhage Into the Cranial Cavity Following Injury to the Skull. Charles H. Lemon.
78 Report of a Case of Tuberculosis of the Adrenals, with Pathologic Specimens. Julius Noer.

76. **Altitude in Neuralgia.**—Pearce reports two cases of facial neuralgia, one of which was badly affected by residence at a height of 2,500 feet above the sea level, the other by residence in Denver at an altitude of one mile above the sea level. Residence in a lower altitude decidedly benefited the condition. He suggests that there is quite a field for study as to the effect of climate and altitude on disease.

77. **Brain Hemorrhage.**—Lemon holds that all cases of brain congestion and laceration should be operated on, but as many cases give symptoms out of proportion to the actual injury, instead of waiting for classical symptoms to show themselves when signs of cerebral compression are present and the life of the patient is imperiled, the physician should select some plan for relieving the undue tension. The reasons for making a window in one of the long bones within the first forty-eight hours for osteomyelitis are no greater than those for making one in the skull for the same purpose of relieving tension. He thinks we should in future be more on the lookout for signs of compression and use the trephine and chisel more promptly to allow the products of inflammation to escape. Three cases illustrating his ideas are reported.

82 Does Lodge Doctoring Pay? Robert E. Coughlin.
83 Surgical Treatment of Congenital Clefts of the Palate in Infants. Truman W. Brophy.

79. **Lateral and Retropositions of the Uterus.**—The special subject of Ill's article is displacement and fixation caused by the short sacral and short broad ligaments, and not due to inflammation or adhesions, scars or tumors. The first writer who mentioned lateral displacement as producing symptoms was Schultz of Vienna, but since then Burrage of Boston has noticed the subject. Lateral displacements seem to be acquired during childhood or possibly are congenital. If the former is the case, the symptoms begin with the onset of menstrual life. The symptomatology is not very varied. There is usually pain in one or the other iliac region, most commonly on the side of the longer ligament, sometimes severe enough to prevent exercise, and it even has caused the recommendation of removal of the ovary. The pain increases at the menstrual epoch, and it usually takes the patient several days to recover. A sensitive spine or painful coccyx are occasionally observed, and these are commonly the most hopeless cases. In the case of short, sensitive uterosacral ligaments there is constant backache, located at the sacrum or lower lumbar region. In many of these cases occipital or vertex headache or both are present. With one uterosacral ligament short and sensitive, the pain is commonly referred to the sacroiliac synchondrosis of the short side. Most patients become more or less neurasthenic. The prognosis is bad if the case is of long duration. In the severer cases he has suggested thorough stretching of the short uterosacral or broad ligament under complete anesthesia. After stretching the ligaments until the uterus is freely movable he concludes by curetting and packing. The result is usually good. In one or two cases extirpation of the uterus has been suggested as a last resort for the relief of complete invalidism and the results have been good. Pregnancy may relieve the condition to some extent. It is most common in the unmarried and sterile married.

81. **Neurasthenia.**—MacCoy gives an account of the dispensary treatment of neurasthenia. He remarks that acquired neurasthenia seldom develops much before 25 years of age, and frequently not until long after that period. The neurotic instability of the hereditary is one of the most important factors. The physician must remember that there is a weakness of all the functions, mental, physical and moral, but there is always something to work on. Many cases improve greatly under simple medication and change in the habits of life. He remarks on the importance of a cheerful manner toward these patients and of psychic treatment generally. The treatment is quite as much psychic as pathologic, and he ascribes importance to positive assurances as to recovery and the insistence on certain directions. On the second visit the patients almost invariably report an improvement. Simple sedatives have done much for their sleep, the intestinal canal has been cleaned out and a regularity of life has become more or less established. The reason for their improvement is explained to them. When you have gained their confidence you can begin to make more complete the educational manage-

ment which has been begun so well. Sponge baths at bedtime of tepid water are valuable, as is also electricity, though it is not the important agent that the electric enthusiast would urge. He would forbid tea, coffee and alcohol as a rule, and substitute hot water, cocoa and milk. The patients should take only such food as agrees with them. Neurasthenic patients are very amenable to suggestion and the physician who fails to avail himself of this loses a large part of his medical armamentarium.

90 Omental Anastomosis or Operations for Establishing a Collateral Circulation of the Portal Blood; a Successful Schlassi Operation. J. P. Lord.
91 Thrombosis of the Lateral Sinus and Jugular Vein; Abscess of the Lung; Recovery. H. Gifford.

86. **Surgery of the Biliary Passages.**—The following points are emphasized by Davis:

1. A symptom-producing gall bladder so seldom ceases to give trouble without surgical treatment that an early operation before permanent crippling has been done is the safest. 2. In simple, uncomplicated cases of cholelithiasis or catarrhal cholecystitis, with practically a normal gall bladder, cholecystotomy with drainage until infection has disappeared is usually safe and most convenient. 3. Atrophied gall bladders with thick, friable and inelastic walls, those with destruction of more or less of the mucous membrane, and especially those where the cystic ducts are not free, should be removed, as this offers the best chance for complete cure. 4. Stone in the common duct should be removed by incision without suture of the duct. 5. In cases of temporary obstruction of the common duct, cholecystotomy is the safest method of relief until the obstruction disappears. 6. In permanent occlusion of the common duct the best results are obtained by anastomosing the gall bladder with the bowel. 7. The same line of treatment is applicable in all cases of cholecystitis and cholangeitis, whether or not complicated by gallstones.

87. **The Davison Ligature.**—The principal feature of this ligature is described as a simple reverse bowknot tied at each end of the wound, four or five inches from the end of the strand, allowing the ends of the strand to protrude from the angle of the wound, so that it can be untied and pulled out. It is recommended by Hamilton as a convenient and easily removable buried suture. Coarse silkworm gut is the material used, and the ligature offers good chances for certain sterility, accurate layer approximation of the tissue and the removal of buried sutures when healing is completed, capillary drainage from each layer, rapidity of the application, slight scarring of the skin, and all the advantages of permanent buried suture without the danger of further irritation and extrusion of the knot. It has also the advantages of an unabsorbable suture without the danger of sepsis, and without producing a nidus for septic germs from the blood current during absorption.

89. **Intestinal Anastomosis.**—Hepperlen uses a gelatin cylinder over which he sews the gut, inserting a few interrupted sutures through all the coats of the bowel to hold the parts, then using a suture of his own. He uses a fine intestinal silk twenty-four inches long, doubled, with a needle on each end, having the knot where the ends of the silk are tied in the center. He starts the first suture under the mesentery attachment, inserting a needle with each hand at the same time through the two outside coats of the bowel, an eighth of an inch from the cut margins, picking up a loop about one-twelfth of an inch in length, according to the method of Lambord, drawing the parts together and tying them at every stitch, continuing until he has completely encircled the bowel, closing the mesentery opening with the same suture, being careful to pass the needles under the small vessels in the peritoneal coat, so as not to unduly constrict the blood supply. He claims the advantages of simplicity, rapidity of work without handling the parts, firmness of union of the bowel ends. With the aid of the capsule and the suture recommended above, the end-to-end anastomosis may be performed in five to ten minutes.

1. **Leprosy.**—Hutchinson discredits the contagion of leprosy, claiming that experimental inoculation with one very dubious exception has always failed. It is infrequently transmitted from the husband to the wife. It is of widespread prevalence where it occurs, but nowhere common, and nothing like epidemic prevalence is ever observed and large sections of the population are almost wholly exempt. Attendants in leper hospitals never contract the disease. Lepers residing in England, France and America at the present day never become foci from which the disease spreads. When leprous communities are removed to a distance the disease dies out and when the social conditions are changed the same is true. He points out the arguments in favor of his fish theory, admitting that it is not the quantity but the quality that is responsible. He lays it to decayed or badly cured fish instead to the fish *per se*. Among the arguments he offers are that the fish hypothesis explains its antiquity, its widespread prevalence in local districts, and its excessive incidence in connection with the Roman Catholic religion; explains the dying out of the disease in connection with the advance of civilization and its persistence in certain localities where a large consumption of poorly cured fish exists, as also its great prevalence in the middle ages and its absence from mid-Russia. It also accounts for *de novo* and sporadic cases.

In the discussion which followed by Drs. Manson, Sambon, Cantlie, Hillis and others, the fish hypothesis was not generally favored.

3. **Lathyrism.**—This disorder, which is characterized by a paralysis of the lower limbs, with spasm of the thigh adductors and exaggeration of the reflexes without disturbance of sensation, bladder or rectum involvement or participation of the upper limbs of the trunk, is discussed by Hendley, especially as relating to its etiology. He comes to the conclusion that it is a form of intoxication not exclusively due to the diet of lathyrus, which only produces a predisposition to it. Its immediate exciting cause is exposure to cold, rain and damp weather. This explains the immense predominance of males affected with the disease and its occurrence in the rainy season when they are out and exposed in their work. It does not seem to be dangerous to life, but the paralysis is not curable. The spinal cord does not seem to be involved as a rule, though a softening above the lumbar enlargement has been found in one case by Scheube.

4. **Railroad Refreshments in the Tropics.**—The danger of taking meals at railroad stations, etc., the need of better latrine and lavatory service, especially in India, are emphasized by McCulloch, who gives instances of the evils which he says exist. Even the drinking water and every kind of refreshment is likely to be infected.

6. **Tropical Malaria.**—The methods of meeting tropical malaria, which is usually of the severe type, are discussed by Fernando, who finds that destroying the mosquito larvæ over sparsely populated districts is impracticable, and mosquito-proof houses on a large scale are also impossible for the natives, whose simple mud houses generally cost them practically nothing, and they can afford no better. He thinks in dealing with malaria in a district the following points should be insisted on:

1. A prompt search for cases of fever as fast as they occur with efficient treatment. If necessary, or otherwise practicable, malaria should be included in the list of infectious diseases whose notification to the local sanitary authority is compulsory. 2. The continued treatment of fever cases after the attack is over to prevent relapses. 3. The systematic treatment, especially during the non-fever season, of the cases of anemia and other forms of debility induced by chronic malarial poisoning. The above measures represent the least that can be expected from a sanitary authority in the treatment of malaria in an infected district, and it is gratifying to observe that when such measures are effectively carried out a great deal will have been done to exterminate the disease. The surest prophylaxis consists in efficient treatment.

7. **Plague in Domestic Animals.**—Cantlie points out the dangers of plague in the lower animals, which render the question of its prophylaxis a much broader one than has been heretofore considered. Not merely domestic animals may be infected, but marmots, bats, pigeons and probably many others are likewise susceptible.

33 *A Clinical Comparison of the Maternal Pelvis and of the Fetus in Europeans, Eurasians and Bengalis, and the Enunciation of a New Law, in Accordance with Which the Size of the Child at Birth Is Determined. Clayton Arbuthnot Lane.

26. **Typhoid Perforation.**—This condition, as here pointed out by Mackenzie, is much more frequent than is sometimes thought to be the case, occurring as it does in 3 or 4 per cent. of all cases and causing at least 25 per cent. of deaths. Mackenzie shows that it may occur even in the mildest cases, most frequently, however, in males, and that it is apparently most frequent about the third or between the second and fourth weeks. Its site is usually in the last twelve inches of the ileum, in which the ulceration is most severe. The symptoms are more or less characteristic. He discusses them at some length and concludes that every case of typhoid fever should be looked on as one of possible perforation for which the medical man should be prepared. He recommends a careful study of the schedule of instructions drawn up by Osler as to the duty of the nurse in watching the pulse, condition as to pain, condition of the abdomen, whether distended, flat or contracted, the presence or absence of respiratory movement, tenderness, rigidity of muscles, spasm, temperature, respiration, its frequency and character. If the physician suspects perforation he would do well to at once summon a surgeon, the one he has selected as operator, and to see that provision is made against shock, with sufficient hot water bottles, blankets, stimulants, etc., with suitable table and good light for operating and other means, especially in private houses. A number of cases are reported. The prognosis is certainly better than it used to be looked on, as large a proportion as one-third having been recorded as recovered in some statistics.

30. **Neuritis of the Arm.**—The cases reported by Warrington illustrate Erb and Duchenne's palsy of the upper part of the brachial plexus and Klumpke's palsy of the lower part, the uniradicular paralysis described by Buzzard where the lesion is limited to one of the nerves forming the brachial plexus; a case of monoplegia and one of localized multiple neuritis, a paralysis of the fifth peripheral nerve and a professional or occupation paralysis, which in some cases is due to actual neuritis, and others apparently the result of pressure or overuse.

33. **The Maternal Pelvis.**—Lane has studied the proportions of the maternal pelvis in the European, Eurasian and Bengalis, and formulates from the results of his studies the following law: "The child grows *in utero* in such a manner and at such a rate that at full term his size is proportional to that of the mother's pelvis through which he has to pass in order to be born." The weight of the child and its size at birth has a distinct relation to the pelvis, and the biparietal diameter of the child increases correspondingly with the conjugate diameter of the pelvis through which it will ordinarily pass at birth. The mechanism by which this law is maintained is, he thinks, that of ordinary natural selection.

37. **Cerebrospinal Fluid in Secondary Stage of Syphilis.**—Ravaut gives the particulars of 84 cases of secondary syphilis in which the cerebrospinal fluid was examined. They indicate that every intense and persisting cutaneous manifestation in syphilis generally coincides with a reaction on the part of the nervous system. In most of the patients there were no symptoms, except the findings in this fluid, to suggest the parallel involvement of the nervous system. In 34 cases with slight and transient cutaneous manifestations the cerebrospinal fluid was normal in all but 3, while in 36 with pigmented or papulous syphilides the fluid showed an evident reaction. Possibly a second examination might have shown that these exceptions, too, conformed to the rule. The findings in the cerebrospinal fluid paralleled the course of the cutaneous affection, but did not seem to bear any relation to the frequency or intensity of the headaches observed in some cases. He classes the findings as follows: marked reaction, with 20 to 150 leucocytes in the field; moderate, with 7 to 20; slight, with 4 to 6 leucocytes, and negative, with none, or at most 2 or 3 leucocytes to the field. They were exclusively lymphocytes. In 3 cases a few polynuclear cells could also be discovered and occasionally a few large mononuclears were found among the lymphocytes, but took the stain poorly. No red corpuscles were ever found. It is impossible to draw conclusions from the facts cited, but they demonstrate how promptly and how insidiously the nervous system is affected by the syphilitic virus. They also apparently confirm Brissaud's theory that the virus has a special affinity for the ectoderm, and suggest the necessity for energetic specific treatment, admitting that these reactions are a new symptom of syphilis in full activity, demanding immediate treatment.

38. **Cerebrospinal Fluid in Tabes.**—Milian has been studying the behavior of this fluid in tabes, and his findings in 20 cases show that stationary tabes with a tendency to latency has a normal cerebrospinal fluid, while there is slight lymphocytosis in those cases of tabes of slow progress, the syphilitic infection of remote date. Pronounced tabes with ataxia is accompanied by decided lymphocytosis, and likewise incipient tabes consecutive to recent infection. The lymphocytosis in tabes does not seem to be modified by mercurial treatment, contrary to what is observed in the lymphocytosis of hemiplegia from arteritis, which rapidly improves under treatment. This fact seems to support Fournier's assertions in regard to the parasyphilitic nature of tabes.

44. **Detection of Tubercle Bacilli by Inoscopy.**—Masselin corroborates Jousset's assertion that his inoscopy allows the detection of tubercle bacilli even very scantily present in the organic fluids. He reviews his extensive experience with it, and adds that if the results are negative he never dismisses the case as positively non-tuberculous until inoculation of guinea-pigs has also resulted negatively. In Behring's address below, inoscopy is also referred to as a notable progress. [The technic was given in The Journal, page 546, paragraph 46, of the last volume. It reveals the bacilli in organic fluids in which they have hitherto escaped detection. It is based on the fact that bacteria become entangled in the fibrin of organic fluids. By dissolving out the fibrin with a pepsin digesting mixture the bacilli are set free and can be obtained by centrifuging for examination under the microscope.—Ed.]

46. **Operation for Puerperal Mastitis.**—Hopmann describes the method of operative treatment of puerperal mastitis followed by Bardenheuer of Cologne. It avoids any disfigurement; leaves the milk glands nearly intact, especially those in the anterior portion of the breast, while the abscesses can be thoroughly evacuated and drained. A semi-circular incision is made around the lower half of the base of the breast, which is detached with the fingers from the fascia of the pectoralis major and turned back like a large flap. This allows ample access to the abscesses, which are opened by radial incisions and evacuated. A wide drain tube is left in each pocket and the breast is replaced. As the drains project in the most favorable manner for drainage at the lowest points, the abscesses heal rapidly. The only trace of the intervention is usually hidden by the overhanging breast. He has recently operated by the same technic in two cases of bursitis prepatellaris, making the incision below the knee, turning back the semicircular flap of soft parts and extirpating the bursa from below.

47. **Radical Operation of Femoral Hernia.**—Gilli mentions that he has discovered that operation is remarkably facilitated by cutting across Poupart's ligament and the falciform process (superior cornu). This not only favors operative intervention, but materially shortens the time required.

48. **Operation of Caput Obstipum.**—Wullstein not only relieves the caput obstipum by severing or partially removing the contracted muscle, but does not regard the operation as completed until he has shortened the unduly long, stretched part of the muscle, thus obviating the necessity for tedious after-treatment to accomplish this. He shows in a cut how easily the muscle can be shortened by taking up a loop in it, suturing the loop flap by sutures along the edges and occasional ones in the center of the flat expanse.

50. **Reduction of Dislocation of Hip Joint.**—Elgart has the patient recline on the floor and places the dislocated limb over his own knee as he kneels beside him on one knee at a right angle to the patient's body. By the leverage thus obtained reduction according to Kocher is rendered much simpler and easier.

51. **Costal Arch Flap for Operations on Hypochondrium.**—Marwedel makes a curved incision parallel to and a short distance from the costal arch, extending it from the ensiform process to below the tenth rib. The three ribs above are then divided at their cartilaginous union after pushing the muscles out of the way. It is then easy to turn back the soft parts and the ribs, leaving a broad opening into the cavity below, exposing the liver or the upper part of the stomach including the cardia and the subdiaphragmatic space. In two clinical cases in which this plan was followed the flap was cut and raised in a few minutes. The single abdominal wound healed by primary intention and seven weeks after the intervention the ribs were as solid as before.

53. **Resuscitation by Massage of Heart an Hour After Death.**—Sick reports that a lad of 15 was being operated on Dec. 13, 1902, at the Kiel clinic, on account of tuberculous peritonitis, when heart action and respiration ceased. Artificial respiration and König-Maas massage of the heart restored the respiration for a single minute or two, but it then subsided again, and after thirty minutes the youth was still cyanosed, pulseless, no respiration, the entire body growing colder and colder. The heart was then exposed by a Rotter incision and, forty-five minutes after the first signs of disturbance, massage was applied directly to the heart, supplemented by warm compresses. After fifteen minutes the heart gave signs of life, and in fifteen more minutes was beating regularly. Respiration was resumed, the pupils contracted to normal, the color returned and the pulse became good, although rather frequent. The pericardium was then sutured and the thorax flap replaced and sutured over the tampon. Two hours later the youth had regained consciousness and complained of thirst and dyspnea; respiration 60, pulse 144. Under camphor and saline infusion the condition remained about the same for twenty-four hours. The speech was indistinct, hurried but intelligible. Then symptoms of collapse were observed, the dyspnea increased and death ensued after three hours of coma. Signs of slight fibrinous pericarditis were found at the autopsy, and of old pleuritis, fresh recent tumefaction of spleen and liver, with tuberculosis of peritoneum and mesentery in an advanced stage. Sick remarks that the resuscitation might have been permanent in a subject less severely undermined. The action of the chloroform on the heart had evidently been magnified by the shock and the altered conditions in the circulation entailed by the laparotomy and evacuation of the ascites.

54a. **Action of Local Stimulation.**—Wessely describes experimental research on the eyes of rabbits which show that the application of warm compresses or local irritation induces a hyperemia accompanied by the rallying to the spot of the defensive antibodies in the serum. The proportion of albumin in the aqueous humor rose constantly from 1/40 per cent. to 1 and 2 per cent., and the agglutinating power increased ten to twenty fold. The same results were observed in the conjunctiva, which proved a particularly favorable field for these investigations. He notes that the proportion of albumin, etc., did not rise when the parts had been previously treated with adrenalin, thus confirming the fact that the phenomenon is connected with the hyperemia. It is evidently the secret of the benefits from hyperemia in inflammatory conditions.

54b. **Artificial Substitution of Blood.**—Küttner is convinced by the results of the researches of Locke and Kuliabko that a fluid, to be an efficient substitute for the blood, must contain oxygen. Experiments on animals showed that much more than the ordinarily fatal loss of blood was well tolerated by rabbits if the substituted solution was impregnated with oxygen. He illustrates a mechanism for the agitation of salt solution with oxygen to effect this impregnation.

54c. **Improved Anesthesia of Nerve Trunks.**—Braun's announcement in regard to the manner in which the action of cocain is magnified by the addition of adrenalin has already been mentioned in these columns. He asserts that five drops of the 1 per 1,000 solution of adrenalin is ample to add to a .5 per cent. solution of cocain to ensure perfect anesthesia of the superficial nerve trunks. For the large subfascial nerve trunks a 1 per cent. solution of cocain may be necessary. Sometimes thirty minutes may elapse before the nerve conductibility is entirely suspended, but in the knee or elbow the endoneural injection is followed at once by anesthesia. He advises to apply the constricting band—if one is required—only just before commencing the operation. The anesthesia obtained by this combination of adrenalin with cocain or eucain lasts from two to five hours.

55. **Radical Operation for Femoral Hernia.**—Herzen describes the technic with which he has been very successful. After the hernial sac has been tied and removed and the stump reduced, he detaches the femoral vein and draws it to one side and Poupart's ligament upwards. He then dissects a flap of periosteum from the upper aspect of the pubis about the width of the femoral canal and about 1 to 1.5 cm. long, its base on the pectineus. This flap is then detached from the bone and turned back downward. Two to four small holes are then drilled through the pubis in such a way that the drill emerges always in the part exposed by the raising of the flap. The two ends of a bronze-aluminum wire are then passed from behind forward through Poupart's ligament and through two of these holes. By pulling on the wire the ligament is brought into intimate contact with the exposed part of the pubis. The flap of periosteum is then replaced and fastened with a couple of stitches. By this means the femoral ring is entirely closed while the ligament has taken its place, reinforced by the periosteum flap. He has thus treated a consumptive patient, and in spite of his violent coughing, the results of the operation have been perfect, healing rapidly with absolute freedom from any tendency to recurrence of the hernia.

56. **Application of Adrenalin in Anesthetizing the Tissues.**—Braun proclaims that experience with several hundred patients has confirmed his previous assertions in regard to the great value of combining adrenalin with cocain. He warns now in regard to the dosage, as too large doses induce such pronounced anemia that it is impossible to ligate the vessels, and when the anemia gradually passes away after-hemorrhage is possible and liable. This after-hemorrhage is not due to the adrenalin, but to the fact that during the anemia there can be no question of arresting any hemorrhage. Consequently it is imperative to use only the amount of adrenalin necessary to enhance the anesthetic action of the cocain or eucain, and not to suppress all hemorrhage from even the larger arteries, causing them to contract to such extent as to close their lumen. A good combination is two to five drops of the 1 per 1000 adrenalin solution to 100 c.c. of a 1 per cent. solution of cocain or beta eucain. The proportion is then .00007 to .00017 per cent. of the adrenalin. Application of this mixture blanches the parts, but the larger arteries still bleed and can be ligated. The influence on the anesthesia is equally pronounced with these small as with large amounts. In extracting teeth or for endoneural injection two drops of the adrenalin solution are ample to each c.c. of the cocain or eucain solution. He has never used more than five drops, equivalent to about 1/6 mg. of adrenalin, in any instance.

65. **Origin of Pulmonary Tuberculosis and Means of Combating It.**—THE JOURNAL summarized on pages 1178 and 1266 of the last volume von Behring's important announcements in regard to the immunization of cattle based on the fact that the epithelial lining of the alimentary canal is not completely developed during early infancy, the gaps allowing the passage of albumin and bacteria like any very porous filter. The present article was an address at the Naturforscher Congress, in which he proclaims that time and experience have more than confirmed his previous statements. He reviews the brilliant results of the practical application of his method of immunizing cattle as carried out by stock raisers and dairy men, both in Germany and elsewhere, and states that the Prussian government is now considering the propriety of assuming the task of immunization of cattle by this method as an official department. Until recently Behring has carried it on from his private means. He maintains the identity of human and bovine tubercle bacilli, and preaches that the main source of phthisis occurring at any time during life is from infection through the milk taken during infancy, whether the tubercle bacilli in the milk are of human or bovine origin. The presence of a coughing consumptive in a family almost inevitably results in the infection of the infants by inhaling the germs or by their getting into the milk or on the vessels used. This is the secret of the so-called heredity and predisposition to tuberculosis in the members of a family. The infection is post-genital, not inherited. It may remain latent for years or for life, but under predisposing conditions it may develop into pulmonary tuberculosis, which is thus traced to infection in infancy. And it is to this age that we must apply not only prophylactic but immunization measures such as he has so successfully practiced in cattle. Immunity can be conferred by isopathic immunization or by antitoxin treatment. The former is the method followed with cattle, but is not feasible for children on account of its dangers at present. These will be obviated, however, if it proves possible to confer immunity by ingestion of the bacilli *per os* instead of the more dangerous intravenous route now in use. The prospects are more encouraging for immunization of infants by the antitoxin method. His hopes are becoming stronger and stronger, he says, that it will prove possible to confer immunity on infants by giving them the milk of highly immunized cows. The immunity thus obtained is not very lasting, but it may be supplemented by immunizing procedures with the living virus, such as have proved effectual in the prophylaxis of other diseases. One of the problems he is at present studying is to devise a means to preserve the antitoxin in the milk of the immunized cows so that it will keep and bear transportation. He speaks with commendation of Jousset's method of inoscopy as an invaluable means of detecting tubercle bacilli in the organic fluids. (See paragraph 44 above.) In regard to the tuberculin test, he mentions casually that Koch has reacted positively to the test, and that he himself ten years ago after a dose of 4 mgm. reacted with fever and was confined to bed for several days, thus convincing him of the tuberculous infection of his own body. He explains the reaction to tuberculin as the result of phenomena of coagulation and agglutination induced by the contact of this preparation of tubercle bacilli with the otherwise soluble antibody produced in the body by the action of the tuberculous lesion. He is inclined to believe that the smaller arteries in the vicinity of the infectious focus are the seat of the elaboration of this antibody. He reaffirms with emphasis that tuberculous infection is far from meaning inevitable phthisis. A combination of several factors is necessary for this result. He cites as an example the experience of Dr. M. Schmidt of Frankfurt, who, in his forty years of practice, has examined untold numbers of cases of tuberculosis of the larynx, and neither he nor any of his assistants have shown evidences of infection. Behring is hopeful of the day when immunization of man and cattle against tuberculosis will banish the sanatoria, etc., from the land as Jenner's vaccination has swept away the old-time smallpox hospitals in every town, but explicitly states that he has nothing definite yet to propose as far as man is concerned.

72. **Elimination of Sugar After Extirpation of Pancreas.**—Lüthje mentions in the first place that he was much surprised to find traces of the pancreas still left after what he supposed was absolutely complete extirpation. The microscope revealed particles of pancreas tissue *in situ*, which suggests that the contradictory results obtained in previous research may have been due to retention of more or less numerous scraps of the parenchyma. His experiments were all made on dogs, and even after complete removal of the pancreas the sugar did not disappear entirely from the urine until the animals had been kept for a time on a starvation nitrogen diet. The slightest addition of albumin to the diet—after the animals had been freed from sugar by being kept on the starvation diet—was immediately followed by the reappearance of sugar in the urine.

73. **Tests for Albumin in Concentrated Urine.**—Hallauer points out that the reaction to the albumin tests varies with the concentration of the urine, and consequently the latter should be diluted in case of a negative result to the test before accepting it as positively negative. After reduction of the urine to half its volume the most sensitive tests ceased to give the reaction previously obtained.

74. **Gas Gangrene.**—Dansauer reports a case and reviews the publications of others on the subject, and also the results of personal experimental research, concluding that the common colon bacillus is capable of inducing gas gangrene in the non-

diabetic living organism. It is not able to do this alone; its action is saprophytic and dependent on a primary local or general injury of the tissues from some nutritional disturbance either from trauma or deranged metabolism.

76. Focal Affection in the Pons.—In Steinert's 2 cases the presumptive diagnosis of a focal affection in the pons was based on a series of symptoms which he describes at length. The patients are still living and the diagnosis has not been anatomically confirmed. In the first case the paralysis of all the branches of the facialis was accompanied by hemiparesis, the Babinsky sign, hemianesthesia and violent hemihyperidrosis, but the pathognomonic symptom was the paralysis of certain ocular muscles for certain conjugated movements, normal for the rest. There was also transient paralysis of the palate on one side and absence of lachrymal secretion. Some of these symptoms subsided after a time and confirmed the assumption of an acute encephalitis pontis which had healed, leaving a defect. The inflammation was consecutive to a suppurative dental periostitis. Damianos has recently called attention to the possibility of a suppurative thrombophlebitis of the sinus cavernosus as a sequel to periostitis in the jaw. Among the symptoms presented by the second patient were complete lax hemiplegia, the Achilles jerk absent on the right side, the abdominal reflexes absent on both sides and the Babinsky sign present. After a time the Strümpell sign became evident on both sides. The gait was never that of a hemiplegic, but suggested that of ataxia. The patient was also annoyed by a sensation of heaviness in the entire right side, especially in that side of the head, and the atrophy of the muscles was more pronounced than usually observed in hemiplegia. The ocular disturbances were the same as in the first case, and vision was not impaired in either. [E. Schwarz of Riga reviews the differential diagnosis of pons affections in the *St. Petersburg Med. Woch.*, No. 35, and proclaims that absence of the pupil reflex on one side in the early stages testifies in favor of an intrapontine lesion, when noted in a syndrome suggesting involvement of the base of the brain. He describes 2 cases in detail with postmortem findings in one. The ocular symptoms are noted in the Oct. *Ophth. Record.*—Ed.]

77. Thirteen Years' Experience with Diphtheria.—Curtius is an ardent advocate of preventive serum treatment, and mentions among other points the comparatively slight disturbance of the general health at first in comparison with that observed in tonsillitis. He also refers to the confluent character of the exudation, which very seldom occurs in dots, but usually in masses. He orders the children to spit into a dish of water and in this way has often detected scraps of false membrane as the first sign of diphtheria. His experience has confirmed the great value of local applications of Löffler's solution applied on cotton and pressed into the spot after removal of the membrane, holding it in contact for ten seconds. The formula is menthol 2.5 gm.; dissolve in toluol 9 gm., alcohol 15 gm. and liq. ferri sesquichlor. 1 gm. He has found this very effectual even when serum treatment was impossible for any reason, but insists on the importance of removing the membrane before applying it. If the child will not open its mouth he pushes the lower lip over the lower teeth to keep the mouth open. He regards gargles as useful merely for the mechanical removing of bacteria and remarks that clear water is as good for this purpose as an antiseptic. He urges an abundance of nourishing food and strict cleanliness, as repetition of the infection is not impossible. As a homely measure to supply steam when the child is breathing with difficulty he throws a sheet over the bed, held up by barrel hoops or something of the kind, and generates steam by pouring water over a hot brick. This moist heat softens the rigid infiltrated tissues in the throat and stimulates the circulation in the parts, possibly also loosening the membranes.

79. Tuberculosis Infection By Way of Intestines.—Sorger states that he has fed dogs for months with tuberculous sputa mixed with their food, but always with negative results.

81. Absorption of Lime by the Tissues in Rachitis.—Pfaundler argues to prove that newly formed osteoid tissue does not possess any special affinity for the anorganic constituents of the true bone formed later. This affinity develops in the later course of the transformation of the osteoid tissue. A certain form of heteroplasia of the osteoid tissue is thus necessary for calcification, and it is further possible that under the influence of hydrolytic processes the elements of the osteoid tissue become able to take up lime. In calcification, acid radicals, and especially phosphoric acid, are found as well as lime. If these premises are correct the essence of rachitis may prove to be a defective transformation of the elements of the osteoid tissue into lime catchers, an inhibition of the normal biochemical tissue transformations, possibly in the line of autolytic processes. The unmistakable benefit derived from phosphorus in rachitis may be due to its favoring the hydrolytic splitting of the nitrogenous tissue-forming elements.

84. Cerebral Bladder Disturbances.—Friedmann had occasion to observe a boy of 9 who was affected with an almost isolated disturbance in the innervation of the bladder in consequence of a brick falling from a height on his head. The disturbances continued a long time, but finally subsided. From study of the case he assumes that the brick must have injured a point in the brain which serves as a center for the innervation of the bladder. The spot was close to the edge of the posterior central convolution, directly adjacent to the upper parietal lobule. The fact that the hand and arm were not affected to any extent shows that the center in question must be small and circumscribed, as the centers for the hand and arm are in close proximity to the point of the injury.

86. Aspirating Pipette.—In drawing blood for examination Ebstein uses a Pravaz syringe instead of a rubber bulb to aspirate the blood, applying the syringe to the end of a short, stiff rubber tube attached to the pipette. He remarks that we do not realize the inconveniences of the present methods of aspirating with a bulb until they are abolished by use of the syringe.

92 *Ueber Akromegalie. L. Huismanns.
93 *Casuistische Beitrag zur Eisenlichtbehandlung (Treatment with Iron Light). E. Clasen (Hamburg).

88. Fluids in Diet in Heart Disease.—Kraus makes a practice of occasionally restricting the intake of fluids at periodical intervals. If the subject is accustomed to take about 1500 c.c. he limits him to 1200, or even 1000 c.c., returning then to 1500 c.c. Many persons adapt themselves without trouble to as little as 1000 c.c. Valvular defects are not benefited to such an extent by this dietetic restriction of the fluids as cases of chronic insufficiency of the heart, especially those in which the compensation is just beginning to be inadequate.

89. Buttermilk in Infant Feeding.—Kobrak's experience with 66 cases at Neumann's clinic at Berlin impels him to recommend buttermilk as a valuable aid for the feeding of infants of the class that apply to the dispensary. It is especially indicated for weakly infants, the prematurely born and those with chronic atrophy and in moderate or mild cases of intestinal catarrh. Also when there is much vomiting.

90. Specific Treatment of Exophthalmic Goiter.—Burghart describes a preparation of condensed milk from thyroidectomized goats. It is a sweetish powder and is sold under the name of "rodagen." He has found it very beneficial in the treatment of exophthalmic goiter, either by the mouth or by subcutaneous injection. In 2 of the 10 cases he reports the eyes receded until the patients now consider themselves cured. He mentions that the goats lost their intelligent expression and became clumsy; their hair fell out and grew in again rougher than before. The secretion of milk gradually ceased, and the general appearance of the animals after the removal of the thyroid unmistakably suggested that of myxedema in man. One goat succumbed to the progress of the symptoms in-

duced by the thyroidectomy. The therapeutic use of the milk from these animals has an undoubted effect in neutralizing the toxin elaborated by the thyroid gland in abnormal conditions, but, of course, it can not influence already established anatomic changes. The serum and milk from the thyroidectomized animals have an unmistakable influence on the heart action and must be used with caution on this account, especially when the heart is already impaired. In all other respects the serum and rodagen proved harmless, even as much as 50 gm. a day, with no other effects than the more or less rapid retrogression of the subjective and objective symptoms. Some of his patients took 5 gm. a day; others up to 30 gm. In conclusion he announces as an established fact that treatment with the milk or serum of thyroidectomized animals has a favorable influence in a large proportion of cases of exophthalmic goiter.

92. **Acromegaly.**—Huismann ascribes this affection to a lack of hypophysis functioning, the result of a primary or secondary lesion in the hypophysis. It may be due to malignant disease or hypoplasia or hyperplasia, or may result from a primary chronic affection of the blood impairing the organ secondarily. Organ treatment will certainly benefit unless irreparable changes have already been established.

93. **The "Iron Light" in Radiotherapy.**—Clasen has been favorably impressed with the action of the iron lamp, especially in acne and sycosis. Its effects are more superficial than those realized with the Finsen light, but his experience with 17 patients has shown that the new lamp, being within the reach of every practitioner, can not fail to realize great progress in the treatment of cutaneous affections. For acne in particular it is the most convenient and agreeable method of treatment yet devised. In many cases in which the acne had persisted for years the skin healed over smooth after a few applications. He had only a single failure in his 14 cases, and this one patient did not complete the course recommended. There are no subjective sensations from the application of the iron light. (It has been described in these columns, xl, page 1112, paragraph 53.)

95. **Non-Operative Treatment of Angiomata.**—Frattini has invariably been able to cure cutaneous angiomata by painting them with a 6 per cent. solution of sublimate in collodion. He applies a second coat at once as soon as the first is dry, and repeats the procedure every third day. After the second or third repetition the angioma is cast off with the collodion, and nothing is left but a smooth surface, the color of the surrounding skin. In one case the angioma projected 3 cm. and was 4 cm. in diameter, but the cure was as prompt and perfect as in the other cases. No pains nor inconveniences were noted in any instance and the cures have been permanent with most satisfactory cosmetic results.

97. **Liberation of Iodin in Contact with Animal Tissues.**—Spadoni shows that iodin is liberated on contact with the tissues, but is taken up by them and is not eliminated at once. The lack of elimination must not be construed as evidence that the iodin has not been liberated.

98. **Digitalis as Specific for Pneumonia.**—Bragagnolo regards digitalis in large doses as an absolute specific for lobar pneumonia. Only 4 patients died in 54 treated in this way, and the deaths in these cases could be ascribed to other lesions. It reduces the temperature, slows the pulse and, if given early enough, will abort the disease. He follows Maragliano's technic, giving an infusion of 4 gm. of digitalis leaves by percolation with 200 gm. water, adding 100 gm. of licorice water and 2 gm. of anisated water of ammonia, the whole amount to be taken in the twenty-four hours. The benefit is apparent after four to six doses, and his experience has confirmed that of Maragliano, who says that if the pulse is not slowed in forty-eight hours by this medication the patient is doomed. The crisis occurred at the fourth day in 2; fifth day in 36; sixth day in 5; seventh day in 5; and the eighth day in 2. He resorted to venesection in a few cases toward the close of the disease, considering it of no use in the early stages.

99. **Chylous and Chyliform Effusions.**—Cipollina has always found that patients with chylous ascites did not long survive, but died in progressive cachexia. The effusion is profuse and may be accompanied by fever and signs of inflammation of the peritoneum. He describes a case of a chyliform effusion found in the pleura on the side which had been the seat of severe pleurisy thirty years before. He assumes that the effusion had remained encapsulated during this long period with granulo-fatty degeneration.

101. **Trigeminal Neuralgia.**—Baroni describes 2 cases of intractable trigeminal neuralgia cured to date by stretching the nerve at the periphery, breaking it off as high up as possible. One of his patients had had syphilis, malaria and trauma affecting the region. He believes that the percentage of cures after a simple peripheral operation of this kind is higher than that from the more serious interventions on the ganglia.

102. **Antitoxin Treatment by the Mouth.**—Figari reports extensive experiments with rabbits, dogs and asses treated with Maragliano's tuberculosis antitoxin by the mouth. In all the animals marked antitoxic, agglutinating and resisting powers were conferred on the animals by this means. The results suggest that the production of specific defensive substances is not the property of any given species, but is the expression of the general reaction of the animal organism. Persons and animals taking antitoxin by the mouth can not be regarded as immunized, but they are evidently exceptionally well guarded against tuberculosis infection by an unusual supply of Nature's protective substances.

103. **Leucocytosis Consecutive to Intravenous Sublimate Injections.**—Memmi reports a number of experiences from Patella's clinic at Siena, showing that intravenous injection of 2 to 4 mgm. of sublimate induced a moderate hyperleucocytosis, thus proving a valuable aid to the natural defenses. He has examined several patients a year after the injections and was never able to detect any disturbances nor induration of the vein. The maximum of the leucocyte reaction was obtained four to six hours after the injection; by the eighteenth to the twenty-fourth hour the leucocytes had returned to the original number.

109. **Suprarenal Treatment of Atony of the Bladder.**—Moresco was inspired by Vassale's success in the treatment of atony of the stomach with suprarenal extract, to apply it also in paralytic conditions of the bladder. He has found it equally effective in this condition, and reports that 2 patients were thus completely relieved and cured of retention from paralysis of the detrusor urinæ. He used ordinary adrenalin, which he states is much less powerful than Vassale's paraganglin, but he was unable to procure the latter at the time. He injected 150 c.c. every morning of a 1 per 50,000 adrenalin solution, leaving it in the bladder for an hour or more. After determining the tolerance of the bladder for this solution he increased the strength to 1 per 25,000. After four and six injections there were indications of spontaneous micturition,

and by the end of the second week the bladder could be spontaneously almost completely emptied, which had been impossible for a long time.

114 *Sulla cura della eresipela facciale. F. Sarcinelli.

110. **Cocain-Adrenalin Analgesia.**—Gangitano reports from Bologna that he has used the combination of cocain and adrenalin in more than 100 operations and has never had postoperative hemorrhage nor noted any inconveniences. Among the operations were one for resection of the upper jaw; ablation of a large goiter; a Roux gastroenterostomy and a total laryngectomy. He mentions the salient points in each case, calling special attention to the advantages of the method in 2 cases of bilateral Bassini in a subject with grave heart disease, and a total hysterectomy in an obese woman with an uncompensated cardiac defect. He found that it was possible to dilate strictures of the urethra, previously impermeable, after the cocain-adrenalin application, rendering the projected operation unnecessary. He agrees with King that postoperative hemorrhage is prevented by the formation of a clot during the period of vasoconstriction. He used a mixture of 9 c.c. of a .5 per cent. solution of cocain with 1 c.c. of a 1 per 1000 solution of adrenalin hydrochlorate.

112. **Physostigmin in Intestinal Atony.**—Curlo's communication issues from Maragliano's clinic at Genoa and is based on both experimental research and 18 clinical cases. He groups the latter according to the negative or positive results obtained and thus demonstrates that the drug finds its indications in coprostasis from intestinal atony. It stimulates and induces spasmodic action and increases peristalsis. It is therefore contraindicated in spastic conditions, in intestinal catarrh and in mucomembranous enterocolitis. As it increases the tonicity of the intestinal wall it proves a valuable aid in combating meteorism. The maximal daily dose, free from symptoms of intoxication, is 4 to 6 milligrams. The standard dose is 2 or 3 milligrams. The signs of intolerance are myosis of the pupils and sialorrhea. His experience seems to show that the best mode of administration is the salicylate of physostigmin in pills.

114. **Treatment of Erysipelas.**—Sarcinelli has found that erysipelas of the face healed rapidly under application of a thin cotton face mask impregnated with .25 to .5 per 1000 solution of sublimate, substituted every two hours by another similar mask impregnated with a 3 per 1000 salicylic solution. This alternation of the masks kept the surface moist, while a too energetic action on the part of the sublimate was guarded against. If blisters formed he applied topically to them either vaselin or an ichthyol salve, before putting on the mask. This method of treatment not only benefited the local lesions but reduced the general infection, the fever rapidly subsiding, and no further medication being needed except possibly some heart tonic.

120 *Treatment of Erysipelas with Potassium Permanganate. E. I. Martzinovski. — O lyetchenii rozhe margantzovokislym kaliem.

115. **Bronchial Asthma in Children.**—Stolkind has had occasion to observe 3 cases of typical bronchial asthma in children. In one instance it developed consecutive to a severe attack of la grippe. Eosinophile cells, Curschmann spirilla and crystals were found in the sputa. The patient was a boy of 8. The attacks occurred mostly at night and lasted for an hour and more. In the second case the asthma vanished after adenoid vegetations were removed. The third patient was a boy of 14, who had suffered from the asthma for four years. Tuberculosis was noted in other members of the family. The asthma was evidently of reflex origin in all of the cases.

117. **Syphilis and Surgery of Kidneys.**—Margulies describes a case of inflammation in and around the left kidney which was opened up on account of the severe chills and fever. The syphilitic nature of the trouble was seen at once and all symptoms vanished under specific treatment. The patient was a woman of 26.

120. **Treatment of Erysipelas with Potassium Permanganate.**—A compress moistened with a 1 per 1000 solution is applied to the erysipelatous patches. The results have been very favorable in Martzinovski's experience in 7 cases thus treated.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE NEUROLOGICAL PRACTICE OF MEDICINE. A Cursory Course of Selected Lectures in Neurology, Neuriatry, Psychology and Psychiatry. Applicable to General and Special Practice. With 177 Illustrations. After the Author's Class-Room Methods as a Teacher of Students. Designed for Students and General Practitioners of Medicine and Surgery. By Charles H. Hughes, M.D., President of the Faculty and Professor of Neurology, Psychiatry and Electrotherapy, Barnes Medical College. Cloth. Pp. 417. Price, $3.00. St. Louis: Hughes & Co.

FUNCTIONAL DIAGNOSIS OF KIDNEY DISEASE. With Especial Reference to Renal Surgery. Clinical Experimental Investigations. By Dr. Leopold Casper (Privatdocent an der Universität) and Dr. Paul Friederich Richter (Assistant der III Med. Klinik in Berlin). Translated by Dr. Robert C. Bryan, Adjunct Professor Genito-Urinary Diseases, University Medical College, Richmond, Va., and Dr. Henry L. Sanford, Resident Surgeon Lakeside Hospital, Cleveland. Cloth. Pp. 233. Price, $1.50 net. Philadelphia: P. Blakiston's Son & Co. 1903.

ELECTRO-STATIC MODES OF APPLICATION, THERAPEUTICS AND THE USES OF THE ROENTGEN RAY. By William Benham Snow, M.D., Professor of Electro-Therapeutics and Radiotherapy in the New York School of Physical Therapeutics. Second Edition, Revised and Enlarged. Contains More Than 100 Illustrations, Including Ten Full-page Half-tones, Showing the Various Methods of Posturing and Treating Conditions. Cloth. Pp. 302. Price, $3.00. New York: A. L. Chatterton & Co.

SURGERY, ITS THEORY AND PRACTICE. By William Johnson Walsham, F.R.C.S. Eng., M.B. and C.M. Aberd., Surgeon, Formerly Lecturer on Surgery and on Anatomy, St. Bartholomew's Hospital. Eighth Edition. With 622 Illustrations, Including 20 Sklagram Plates. By Walter George Spencer, M.S., M.B. Lond., F.R.C.S. Eng., Surgeon to the Westminster Hospital. Cloth. Pp. 1,227. Price, $4.50 net. Philadelphia: P. Blakiston's Son & Co. 1903.

PROCEEDINGS OF THE CONNECTICUT MEDICAL SOCIETY, 1903. One Hundred and Eleventh Annual Convention, Held at Hartford, May 27 and 28. Cloth. Pp. 465. Publication Committee: Gould A. Shelton, M.D.; Samuel B. St. John, M.D., and N. E. Wordin, M.D. Published by the Society. 1903.

ADENO-MYOME DES UTERUS. Von Thomas S. Cullen, Hülfsprofessor der Gynäkologie an der Johns Hopkins-Universität. Mit 45 Abbildungen im Text. Half Cloth. Pp. 91. Berlin: Verlag von August Hirschwald. 1903.

The Public Service.

Army Changes.

Movements of Officers of the Medical Department, U. S. Army, under orders from the Adjutant-General's Office, Washington, D. C., for the week ending Saturday, Sept. 26, 1903:

Amador, R. A., contract surgeon, will proceed, on the expiration of the leave granted him, to his home, New York City, for annulment of contract.

Darnall, Carl R., captain and asst.-surgeon, is relieved from duty in the office of the Surgeon-General of the Army, and will assume charge of the field medical supply depot in Washington, D. C., in addition to his duties in connection with the Army Medical School and as recorder of the Army medical examining board.

Fuller, Leigh A., captain and asst.-surgeon, is granted leave for fourteen days, on the expiration of which he will proceed to Fort Bayard and report at the U. S. General Hospital for duty.

Gorgas, William C., colonel and assistant surgeon-general, now on temporary duty as chief surgeon, Department of the East, will report for permanent duty as chief surgeon.

Gray, William W., major-surgeon, is detailed to represent the Medical Department of the Army at the annual meeting of the Tri-State Medical Society of Alabama, Georgia and Tennessee, to be held at Atlanta, Ga., Oct. 13 to 15, 1903.

Kulp, John S., captain and asst.-surgeon, is granted leave of absence for four months from about October 15.

Lippincott, Henry, colonel and assistant surgeon-general, by operation of law, under the provisions of the act of Congress approved June 30, 1882, is retired from active service. Colonel Lippincott will proceed to his home.

Perley, Harry O., major-surgeon, on the expiration of his present leave of absence, is directed to proceed to Fort Logan for duty.

Rich, Edwin W., first lieut. and asst.-surgeon, on his relief from duty at Honolulu, H. T., will proceed to Manila, P. I.

Torney, George H., lieutenant-colonel and deputy surgeon-general, now on sick leave at San Francisco, is relieved from further duty in the Division of the Philippines, and will assume charge of the medical supply depot at San Francisco, relieving Lieut.-Colonel Louis M. Maus, deputy surgeon-general. Lieut.-Colonel Maus will proceed to Fort Riley for duty.

Wells, George M., major-surgeon, is relieved from duty at Fort Bayard, to take effect on the arrival at that place of Captain Leigh A. Fuller, asst.-surgeon, and will then proceed to San Francisco and report for transportation to the Philippine Islands.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending Oct. 3, 1903:

Pharmacist S. W. Douglas, detached from Naval Proving Ground, Indian Head, Md., and ordered to the Navy Yard, Portsmouth, N. H.

Asst.-Surgeon W. S. Pugh, Jr., appointed an assistant surgeon, with the rank of lieutenant, junior grade, from Sept. 23, 1903.

Asst.-Surgeon M. V. Stone, when discharged from treatment at the Naval Hospital, New York, ordered home and granted sick leave until December 31.

Surgeon S. H. Griffith, detached from the Marine Barracks, Washington, D. C., and ordered to the *Minneapolis* and to duty as fleet surgeon of the Atlantic Training Squadron.

Asst.-Surgeon R. B. Williams, detached from the First Torpedo Flotilla and ordered to the Naval Hospital, Norfolk, Va.

Asst.-Surgeon F. M. Bogan, detached from Navy Yard, Washington, D. C., and ordered to the *Chauncey* for duty with the First Torpedo Flotilla.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospial Service for the fourteen days ended Oct. 1, 1903:

Assistant Surgeon-General George Purviance, granted leave of absence for ten days from September 21.

Assistant Surgeon-General H. D. Geddings, to proceed to Paris, France, to represent the United States at an International Sanitary Conference October 10, and, on its adjournment, to proceed to Berlin and Frankfort, Germany, and London, England, for special temporary duty.

Surgeon R. D. Murray, to proceed to New Orleans, and thence to Laredo, Texas, for special temporary duty. Reassigned to duty at Key West, Fla., effective May 15.

Surgeon Preston H. Bailhache, granted five days' leave of absence from Sept. 5, 1903, under paragraph 189 of the Regulations. To proceed to Trenton and Perth Amboy, N. J., for special temporary duty.

Surgeon D. A. Carmichael, relieved from temporary duty in the Hygienic Laboratory, and directed to rejoin his station at Vineyard Haven, Mass.

Surgeon C. T. Peckham, to proceed to Boston for special temporary duty. Bureau order of Sept. 28, 1903, directing him to proceed to Boston for special temporary duty, revoked.

Surgeon S. D. Brooks, to proceed to Savannah quarantine as inspector.

Surgeon J. H. White, granted extension of leave of absence for ten days.

Surgeon G. M. Guiteras, to proceed to Laredo, Texas, for special temporary duty.

P. A. Surgeon M. J. Rosenau, reassigned as director of the Hygienic Laboratory, effective April 27.

P. A. Surgeon C. H. Gardner, to proceed to Boston for special temporary duty.

P. A. Surgeon H. S. Cumming, to proceed to San Francisco for special temporary duty.

P. A. Surgeon H. S. Mathewson, granted leave of absence for forty-five days from September 22.

P. A. Surgeon R. H. von Ezdorf, to proceed to Laredo, Texas, and report to Surgeon G. M. Guiteras for special temporary duty.

P. A. Surgeon L. L. Lumsden, relieved from duty at Vineyard Haven, Mass.; directed to proceed to New Orleans and report to medical officer in command for duty and assignment to quarters.

P. A. Surgeon M. J. White, three days' leave of absence, granted by Bureau telegram of August 23, revoked.

Asst.-Surgeon W. C. Hobdy, granted leave of absence for seven days from Aug. 22, 1903, under paragraph 191 of the Regulations.

Asst.-Surgeon C. W. Vogel, granted leave of absence for two days from Sept. 17, 1903, under paragraph 191 of the Regulations.

Asst.-Surgeon R. E. Ebersole, to proceed to New Orleans and report to medical officer in command. To proceed to Houston, Texas, for special temporary duty.

Asst.-Surgeon E. M. Steger, to proceed to New York and report to Surgeon G. W. Stoner, Immigration Depot, for duty.

A. A. Surgeon G. H. Altree, granted leave of absence for eighteen days on account of sickness.

A. A. Surgeon Hugh Burford, granted leave of absence for thirty days from September 20.

A. A. Surgeon D. M. Echemendia, granted extension of leave of absence, on account of sickness, for seven days from September 3.

A. A. Surgeon E. E. Hallett, granted leave of absence for three days from September 26.

A. A. Surgeon W. A. Weldon, granted leave of absence for seven days from Aug. 31, 1903, under paragraph 191 of the Regulations.

Pharmacist J. Achenbach, granted seven days' leave of absence from September 9, 1903, under paragraph 210 of the Regulations.

Pharmacist F. S. Goodman, granted twenty-three days' leave of absence from September 10. To proceed to Washington, D. C., for special temporary duty.

Pharmacist F. R. Hanrath, granted leave of absence for twenty-one days from September 7.

Pharmacist S. W. Richardson, granted ten days' leave of absence from September 20.

Pharmacist C. H. Woods, to proceed to St. Louis, and report to medical officer in command for temporary duty.

Pharmacist M. Walerius, to proceed to Laredo, Texas, and report to Surgeon G. M. Guiteras for special temporary duty.

Pharmacist E. B. Scott, granted leave of absence for thirty days from September 5.

Pharmacist J. E. Beck, granted leave of absence for thirty days from September 14.

Pharmacist F. A. Southard, granted leave of absence for three days from Sept. 28, 1903, under paragraph 210 of the Regulations.

Pharmacist G. A. Morris, granted leave of absence for twenty days from September 14.

Pharmacist C. Stier, to proceed to Key West, Fla., and report to acting assistant surgeon in temporary charge for duty.

APPOINTMENT.

Edward M. Steger, of Texas, commissioned as assistant surgeon (recess) in the Public Health and Marine-Hospital Service, Sept. 4, 1903.

BOARDS CONVENED.

Board convened at Washington, D. C., Sept. 25, 1903, for the purpose of making physical examinations of candidates for appointment in the Revenue-Cutter Service. Detail for the board: Assistant Surgeon-General W. J. Pettus, chairman; Asst.-Surgeon A. J. McLaughlin, recorder.

Board convened at the Purveying Depot, New York, Oct. 5, 1903, for the physical examination of officers of the Revenue-Cutter Service. Detail for the board: Surgeon H. W. Sawtelle, chairman; P. A. Surgeon A. C. Smith, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Oct. 3, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, Sept. 19-26, 4 cases.
California: Los Angeles, Sept. 12-19, 2 cases.
Illinois: Belleville, Sept. 19-26, 3 cases; Chicago, Sept. 19-26, 2 cases; Danville, Sept. 19-26, 1 case.
Maine: Oldtown, Sept. 19-26, 8 cases.
Maryland: Baltimore, Sept. 19-26, 1 case.
Massachusetts: Fall River, Sept. 19-26, 2 cases.
Michigan: Detroit, Sept. 19-26, 1 case; Port Huron, Sept. 19-26, 3 cases.
Minnesota: Crow Wing county, Sept. 14-21, 23 cases; Stearns county, Sept. 14-21, 3 cases; Stevens county, Sept. 14-21, 1 case.
Mississippi: Natchez, Sept. 13-20, 1 case.
New York: Niagara Falls, Sept. 19-26, 2 cases.
Ohio: Cincinnati, Sept. 18-25, 1 case; Cleveland, Sept. 19-26, 1 case.
Pennsylvania: Altoona, Sept. 19-26, 1 case; Butler, Sept. 12-19, 1 case.
South Carolina: Charleston, Sept. 19-26, 2 cases.
Tennessee: Memphis, Sept. 19-26, 3 cases.
Wisconsin: Milwaukee, Sept. 19-26, 2 cases.

SMALLPOX—INSULAR.

Philippines: Manila, Aug. 1-15, 1 case, 1 death.

SMALLPOX—FOREIGN.

Austria: Prague, Sept. 5-12, 1 case.
Belgium: Brussels, Sept. 5-12, 1 death.
Brazil: Pernambuco, Aug. 1-15, 9 deaths; Rio de Janeiro, Aug. 23-30, 46 cases, 20 deaths.
China: Shanghai, Aug. 8-15, 2 deaths.
Colombia: Barranquilla, Sept. 6-13, 1 death.
Great Britain: Bradford, May 30-Sept. 12, 155 cases, 9 deaths; Dundee, Sept. 5-12, 3 cases; London, Sept. 5-12, 9 cases; Newcastle-on-Tyne, Sept. 5-12, 5 cases; South Shields, Sept. 5-12, 1 case.
India: Bombay, Aug. 24-Sept. 1, 3 deaths.
Netherlands: Amsterdam, Sept. 12-19, 5 cases.
Russia: Moscow, Aug. 29-Sept. 5, 1 case, 1 death; Odessa, Aug. 29-Sept. 5, 5 cases; Warsaw, Aug. 22-29, 1 death.
Turkey: Smyrna, Aug. 31-Sept. 6, 40 deaths.

YELLOW FEVER—UNITED STATES.

Texas: Laredo, Sept. 24-28, 13 cases, 3 deaths.

YELLOW FEVER—FOREIGN.

Colombia: Panama, Sept. 14-21, 2 cases, 1 death.
Mexico: Vera Cruz, Sept. 12-19, 35 cases, 10 deaths.
Venezuela: Cagua, Sept. 19, epidemic; San Felipe, Sept. 19, epidemic.

CHOLERA—INSULAR.

Philippines: Manila, Aug. 1-15, 32 cases, 24 deaths; provinces, Aug. 1-15, 1,991 cases, 1,492 deaths.

CHOLERA—FOREIGN.

China: Shanghai, Aug. 8-15, 2 deaths.
India: Calcutta, Aug. 15-29, 18 deaths; Madras, Aug. 15-22, 1 death.

PLAGUE—FOREIGN.

Africa: Cape Colony, July 26-Aug. 8, 1 case.
Brazil: Rio de Janeiro, Aug. 23-30, 19 cases, 10 deaths.
China: Hongkong, Aug. 8-15, 13 cases, 11 deaths.
Egypt: Alexandria, Aug. 22-28, 7 cases, 6 deaths; Damiette, Aug. 22-28, 7 cases, 5 deaths.
India: Bombay, Aug. 24-Sept. 1, 79 deaths; Calcutta, Aug. 21, 29 deaths.
New Caledonia: Aug. 29, 23 cases, 17 deaths.

CONSERVATIVE PERINEAL PROSTATECTOMY.

A PRESENTATION OF NEW INSTRUMENTS AND TECHNIC.*

HUGH H. YOUNG, M.D.

Head of Department of Genito-urinary Surgery, Johns Hopkins Hospital Dispensary.

BALTIMORE.

The literature of the prostate and its operative treatment has become so vast that I will not attempt to discuss the many valuable articles which bear on this subject, but will simply present a résumé of my own work and the problems which have presented themselves.

My first prostatectomy[1] was in 1898, a patient on whom a suprapubic opening had been made for drainage. At this operation a tremendous intravesical outgrowth of the middle lobe was found, and as there was very little enlargement of the lateral lobes, I enucleated the mass through the suprapubic wound, with the assistance of a finger in the rectum (Fig. 1), a method which has also been employed by Guiteras, and described[2] by him in 1900.

The next three cases presented no median enlargements, the hypertrophy being confined to the lateral lobes. Following the advice of Alexander, I used the combined method, removing the lobes through the perineal wound with the assistance of a suprapubic incision. Although the operation was tedious and extensive, these patients did well, and in a paper on the subject I said that Alexander's was the operation of choice, except for middle lobe cases.

My next four cases were characterized by considerable middle lobe enlargements, and I therefore used the suprapubic route, and was surprised to find that with the assistance of the finger in the rectum I could easily enucleate very large lateral lobes in one piece with the median without destroying the urethra. The operation was also very much quicker—it frequently being possible to complete the enucleation in 5 to 6 minutes, whereas the combined operation would frequently take nearly an hour.

The principal objection to the perineal route was the necessity of the suprapubic incision to push the prostate down into the perineum where it could be enucleated, and I then thought of having an instrument made with two blades, which could be inserted closed through a perineal urethrotomy, separated when in the bladder, and then used as a tractor to drag the prostate toward the perineum. This was in 1899, but I never had the instrument constructed, but continued to do all prostatectomies suprapubically. The results obtained were excellent, the greatest objection being the considerable hemorrhage following the operation, the great duration of the convalescence, and the occasional development of suprapubic hernia afterward.

In 1899 several patients came to me who were so old and so weak that I was afraid to even administer a general anesthetic, much less to do so severe an operation as a suprapubic prostatectomy. One patient, being unable to use a catheter, caused me to purchase a Bottini incisor, and the results which I obtained on extremely old and feeble men, under local cocain anesthesia, were indeed so marvelous that I adopted the Bottini operation as the method of choice in cases past 65 years of age, who were not in a prime surgical condition.[3] Using my instrument with interchangeable blades of different size[4] I was able to operate safely and radically on prostates of any size. I found it possible also to successfully attack large middle lobes by making an oblique incision with the cautery blade on each side of the pedicle, thus dropping it back out of the way,[5] where it would afterward atrophy. In two years I operated thus on 40 cases, with two deaths, only one of which was due to the operation. Of these 15 were over 70 and three over 80, with no deaths, and with cures in all these cases but one.

I feel sure that many of these patients would have succumbed had a suprapubic or a combined prostatectomy under general anesthesia been done with the subsequent prolonged recumbent posture. The use of cocain, the little shock and hemorrhage produced by the Bottini, and the rapidity of the convalescence—out of bed on the second or third day—were the factors which contributed to save them. Since then I have used the cautery incisions on many more cases, some just as old and as desperate as those described above, with similar gratifying results. But while I have demonstrated to my own satisfaction that the Bottini operation is the only safe and justifiable radical procedure in very feeble subjects, I have never ceased to make use of prostatectomy when fit subjects presented themselves.

The publications of Syms, Murphy, Ferguson, Bryson and others within the past two years caused me to turn my attention again to the perineal route. In studying the methods that have been proposed, the intravesical balloon, which Syms used to draw the prostate into the perineal wound, seemed to me to be much better suited to overcome the great objection to perineal prostatectomy, the depth of the wound with the consequent difficulty of reaching the lobes to enucleate them, than Murphy's hooks, Ferguson's capsular retractors or Bryson's suprapubic prevesical incision.

The rubber balloon did not, however, appear to me to be quite perfect in that it did not seem to furnish sufficient strength for the great traction which is necessary, and the fact that Syms[6] had acknowledged that he found a metal instrument devised by Gouley, which was passed like a sound into the bladder, of great assistance in pushing down the prostate, confirmed me in my opinion that while the idea of making traction by means of an instrument which could be introduced into the bladder through a perineal urethrotomy wound was correct, the method adopted by Syms—the rubber balloon and tube—could be improved on.

I therefore set to work to construct an instrument of metal for this purpose. After several months of experiment, during which I endeavored to discover and correct the faults of each model by operative use, the instrument was completed, as shown in Illustrations 2, 3 and 4. It consists of two fenestrated blades attached to shafts, one of which revolves around the other. When the two handles near the outer end which regulate the rotation are brought together the blades are approximated and in position for insertion into the bladder through the opening in the membranous urethra (Fig. 2). Once introduced above the intravesical limits of the prostatic lobes the blades may be separated by rotating blades away from each other (Fig. 3), when it is ready for whatever traction on its shaft may be necessary to draw the prostate well into the perineal wound. Before discussing the use of this instrument, however, I wish to discuss some problems of technic and conservatism which have been met.

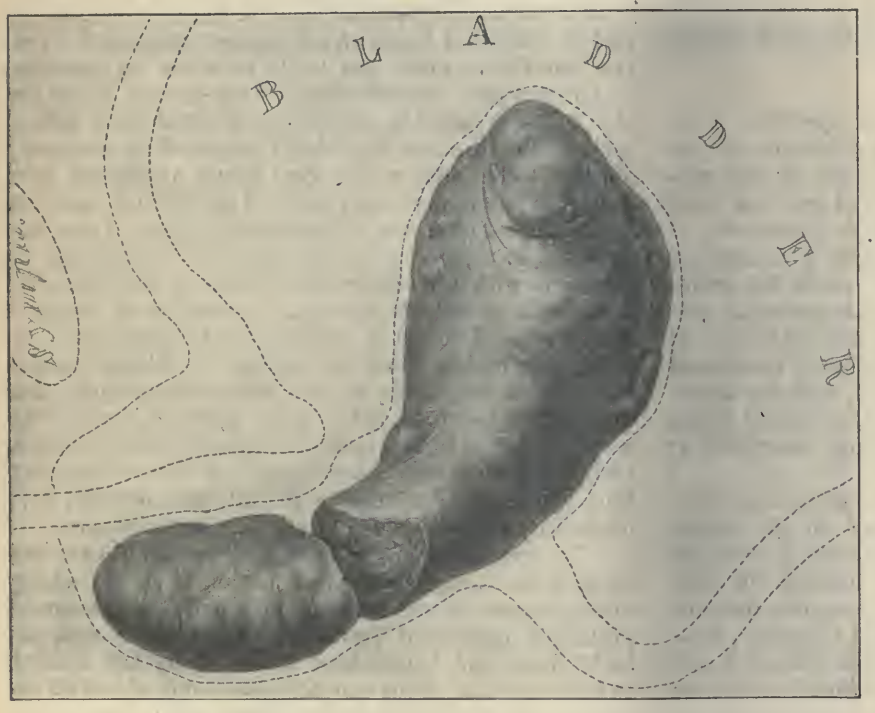

Fig. 1.—A large intravesical median lobe removed by suprapubic route. Actual size.

The Ejaculatory Ducts.—The fact that many of the cases requiring prostatectomy are vigorous men in the fifties, with sexual powers well preserved, renders it important to do nothing to injure their manly vigor.

In a recent report, Petit[7] furnishes the results of a careful study of Albarran's cases of perineal prostatectomy. He was able to follow 6 cases who had had normal sexual powers before the operation. Of these 2, both under 60 years of age, have never been able to have erections since the operation. In 2 cases the erections are much enfeebled; 2 cases are as strong sexually as before operation.

The operation is performed by Albarran without respect to the ejaculatory ducts, the prostatic urethra being opened wide in the median line, and the lobes enucleated through this incision. It would seem that the ejaculatory ducts are almost certain to be injured or removed in this procedure.

Petit mentions the work of other operators and concludes: "It seems to be shown that perineal prostatectomy diminishes if it does not suppress erections in some cases. But it is a curious fact that some cases operated on can still ejaculate." Another evidence of injury done to the ejaculatory ducts is that Petit reports that 12 cases in 30 suffered with epididymitis after the operation.

I know of no other statistics on these points. The three cases on whom I performed perineal prostatectomy by Alexander's method five years ago I have been unable to follow, and the twelve perineal prostatectomies which I have done in the past five months are too recent to draw final deductions from. Although the question needs further study, it is nevertheless evident that due attention should be paid, in performing the operation, to the importance of the prostate as a sexual organ.

In order to determine the relation of the ejaculatory ducts to the urethra and the prostatic lobes, I have made transverse and longitudinal sections in the specimens both of normal and of hypertrophied prostate.

The accompanying illustrations show very graphically the course of the ejaculatory ducts in the normal state (Figs. 5 and 6). As seen here, if we trace them backward from their urethral orifices we find that they rapidly approach the posterior capsule of the prostate; that the tissue separating them from the urethra gradually increases, and that the point of junction of the seminal vesicle and vas is reached considerably in front of the junction of the prostate with the bladder. Stained sections of the posterior portion show a considerable agglomeration of the glandular tissue surrounded by encircling muscular and connective tissue fibers which separate it more or less markedly from the glandular tissue of the adjoining lateral lobes. This mass of glands has been called by Albarran[8] the prespermatic group, and this it is which is most concerned in the production of median lobe enlargements. If this mass of glands (Fig. 5, A) is only slightly hypertrophied a median bar may be produced, which may be continuous with the lateral enlargements on each side, the whole forming a collar around the prostatic orifice. If, however, this group takes on considerable hypertrophy a sessile or

8. Albarran and Motz: Annales d. Mal. d. Organes Genito-Ur., July, 1902.

pedunculated intravesical median lobe, sometimes of huge dimensions, results. In these latter varieties another group of glands which lie just beneath the mucosa where the trigone joins the urethra, and which Albarran has called the subcervical group, may take part in the hypertrophy. All these median enlargements grow upward, away from the ejaculatory ducts, from which they are separated by considerable tissue, including their encapsulating fibers.

In the hypertrophied prostate the position of the ejaculatory ducts and vesicles depends considerably on the character, size and disposition of the enlargements. If the hypertrophy is great, and especially if a considerable median lobe is present, the vesical neck is generally found elevated far above the level of the ducts and vesicles, as shown in Figure 7, which is a longitudinal section of a prostate in which the lateral and median lobes are all three greatly hypertrophied. The ducts enter so low down on the posterior surface of the prostate that the median lobe is not in relation to them at all, and is separated from the vesicles by the prostatic capsule. It would, therefore, be easy to enucleate this lobe without injuring the ducts at all if properly done. Note here also the great width of the urethra, the proximity of its floor and the sharp bend which it makes in front of the middle lobe. Cross section A (Fig. 8) is taken where the utricle and one duct enter the urethra; B is taken a little farther back and shows the ducts midway between the posterior capsule and the urethra. Note the inverted Y urethra produced by the verumontanum below and the pressure of the lateral lobes against each other in front, and the slit-like character of the urethra. In C the ducts lie very close to the capsule.

Section D, which has been taken through about the middle of the prostatic mass, shows the junction of the vesicle and vas just outside the prostatic capsule. Note the greater distance of the urethral floor from the capsule. This is shown in still greater amount in C, and the vesicles and ampullæ are here seen to be separated from the median mass by the prostatic capsule. In F, which is taken about 5 mm. in front of the vesical orifice of the prostate, the further elevation of the median lobe is shown. The full extent of the median lobe is shown in the median section (Fig. 7).

Figure 9 is a side view of another specimen in which the vesicles and vasa join the prostate low down on the posterior surface.

In cases of little or no median lobe enlargement the hypertrophied lateral lobes seem also to carry the vesical neck upward and leave the vesicles and vasa behind, so that they are often found entering the capsule well down on its posterior surface, as depicted in Figure 9, the side view of a specimen of considerable hypertrophy of the right lateral lobe. The aponeurosis of Denonvilliers, which is firmly attached to the posterior surface of the seminal vesicles and of the prostate below their entrance, and which binds the two together closely, may be responsible for the upward growth of the hypertrophied prostate and the resultant low insertion of the ducts into the posterior surface.

The results of this study of the course of the ejaculatory ducts may be thus summarized:

In the normal prostate the ejaculatory ducts lie for the most part just beneath the posterior capsule, considerably below the level of the vesical neck, and are separated from it by the prespermatic group of glands.

In the hypertrophied prostate the same statements are true, the only difference being that the ducts enter relatively lower down, and the vesical neck is separated from them by much more tissue, especially if the prespermatic group of glands have taken on growth with the resulting median lobe enlargement, when the vesical orifice is lifted high up above the level of the ducts. The prostatic tissue immediately adjacent to the ducts is beneath the urethra and plays no part in the obstruction, which is caused entirely by the lateral and median enlargements, both of which are well above the ejaculatory ducts.

The measures which I have adopted to preserve the integrity of the ejaculatory ducts and sexual puissance of the patient I will take up a little later.

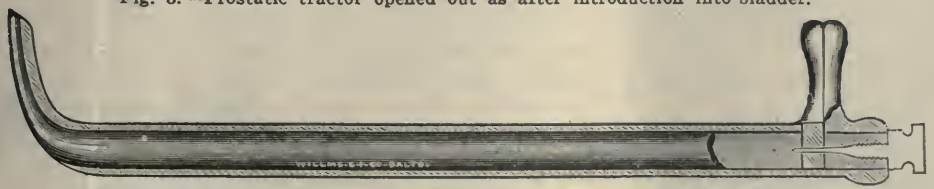

Fig. 4.—Sectional view, showing mechanism by which instrument can be taken apart.

TECHNIC OF THE OPERATION.

Position of the Patient.—The exaggerated dorsal lithotomy position is the most satisfactory. The perineal board of the Halsted table is admirably suited for this purpose. The perineum should be so elevated that it is almost parallel with the floor. Before placing the patient on the table a grooved sound, to be used as a guide for subsequent urethrotomy, should be placed in the urethra, as it is difficult to introduce it after the thighs have been flexed.

Cutaneous Incision.—If the patient is thin, and the prostate apparently close to the perineum, I use a

median perineal incision. This need not be more than 6 cm. long, the posterior limit being near the anus. The dissection is carried through the fat and superficial fascia when the wound is enlarged by lateral traction and the central tendon of the perineum, connecting with the bulb in front and the levator ani muscles behind, exposed. If the patient is a large man with thick perineal muscles, and the prostate is found, on

Fig. 5.—Longitudinal section of normal prostate. A, Prespermatic group of glands.

rectal examination, to be situated deep, or the perirectal fat is abundant, I generally use an inverted V-shaped incision, as shown in Figure 10. The apex of this incision is taken just over the posterior part of the bulb, and the two branches are each 5 cm. long, the posterior limits being about midway between the anus and ischial tuberosities.

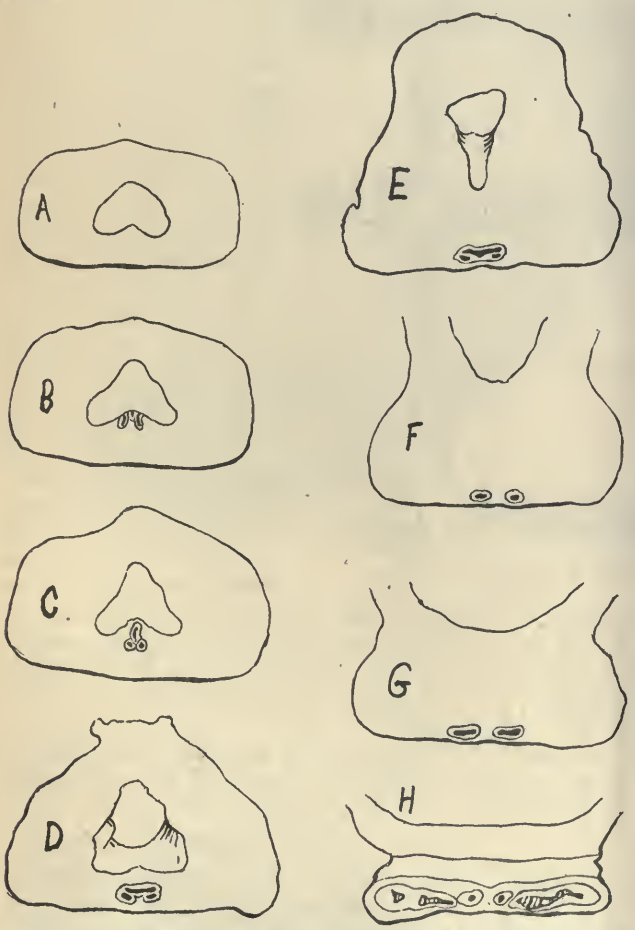

Fig. 6.—Cross section of normal prostate. A, At a point just in front of opening of ducts and utricle; B, at opening of utricle and ducts; C and D, 5-10 mm. back; E, at entrance into bladder; G, at the junction of seminal vesicles and ampullæ; H, the seminal vesicles and ampullæ separated.

I used to employ the inverted Y-shaped incision, but I have found the median portion along the bulbous urethra entirely unnecessary, as the field of operation is far behind that region. Zuckerkandl's crescentic incision gives, I think, an unnecessarily large wound.

The strenuous objections which have been urged by some to any other than a median incision, I think only apply when the lateral incisions are carried through the muscle. This I never do, and the inverted V incision gives me much more room, and allows the rectum to be retracted backward so much better that I think it is often preferable to a median perineal incision.

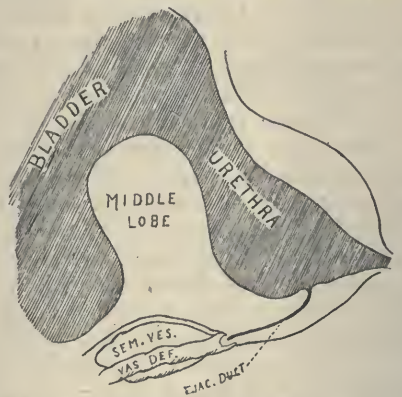

Fig. 7.—Longitudinal section of a prostate, with great hypertrophy of the median and lateral lobes. Urethra very wide and thin. Note low insection of ducts.

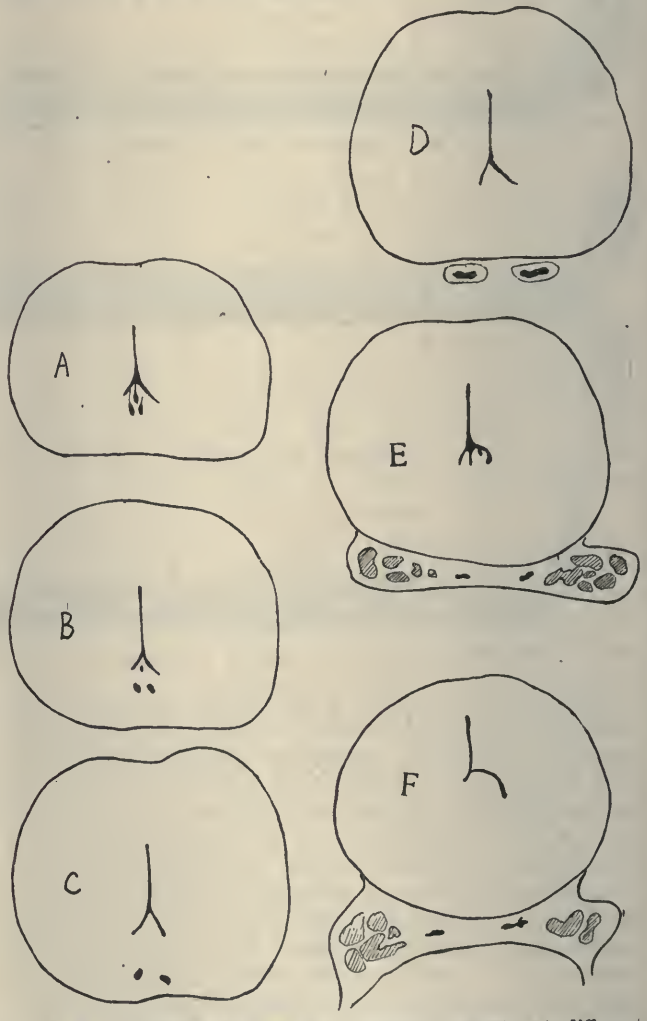

Fig. 8.—Six cross sections of the same prostate at different levels, as in Figure 6. The ducts rapidly approach the posterior capsule and in D are already outside of it. A shows the beginning of the median lobe, and F just before the entrance of the urethra into the bladder.

Exposure of the Membranous Urethra.—After the superficial muscles have been exposed by blunt dissec-

tion, as shown in Figure 11, the central tendon is caught by a clamp near the bulb and divided. This at once frees the sphincter and the levator ani from their anterior attachment, and exposes the rectum drawn forward by the recto-urethralis muscle, as seen in Figure 12. The recto-urethralis is a short muscle with rather indefi-

Figure 9.

Figure 10.

Fig. 9.—Side view of hypertrophied prostate, showing low entrance of ducts on posterior surface.
Fig. 10.—The inverted V cutaneous incision.

nite margins, which, as its name indicates, joins the rectum with the urethra. It is apparently responsible for the acute anterior flexure of the rectum which lies so close to the apex of the prostate and membranous urethra and which one finds in rectal examinations. In

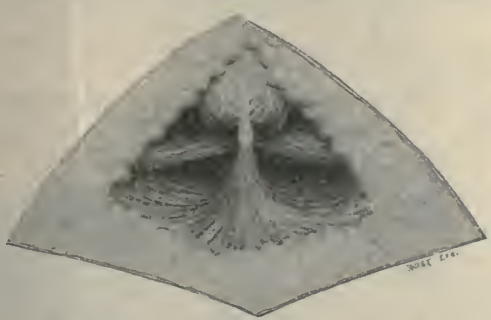

Fig. 11.—Exposure of bulb, central tendon and levatores ani.

order to reach the membranous urethra and the apex of the prostate, it is necessary to divide this muscle, as shown in Figure 13. This at once exposes the *"espace decollable retroprostatique"* which has been so well de-

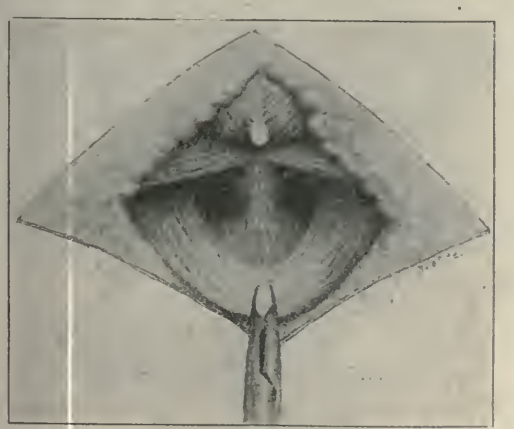

Fig. 12.—After division of central tendon. Exposure of recto-urethralis muscle.

scribed by Proust,[9] who has shown that unless this muscle is divided the operator is apt to tear into the rectum, which is drawn forward by it. Division of this muscle allows the rectum to drop back, and leads at once into the space surrounding the posterior surface of the prostate.

Urethrotomy and Insertion of Tractor.—After the membranous urethra has been exposed by division of the recto-urethralis muscle a retractor is inserted and the apex of the prostate brought into view, as shown in

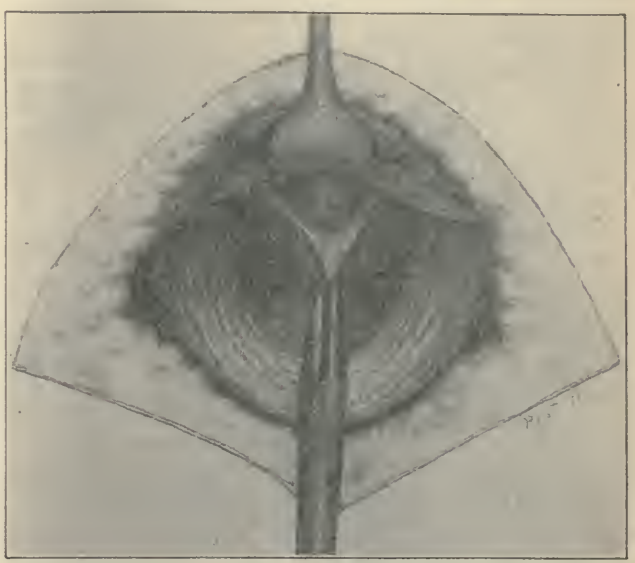

Fig. 13.—After division of recto-urethralis, exposure of membranous urethra.

Figure 14. The membranous urethra is then opened on the sound, which was inserted in the urethra before the patient was put in the lithotomy position, and the edges of the urethral wound caught up by silk sutures or by Kocher clamps. A sound of moderate size is then

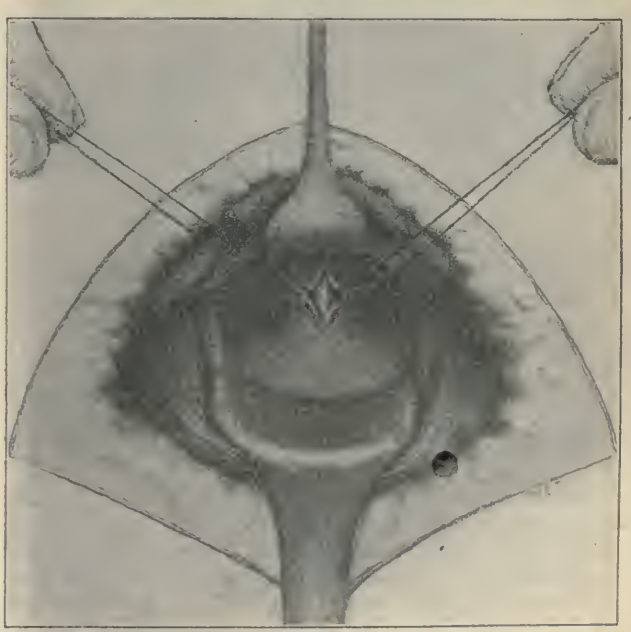

Fig. 14.—Opening of urethra on sound, preparatory to introduction of tractor.

passed through the incision into the prostatic urethra and bladder, and the sphincters dilated by a to-and-fro motion of this instrument.

The prostatic tractor, closed (Fig. 2), is then passed into the bladder, the edges of the urethral wound being held open by the silk sutures to facilitate its introduc-

tion. As a matter of fact, I have never experienced any difficulty in introducing the instrument, the caliber of which is only about No. 30 F.

As soon as the beak is free in the vesical cavity the thumb screw which fixes the blades in position is loosened, the blades rotated 180 degrees by means of the external blades, and then fixed by tightening the thumb screw.

The instrument is now ready for whatever traction may be necessary to draw the prostate well down into the perineal wound, as shown in Figure 15. Figure 16 shows the position of the blades in the interior of the bladder, each blade projecting laterally so as to engage the intravesical surface of the lateral lobe.

Exposure of Prostate and Incision of Capsule.—Lateral retractors are so placed that with the posterior

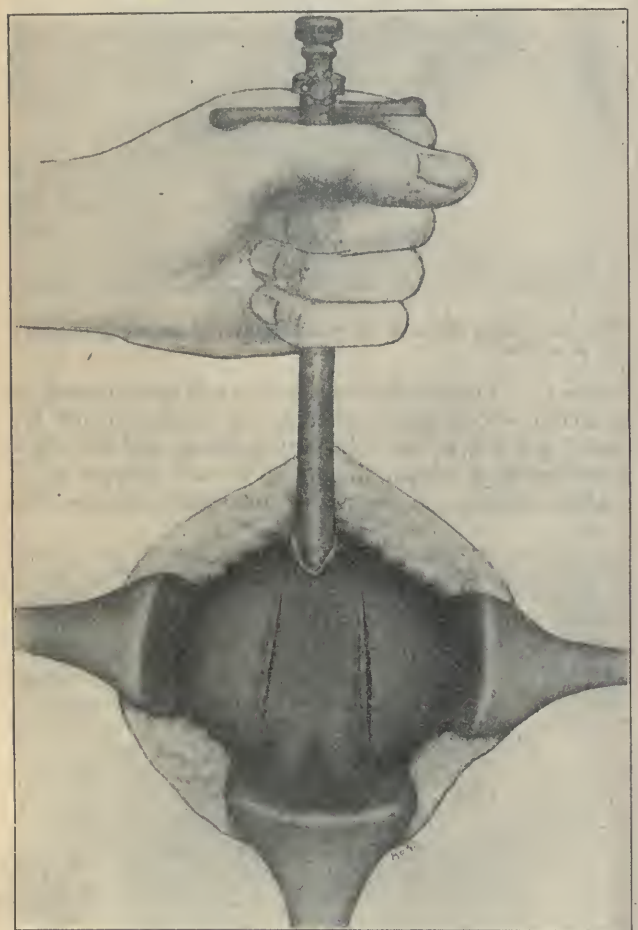

Fig. 15.—Tractor introduced; blades separated; traction made, exposing posterior surface of prostate. Incisions in capsule on each side of ejaculatory ducts.

retractor drawing the rectum backward, and the prostatic tractor drawing the gland outward, a splendid exposure of the entire posterior surface of the prostate is obtained. These retractors should not be too deep. An incision is then made on each side of the median line for almost the entire length of the posterior surface of the prostate and about 1 cm. deep. The two lines are convergent, as shown in Figure 15, being about 1.8 cm. behind and 1.5 cm. apart in front. The bridge of tissue which lies between them contains the ejaculatory ducts, and its preservation is of utmost importance, if the integrity of these structures is to be left uninjured. It is for this purpose that I make the initial capsular incision 1 cm. deep on each side, as these define at once, and correctly, the width of the "ejaculatory bridge," and prevent its being torn, as might happen if we depend on blunt dissection. Another advantage is that these incisions bring us at once to the side of the urethra where the internal enucleation (urethra from inner surface of lobe) can be easily accomplished later on.[10]

Enucleation of Lateral Lobes.—We are now ready to begin the external enucleation, the separation of the capsule from the lateral lobes, which is best done with the blunt dissector, as shown in Figure 17. Capsules are of varying thickness, and contain several layers of

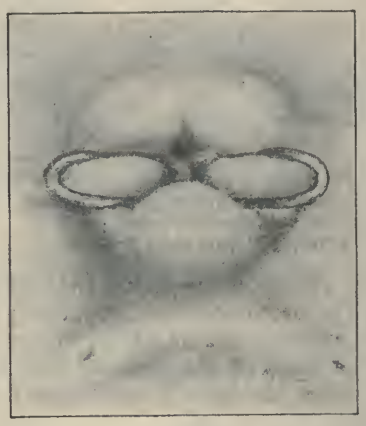

Fig. 16.—Showing position of blades in interior of bladder in case of median and bilateral hypertrophy.

cleavage. It is important to start the separation in the right layer, not too deep as you may be led into the substance of the lobe, and not so superficially as to be out-

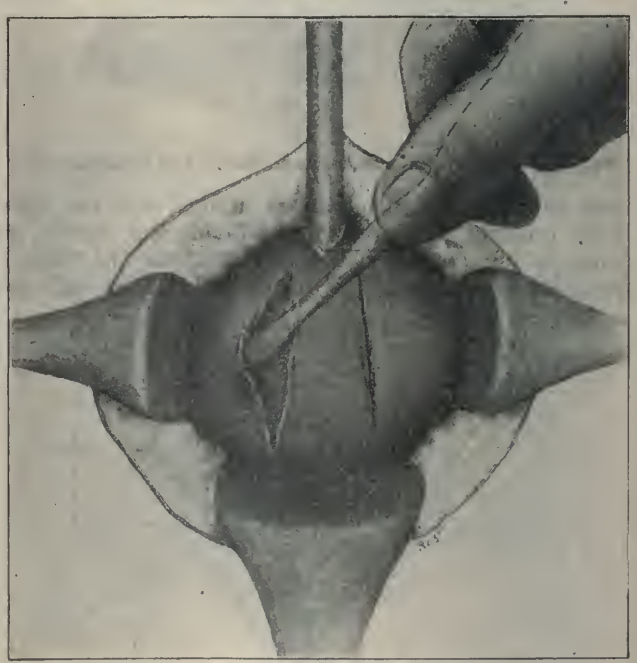

Fig. 17.—External enucleation begun.

side of most of the capsule. After the stripping up process has been started correctly it is easily continued by blunt dissectors until first the lateral and then the

10. Various capsular incisions have been proposed, e. g., Alexander used a transverse incision, Ferguson an elliptical, Albarran, Bryson and others a median, etc. Murphy advised parallel longitudinal incisions similar to those I use, but with the idea of avoiding the vessels in the median line and not, I believe, from any desire to save the ejaculatory ducts, for he afterward deliberately cut away the bridge which contains them, with the idea of preventing muco-cutaneous fistulæ: Discussion on prostatectomy, American Medical Association, Saratoga, 1902, THE JOURNAL A. M. A., Oct. 25, 1902.

anterior surface of the lateral lobes have been freed from the capsule. When the deeper portion is reached I use a special long curved blunt dissector.

The internal enucleation should be taken up after the external, as it is a much more delicate procedure and often requires considerable care to prevent tearing into the urethra. As remarked above, the primary incision is made with the scalpel until the level of the urethra is reached, after which the blunt dissector is used. During this procedure the shaft of the prostatic tractor is grasped firmly in the operator's left hand (Figs 15, 17 *et seq.*) and serves not only to draw the prostate so well down into the skin wound that every procedure is done in plain view, but to steady the prostate and mark out the course of the urethra so that it can be avoided.

Fig. 19.—Sectional view of blades.

When the enucleation of a lateral lobe has progressed fairly well on each side, it is advantageous to have traction made on the lobe itself in order to facilitate the separation of the deeper portion. I tried various instruments—vulsellum forceps, pedicle forceps and hook retractors—for this purpose, but I found that all toothed instruments quickly tore through the friable tissue whenever traction sufficient to be of any assistance in drawing out the lobe was used. It, therefore, seemed advisable to have fenestrated forceps which could grasp the entire lobe, and present such broad surfaces to it that no cutting or tearing of the capsule would be done. I accordingly designed the instrument shown in Figure 18. As seen in Figure 20, the two blades grasped the prostate with broad surfaces, so shaped as to hold, but not to cut, the lobe when the pressure is applied (Fig. 19). These forceps I have now used in four cases, and have found them of great assistance.* The lobes have come out in one piece, and I have been able to apply very great traction without tearing them, thus greatly facilitating the deeper enucleation (see Fig. 20). Nearly all of the enucleation is done with the blunt dissector, but when the intravesical portion of the lateral lobe is reached I generally use the finger so as to avoid tearing through the thin mucous membrane covering it. The intravesical blade of the prostatic tractor, which can be distinctly palpated through the mucous membrane by the enucleating finger, serves to direct the separation of the deeper portion, and warns against tearing into the bladder. It also shows when some of the lobe has been left behind. The conditions present after the enucleating of the two lateral lobes, as described above, are shown in Figure 21. As shown in this schematic cross section, the urethra, which contains the tractor, is left intact. Beneath is the bridge of tissue surrounding the ejaculatory ducts. The empty capsule is shown on each side.

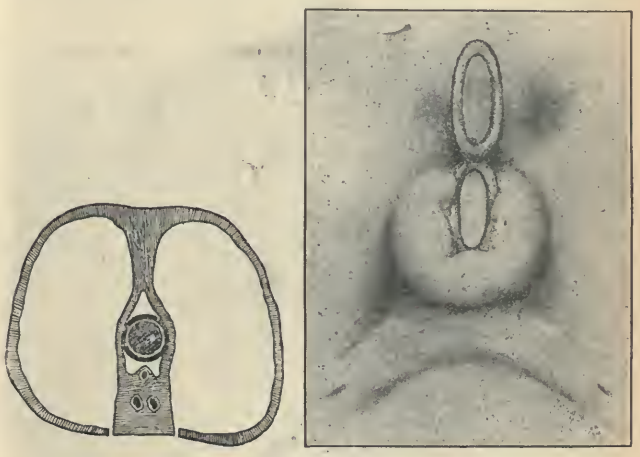

Figure 21. Figure 22.

Fig. 21.—Schematic cross section after enucleation of lateral lobes, showing ducts and median bridge of tissue. Instrument in urethra.

Fig. 22.—The blade rotated so as to engage middle lobe.

Enucleation of the Middle Lobe.—After the lateral lobes have been shelled out, attention should be directed to the median portion of the prostate. If the previous cystoscopic examination has demonstrated a thin transverse bar, it would often be found that removal of the lateral lobes has allowed it to collapse, showing that it was really an artefact, a fold of mucous membrane

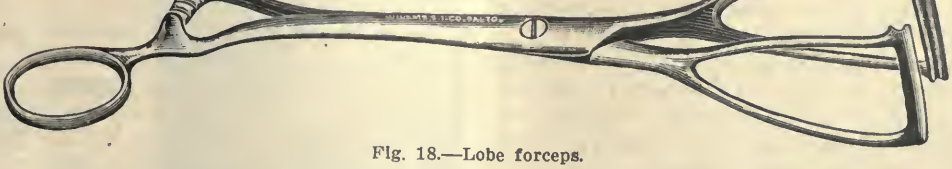

Fig. 18.—Lobe forceps.

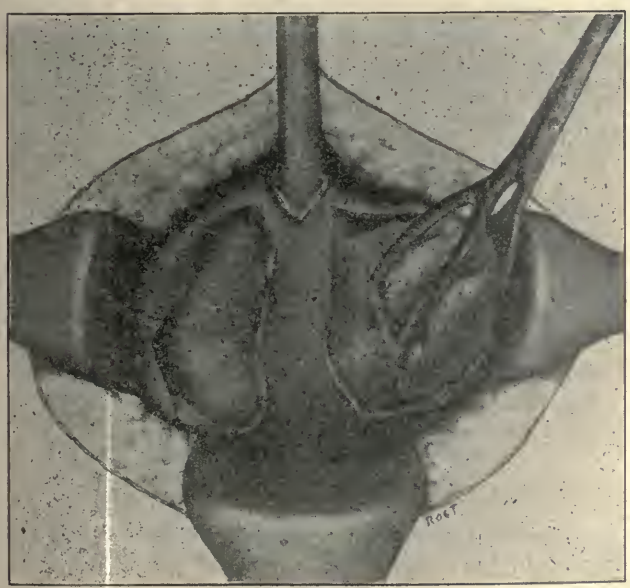

Fig. 20.—Enucleation of lobes. Forceps in position.

* I have since used them in many more cases, and found it desirable to have a smaller size made for small lobes.

hooked up by the lateral outgrowths, and not containing any hypertrophied tissue.

On the other hand, there is most often a more or less extensive hypertrophy of the prespermatic group of glands, and the mass can be easily seen, or felt by the finger in one of the intracapsular cavities (Fig. 23). Further examination will generally reveal a fair amount of tissue between the median lobe and the region of the ejaculatory ducts, which, as I have previously pointed out, lie well forward on the posterior surface, and close to the capsule. The median enlargement is generally more or less definitely attached to one or both of the lateral lobes and is oftentimes already so loosened from its encapsulations that there is no difficulty in shelling it out through one of the lateral cavities—without disturbing the integrity of the ejaculatory ducts and prostatic tissue immediately surrounding them.

The prostatic tractor may be used with great advantage in removing a median lobe, and the technic which I generally employ to draw it down into one of the lateral cavities where it can be enucleated, is as follows:

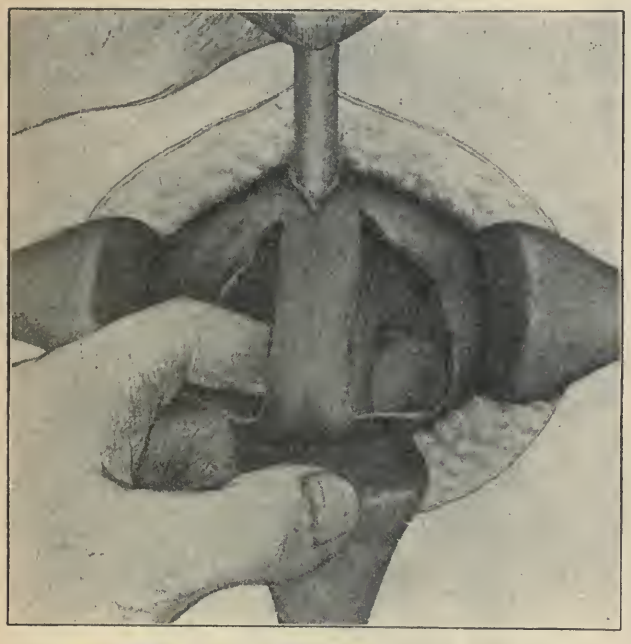

Fig. 23.—Showing technic of delivery of middle lobe into cavity of left lateral lobe.

Push the tractor backward until free in the bladder cavity, depress the handle of the instrument so that the shaft can lie on the top of the middle lobe, and then rotate the instrument 90 degrees, so that one of the blades projects downward behind it. Outward traction should then engage the lobe, as shown in Figure 22, and draw it down where it can be seen by the operator. To get it into one lateral intracapsular cavity (say the left) two maneuvers are of help: Pushing against it with the index finger of the left hand, which has been inserted in the right intracapsular cavity, as seen in Figure 23, and rotation of the blade engaging the middle lobe in the same direction, making traction on it all the while.

After the median lobe has presented in the left intracapsular cavity, the operator turns the tractor over to an assistant who continues the traction, while he grasps the lobe with the forceps described above and then rapidly enucleates it.

The above technic, which I am afraid I have described at too great length, has enabled me to enucleate several median hypertrophies without tearing the mucous membrane covering them.

In two instances I have found the median mass to be directly continuous with the left lateral lobe, and when the deeper portion of that lobe was being freed, that the median lobe was disposed to come with it. I have then rotated my tractor so as to engage the median,

Figure 24.

Figure 25.

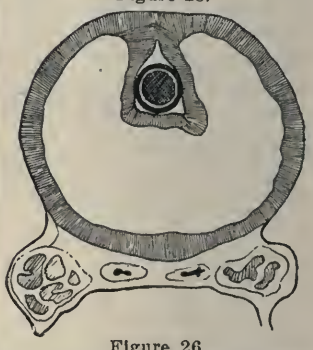

Figure 26.

Fig. 24.—Photograph of prostate in which the left and median lobes were enucleated in one piece. Exact size.

Fig. 25.—Longitudinal section after enucleation of median lobe through a lateral cavity.

Fig. 26.—Cross section at level of cavity left by median lobe.

and have readily drawn it down and enucleated the two in one piece, as shown in Figure 24. In another case a collar-like growth, consisting of a median bar and two lateral masses, was easily enucleated in entirety through the left intracapsular cavity without tearing the ducts

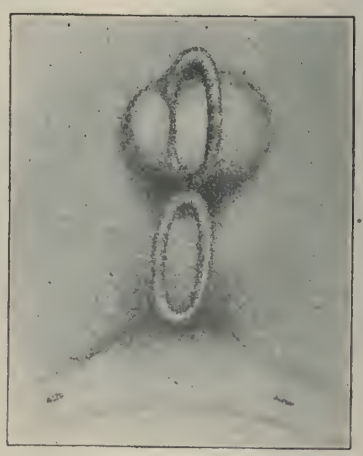

Fig. 27.—Blade engaging anterior lobe.

beneath or the mucous membrane of the urethra or bladder.

I have not as yet had a case with a very large median lobe. In such a case there might be difficulty in getting a blade of the tractor to engage and hold on the summit of the lobe while great traction was made on it.[11] Enormous median lobes, as depicted in Figure 1,

11. Since writing this I have removed a pedunculated median lobe through the left lateral cavity, by the maneuvers described above.

had best be removed suprapubically, as was done in that case; but I believe that it will be possible to remove median lobes of considerable size perineally, and that without destroying the ejaculatory ducts, as outlined above. (I believe now—June 1—that even great intravesical hypertrophies can be removed through the perineum, as in a recent case of mine.) The conditions present after the enucleation of a median lobe as described above is shown in the schematic Figures 25 and 26. Figure 25 is a longitudinal section showing the cavity left by removal of this lobe, the ejaculatory ducts being below and in front, at quite a distance from it. In Figure 26 the median cavity is seen to communicate with the two lateral in each side, beneath the intact urethra. The seminal ducts are separated from the capsule by the posterior capsule.

The Removal of an Anterior Lobe.—The presence of a definite isolated anterior lobe is such a rare occurrence that it hardly need be considered. We occasionally see with the cystoscope small anterior outgrowths, but they are generally continuous with a lateral lobe.

One of my cases was of this character, and, although it looked through the cystoscope like a large rounded mass, I found that it came away easily with the left lateral lobe. I employed a procedure the reverse of that which I have just described for posterior middle lobes, the anterior lobe being engaged by a blade which was directed upward, as shown in Figure 27. The entire mass (left lateral and anterior lobe) was very large, measuring 7x6x5 cm.

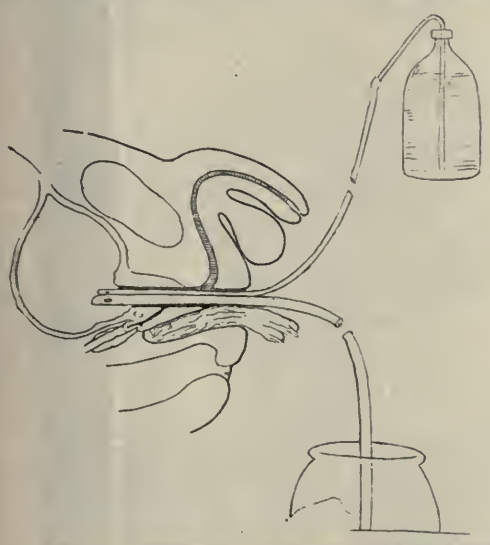

Fig. 28.—Scheme of continuous irrigation apparatus.

Fig. 29.—Two lobes removed by perineal prostatectomy. Actual size.

The ability to make traction on any desired portion of the prostate is of the very greatest value and assistance, especially in enucleating these unusual outgrowths of the hypertrophied gland.[12]

Drainage.—Before withdrawing the tractor, a careful examination should be made by inserting the finger into both of the lateral cavities and palpating the blades through the vesical mucosa, in order to determine that no important glandular mass has been left behind. The tractor is then removed by first rotating the blades until they come together and then withdrawing the instrument. Abundant vesical drainage should be provided, as a small tube may easily become plugged by blood clots and give great annoyance afterward.

I now use the two tubes, one a small catheter and the other an ordinary tube about 1 cm. in diameter. These are fastened together by ligatures at four places, about one inch apart and are prepared before the operation, so that as soon as the tractor is withdrawn they can be inserted through the perineal wound into the urethra and bladder. The catheter is immediately connected with a tank of normal salt solution, and the bladder thoroughly washed clean of blood. It is often advisable to keep the continuous irrigation going while the patient is being returned to his room so as to prevent clogging of the drainage tube with blood clots during transit.

After the tubes have been properly adjusted, they are tied by a heavy silk suture to the skin at the upper angle of the wound. The lateral prostatic cavities are then firmly packed with gauze and additional packing is placed in the retroprostatic space. The tube and gauze drainage as thus provided is shown in Figure 28.

Partial Closure of Wound.—If the median perineal incision has been used, the posterior portion is closed by buried catgut for the muscle, and silk or catgut interrupted for the skin. While no important muscles have been divided (only the central tendon and the recto-urethralis muscle), it is nevertheless advisable to draw together the structures which have been so widely separated by retraction.

If the inverted V incision has been employed, I sew up the muscle and skin completely on one side. The object of this is to restore the perineum to as nearly normal a condition as possible. The other limit of the

12. During the preparation of this paper I find a reference by Petit to an instrument designed by Albarran to depress the prostate. No illustrations are given but, from his brief description, the idea seems to be similar to mine. The fact that it did not prove successful would seem to indicate that there were marked differences in the construction. The instrument which he called a "désenclaveur," is described as follows:

"La désenclaveur est un désenclaveur à deux branches; chaque branche, aplatie, siège à l'extrémitie de deux tubes emboîtés l'un dans l'autre. L'instrument est introduit fermé dans la vessie par la boutonnière uréthral comme le serait un cathéter coudé, c'est-à-dire avec ses deux branches superposées. Une fois dans la vessie, les deux branches sont écartées à l'aide d'un levier externe construit sur le principe de celui d'un lithotriteur. Un index indique la direction donnée aux branches, et l'on cherche ainsi à abaisser le col vésical dans la but de désenclaver la prostate. Ce désenclaveur a été utilisé dans un certain nombre des cas, mais il nous a toujours donné des résultats insuffisants."

[PARIS, Aug. 1, 1903.—Since my arrival here I have found in the shops two other "désenclaveurs," one by de Pezzn and one by Legueu. The former is similar in some respects to my tractor, but it is very much smaller, and is only used to depress the prostate while the prostatic urethra is incised. It is then removed, not being used to assist in the enucleation of the lobes—for which it is manifestly too small to be of any service. Neither author has published a description of his instrument, so far as I know. H. H. Y.]

inverted V and the stretched muscles beneath are partially closed posteriorly, leaving a small opening for the rubber gauze drainage in front.

Using this method of closure there is no more distortion of the perineum after this incision than after the median. And there should not be, as there is no more destruction of muscular continuity in one than in the other; in fact, they only differ in the cutaneous incision.

After-Treatment.—The patient is generally returned to his room accompanied by an assistant who sees that

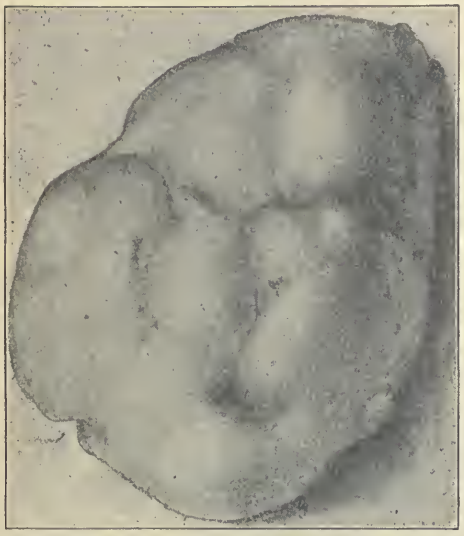

Fig. 30.—Coalescent lateral and anterior lobes removed in one piece. Actual size.

the irrigation is going well, and arranges to have it continued after he has been placed in bed. The apparatus used is indicated in the drawing. The flow is regulated by a screw clamp in the inlet tube. The outlet tube drains into a jar by the side of the bed. If the end is kept immersed in water, air can not get up the tube, and siphonage is obtained, thus keeping the bladder

Fig. 31.—Photograph of a pedunculated median lobe which was removed through the cavity left by left lateral lobe without tearing urethral or vesical mucosa. The three lobes are shown in exact size.

empty and preventing leakage around the perineal tubes. This siphonage is particularly important in suprapubic cases where the drainage is uphill. If the patient has a cystitis (and most have) a continuous irrigation of the bladder with salt solution is kept up often for a week, and, I have found, with great benefit to the vesical inflammation. The task of keeping the reservoir supplied with salt solution is not a difficult one, the nurse having to add a quart about every half hour. It is not necessary to maintain an even temperature—110 to 120 F. in the tank is about right—and the temperature is maintained between these fairly well by the half hourly addition of the hot salt solution. We have also a more elaborate apparatus with the Bunsen burner beneath, but find the simpler method sufficient.

A submammary infusion of 1,000 c.c. salt solution is given either on the operating table or after the return to bed. This is considered so valuable, both as a preventive to shock and anuria, and as a cure for postoperative thirst, that it is never omitted.

The patient is generally kept in bed a week, when the drainage tubes are withdrawn. The gauze drains are loosened on the second day and gradually withdrawn, all of the original being out by the sixth day. The superficial portion of the wound is afterward kept open by a small pack, so as to induce healing from the bottom. On the ninth day, after passing a sound, a small catheter is inserted through the meatus into the bladder,

Fig. 32.—Photograph of large intravesical hypertrophy of median and lateral lobes removed through the lateral cavities without tearing the urethra.

and held in place by straps. Permanent drainage is thus maintained for five days, the bladder being irrigated twice daily with boric solution. When the catheter is withdrawn a good portion of the urine will be found to come through the perineum, but in a short time almost all will come through the meatus, though it is sometimes five or six weeks before the minute perineal fistula closes. I generally use sounds to see that the patency of the urethra is all right, but do not find that it is necessary to pass them regularly and for a protracted period after the operation. I have never seen a stricture following the operation.

RESULTS.

I have now operated on 15 cases with the prostatic tractor, and generally by the technic described above. All of these cases are living and well. All can empty their bladders completely and none use the catheter. Incontinence of urine has never been more than a temporary affair, and the perineal fistula has closed in all, except the recent cases. One case, 69 years of age, with

a tremendous prostate, who had led a catheter life for 10 years, is now, 7 weeks after the operation, voiding urine at intervals of 3 hours. Most of my cases being of such recent date, I shall not lengthen this paper by going into details, especially since it is too early to speak of permanent results.

As to the important question of sexual powers, I have determined that the power of erection is already present in some; that ejaculation is apparently normal, and that the semen obtained by ejaculation contains numerous actively motile spermatozoa and the lecithin bodies which are found in normal prostatic secretion. Their presence show that the bridge of prostatic tissue surrounding the ejaculatory ducts, which I have been careful to leave intact, is furnishing a part of the fluid ejaculated. This is possibly of great importance since it has been shown by Fürbringer that, without the mixture of prostatic secretion, the spermatozoa are nonmotile and apparently lifeless. It is possible that only a small amount of prostatic secretion is necessary to vivify the spermatozoa, and that enough is furnished by the tissue which I have left. On the other hand, it may be that the remaining glands have increased in number after the removal of the lateral compression. Although a longer period of time must elapse before the effects of the operation can be thoroughly realized, I feel convinced, from the cases which I have already studied, early though they are, that the sexual powers will be perfectly preserved, and that their ability to procreate will remain unchanged.

I may also add that the instrument which I have called my "prostatic tractor" has transformed, for me, the operation of prostatectomy. Where before it was (with me—perhaps not with others) an operation done somewhat haphazard, depending largely on the sense of touch, and in the dark; now the entire operation is performed in a shallow wound, accurately under visual control, proper regard being paid to the urethra and to the ejaculatory ducts, so that they are preserved to continue their pleasant duties.

A CASE OF AEROGENES CAPSULATUS INFECTION OF THE NECK.*

LOUIS LEROY, B.S., M.D.

Professor of Pathology and Bacteriology, Vanderbilt University.

NASHVILLE, TENN.

The case which I have to report is one of some interest from the rather infrequent occurrence and from the fact that the *Bacillus aerogenes capsulatus* was obtained from the wound six days before death.

W. F.—Age 23, black, male, single, laborer, muscular and vigorous; family history negative. Entered hospital January 27, died Feb. 4, 1903.

Gave history of having had a "sore throat," with considerable swelling of left side of the neck in the region of the tonsil. The symptoms referable to the throat lessened, but the external conditions became worse, developing considerable swelling and pain.

His physician, seeing him for the first time at night, made the diagnosis of erysipelas. Later the diagnosis at the hospital was made of suppurative cellulitis of face and neck. At this time his pulse was 128, respiration 30, temperature 102.

An incision was made, from which a small amount of dark fluid exuded, but no pus. Thorough irrigation every four hours with bichlorid of mercury was instituted without visible result. The inflammatory reaction around the wound was not at all severe, and after the second day the skin below the incision slowly separated from the subcutaneous tissue, until at the fourth day a gangrenous area was present reaching from the ear to the clavicle, and discharging a light sanguineous fluid from an opening at the lower edge. About the fifth day the skin was entirely separated, leaving the muscles beneath clearly exposed. The fibrous tissue rapidly became destroyed, leaving the underlying muscles, vesicles and nerves clearly exposed to view as in the most careful dissection.

The swelling was not extreme, and until the last day no emphysema or crepitation was present, and then only in small amount.

The temperature ranged from 102 to 105, being with difficulty kept below 104 by ice caps and baths.

The pulse varied from 128 on admission to 140 at the time of death. Until within a few hours of his death it was full and strong, despite its rapidity.

The respirations were rapid, varying from 28 to 34 most of the time, although there were times when it dropped as low as 20 to the minute.

The urine showed a progressive diminution in quantity, specific gravity, total solids, percentage and total elimination of urea, chlorid, phosphates and sulphates.

The reaction was acid throughout. Traces of albumin and bile were present for the first two days, but did not appear again.

The microscopic examination was negative in all the daily examinations.

The blood examinations were of some interest, showing a progressive decrease in the number of erythrocytes, percentage of hemoglobin, specific gravity and hemoglobin index.

The leucocytes showed a progressively increasing infectious leucocytosis until twelve hours before death, when an enormous drop in their number apparently heralded the end of the patient's ability to react. Up to this time he had been cheerful, declaring that he would be entirely well in a few days.

The decrease in leucocytes was mostly due to a great diminution in the number of neutrophiles, which fell from 86 per cent. to 40 per cent.—almost even with the small lymphocytes, which in turn showed a reciprocal increase.

The full results of the blood examinations may be seen at a glance from the accompanying table.

No bacilli were observed in smears of the blood during these examinations. The last day, about 12 hours before death, some irregularity in the red cells appeared, a number of poikilocytes and microcytes being observed, but at no time were any nucleated red cells noted.

An examination of the pus was made six days before death. In smears a large number of bacteria were observed, but streptococci seemed to be absent. Other cocci staining by Gram's method were present, and a few large bacilli, which in all probability were *Bacillus aerogenes capsulatus,* but on which I was unable to demonstrate any capsule, either in ordinarily prepared specimens or by the special methods of capsule demonstration. Some of the pus was collected in sterile capillary tubes, and from these aërobic and anaërobic cultures were made within 15 minutes of its collection. The aërobic cultures were made in ordinary agar in Petri dishes in the incubator. The anaërobic cultures were made by the method of Veillon. In this method a number (15 to 20) of large test tubes of glucose agar are melted by immersion in boiling water for an hour in order to expel all the air. They are then allowed to cool to within a degree or two of the point of solidification, when one of the infected capillary tubes is plunged to the bottom of the agar and its contents expelled by blowing. As soon as the agar is inoculated it is solidified at once by plunging it into ice water. The capillary tube is then immersed into each of the series of

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. L. Hektoen, F. B. Wynn and W. S. Hall.

agar tubes blowing gently into it and agitating it at the same time. In this way a number of the tubes will be inoculated, the number of colonies varying from one or two in each tube to a number too great to count. All the tubes are now placed in the incubator until the colonies develop sufficiently to be studied. Cultures obtained in this way developed a large number of colonies in the deeper layers of the tubes, which were subsequently separated into a strict anaërobe and four aërobic organisms. The strict anaërobe was determined to be the *Bacillus aerogenes capsulatus* of Welch, although in the beginning some uncertainty arose from the absence of a capsule and lack of gas generation in the wound. Both of these characteristics were, however, observed in subsequent inoculation experiments. The following biologic characteristics were determined and verified in the work of investigation.

The organism is a strict anaërobe, but will grow in deep layers of glucose agar in Veillon's method. I was

unable to obtain more than a trace of growth by deep stick culture.

In hydrogen, illuminating gas, carbon dioxid and by the pyrogallic acid method growth will result, but best in an atmosphere of hydrogen. Good growths were also obtained under a layer of *Bacillus subtilis*.

The bacillus grows slowly at the room temperature on all media if the oxygen conditions are favorable. They resisted a temperature between 5 and 0 C. for twenty-four hours. The thermal death point was not determined.

When developed in plate cultures in an atmosphere of hydrogen the colonies may reach a size of 1 mm. in diameter in forty-eight hours in the incubator. These colonies are round, convex and smooth. They refract the light strongly and are finely granular when examined under a low magnification. The edges of the colonies are entire. By reflected light the colonies are whitish opalescent. By transmitted light they are a smoky brown. The bacilli are about the size of anthrax, but the ends are usually rounded. They are frequently found singly, usually in pairs or threes, and once a chain of twenty elements was found. In bouillon cultures they appeared to be somewhat shorter than on solid media. They stain easily, but irregularly, by all the common dyes and also by Gram's method. Old colonies show many individuals who do not take Gram's stain, and chains were observed in which alternate cells only remained stained by Gram's method, the intermediate ones being decolorized. The water of condensation, or rather the small amount of water squeezed out of the agar on cooling, contained the most luxuriant growth, despite the fact that it was exposed to the air. This is accounted for, as pointed out by Novy in the case of *Bacillus oedematis maligni II*, by the fact that the oxygen in the water has been displaced by other gases produced by the bacilli deeper in the tube. It might also be noticed that much of the air was previously expelled from this water during the melting of the agar and that the conditions are not favorable for absorption of much oxygen. In all sugar-containing media large amounts of gas were generated, the bubbles beginning to show in six hours, and in twenty-four hours in most cases the agar would be broken in several places and pushed up against the cotton plug. Some gas was produced in media containing no sugar, but in small amount. Gelatin was very slowly liquefied. One series of tubes kept in the incubator in hydrogen for three weeks refused to solidify on being again cooled, while the controls solidified readily.

The organism appeared to be non-motile, and no flagellæ or giant whips were found.

Spores were found once on an old Loeffler's blood serum culture which had been in the incubator in a Novy jar of hydrogen for seven days, and again on a plain agar reimplantation from the blood serum tube. The spores were central and did not cause any increase in the transverse diameter of the cell. All culture media became intensely acid within twelve hours of growth. This was also the case with the tissues of animals which died from inoculation, and in one test made from the secretion from the lesion of the patient. In this case the secretion had collected to the amount of about 1 c.c. in a necrotic pocket between the skin and underlying tissue. This was so intensely acid that I call attention to it as of possible subsequent value as an early diagnostic point. Litmus milk was precipitated and decolorized without being rendered, and a clear fluid left above the coagulum.

In pure culture in intravenous injection about half of the rabbits inoculated died and the bacillus was recovered from the heart's blood and tissues. Dogs were more refractory. When mixed cultures of *Staphylococcus aureus* and *Bacillus aerogenes capsulatus* were given subcutaneously large sloughing areas of necrosis followed in four out of five cases. The last case formed an abscess cavity which discharged pus containing both bacteria through a small fistulous opening, and finally healed completely.

In another series of inoculations in dogs, through cleansing of the necrotic area with hydrogen peroxid, it resulted in recovery.

A rabbit in which 1 c.c. of a bouillon culture had been injected in the ear was killed, as suggested by Welch of

Baltimore, and in twenty-four hours the characteristic swelling occurred. This was allowed to progress at the room temperature for four days, when the distension was enormious. The gas was then collected over water through a canula and found to contain CO_2 hydrogen and a trace of H_2S.

It burned with a very white, bright flame, resembling, although not so intense, the flame of acetylene gas.

I believe that this is the first case reported in which the infection in all probability entered the tissue through the throat and without history of an abrasion or lesion of the epithelium.

DISCUSSION.

Dr. L. Hektoen, Chicago—In connection with this interesting case I would refer to one in which the infection took place through a transfusion puncture of the skin in the submammary region. Spreading emphysema appeared and after death a general infection of the *Bacillus aerogenes capsulatus* was demonstrated.

Dr. Louis Leroy, Nashville, Tenn.—The bichlorid treatment was carried on in this case for a number of days without effect. In the experiments with animals peroxid of hydrogen seemed to stop the process almost within a day. I believe that further observations on the reaction of the pus in such infections will prove of value.

INFECTION OF THE GALL BLADDER AND BILIARY DUCT CONTENTS.*

EDWIN RICKETTS, M.D.
CINCINNATI.

A little more than a decade ago, if a surgeon opened an abdomen for suspected gallstones and did not find them he was most fortunate if the medical finger of derision for diagnostic failure was not pointed at him—gallstones were considered a disease *per se*.

The nomenclature of gallstones, as it has been and is used, is incorrect. It is not important that we should give the anatomy in detail of the liver, and especially of its system of biliary plumbing. A healthy gall bladder should have tonicity and when well filled it should touch the abdominal peritoneum in front, that portion of the liver posteriorly, the duodenum colon, the stomach and pylorus—all of which are in close proximity.

In the healthy subject, the gall bladder can be artificially anastomosed to the stomach, colon and duodenum. Such has been accomplished in neglected cases by no other effort than that of Nature. As the results of infection, we can justly consider such as serious complications, rather than successes. It is important that the family physician appreciates this, along with knowing that the surgeon is competent to do better work, and for this have better results, if he is consulted as to when is the best time for operating.

The simplest procedure of the list suggested for the relief of the infection under consideration, in more than the majority of cases, is cholecystostomy, which consists in opening the abdomen directly over the gall bladder, incising the bladder, cleaning it out and stitching the edges into the small abdominal incision, leaving a temporary sinus for the escape of the secretions of the liver, until it appears certain that that organ has resumed its normal function and has free drainage through the common duct. If a secondary operation is demanded, one can readily and easily reopen the gall bladder that had been purposely attached into the abdominal incision.

In those cases in which the gall bladder has been distended from empyema, it is gratifying to know how they will contract after they have once been drained. Postmortems show clearly the relationship of those organs adhered in closest proximity to the gall bladder and its ducts—for the bile stain present comes from exosmosis. It is claimed that three-fourths of the cases in which gallstones result occur in women. The work of the surgeons does not find that these cases are more frequently found among those of the higher walks of life following sedentary habits. Precipitation, or the result of bile infection, can give a solitary calculus or hundreds of calculi; numbers do not add to the gravity of any case. The germ theory has been well established. The typhoid and colon bacillus are recognized as the greater microbic elements to be dreaded; more especially the colon bacillus.

Experiment has demonstrated that aseptic foreign bodies within the gall bladder, floating in healthy bile, are not exciters of inflammation. It has been further demonstrated that the gall bladder and its contents can be infected by the typhoid and colon bacillus, necessitating a cholecystotomy, and the cystic duct remain free from infection and still perform its function.

It is in this class of cases that rupture of the gall bladder occurs. With the inflammation extending to the cystic and common duct, we can have the biliary colic attacks that so often have been credited to the passage of calculi through the common duct. We have an illustration in the attacks of appendicular colic in which there is no foreign body present. In those distended gall bladders that come from such a redundancy of tissue, there is residual bile, which of its weight causes flexion of the gall bladder at the cystic end.

The cystic and common duct may be healthy and yet fail to carry off these gall-bladder contents. This stagnant bile can easily become infected by the microbes passing through the walls of the colon, duodenum and portal vein through the gall-bladder walls, attacking the bile. This explains how a serious gall-bladder infection can be present while the cystic and common ducts remain patent, or partially so. The patient may succumb to septicemia before Nature can effect an anastomosis of the gall bladder to the duodenum or colon. The adhesions to the proximal tissues are numerous and make formidable the doing of any subsequent operation on the gall bladder or its ducts, as in trying to relieve the distressing symptoms that so often arise. The residual bile results from the redundant tissue of the anteflexed gall bladder, which is lacking in contractile power. The contents are especially liable to infection.

We find many contracted and flexed gall bladders held firm in a bed of adhesions, causing pain and discomfort to the patient. Freeing these adhesions and correcting the flexion often effects a cure. The precipitation of the salts of infected bile can be found in the biliary ducts and in the hepatic cells.

It is not the over-extended gall bladder, and the one which may be readily felt through the thin abdominal wall, that is so badly in need of the prompter surgical intervention, as much as it is the infected and tense gall bladder with localized pain with loss of strength, a low grade of fever, accelerated pulse, and with more or less sallowness of the skin. The localized tenderness is brought out by a deep, firm pressure over the gall bladder by one of the middle fingers, causing a sickening pain. We have pinhole ruptures occurring in the gall

bladder, cystic and common duct, with the possibility of hepatic and perihepatic abscesses to follow.

Jaundice is a serious complication in those cases that are to undergo a surgical operation. Bile reabsorbed is a formidable poison, acting, as it does on the heart and kidneys. It is much more poisonous than urine. Fatal secondary hemorrhage in cholemic subjects has resulted fatally following a simple abdominal section. In these cases midoperative hemorrhages are not always readily controlled. Rupture of the gall bladder has followed an attack of vomiting. Roth, Schroeder and Schloth made 10,866 necropsies, finding biliary fistulæ forty-three times. Courvoisier reports 539 fistulas; 184 between the bile ducts and the abdominal wall, 108 between bile ducts and duodenum, ninety-three between the gall bladder and the duodenum, twelve between the gall bladder and the stomach, fifty between the bile ducts and the colon, and forty between the gall bladder and the colon. These reports lead us to think that biliary fistulas are not so common as the profession in general have been led to suppose.

The sudden escape of a portion of the contents of an empyemic gall bladder means rapid infection of the peritoneum.

Dr. Barker, Bellvue, Ky., tells of a case in which the tip of the gall bladder was shot away from a healthy subject. Bile poured out freely through the abdominal wound, and with it soon came one large gallstone. The wound was packed and kept clean, and the patient recovered.

In infected gall bladders it is well to make the incision directly over the gall bladder, and after failing to dislodge the stone downward and into the duodenum by the probe, or upward and into the gall bladder by upward pressure of the finger, it is better to incise the duodenum, exposing the common duct opening into the same and, after careful dilating, pass a probe into and through the common duct; pushing, if possible, the calculi up into the cystic duct, or, better, into the gall bladder for extraction from above through the incision by means of the alligator forceps. Any calculi located in the cystic or common duct acting as a ball valve, so graphically described by the late Christian Fenger, can be drawn out through the incised gall bladder by means of the forceps.

With early diagnosis of infection of the contents of the gall bladder—in which the tenderness over the same does not disappear along with the fever, accelerated pulse, lethargy, loss of flesh and strength—a cholecystostomy will relieve these patients better and more satisfactorily than efforts at medication can possibly do.

The early diagnosis of biliary infection is not difficult. With a careful consideration of the principles laid down it is as easy as that of appendicitis. With an early diagnosis these cholecystostomies may be successfully performed under local anesthesia. If difficult complications should arise, general anesthesia may be resorted to in order to complete the operation.

The laity must understand, through the family physician, that it is not a harmless disease, and that this optimistic view that is held is most dangerous to many valuable lives. Those cases that are said to recover from medication are so rare, comparatively, as to be unfortunate for those cases that come after. The liver is the largest secreting organ within the body; its secretions are the most abused in health, the most neglected in disease.

DISCUSSION.

Dr. L. H. Dunning, Indianapolis—I think we all agree that empyema of the gall bladder frequently results in speedy death if drainage is not obtained. But it is a question how far the operation should be carried and how much should be done in severe cases associated with stone in the common duct. These patients are poor subjects for surgical work, and in the majority of instances, if there is an impacted stone in the common duct, or dilated portion of the duct, there is intermittent jaundice; so that we have added to the dangers of shock those of septicemia and secondary hemorrhage. These dangers must be taken into account in every gall-bladder operation. From the picture the essayist has drawn I would advocate in all instances the attempt to remove the stone from the common duct. But if we have a patient greatly exhausted from septicemia and very much jaundiced, either intermittent or permanent, with a stone in the common duct, we will do well in many instances if we content ourselves by draining the gall bladder, because 75 to 80 per cent. of our patients will die if we go beyond that simple procedure. As to cases in which we feel justified in doing something, where there is a stone in the common duct, I would not like to accept in an unqualified manner the technic given by the essayist. I would hesitate to add to the danger of exhaustion the danger of opening the duodenum. I do not believe that we will often find this necessary. If we can not move the stone upward or downward by manipulation it will, in the majority of instances, be better to open the common duct. If the stone is in the middle of the duct or near the duodenum we will have better results if we incise the common duct and remove the stone, which can be done very quickly, and then resort to the method of Kerr—drainage of the hepatic duct by insertion of a tube. These cases have a mortality somewhere between 75 and 85 per cent. even in the hands of such masters as Kerr and Robson. I have found that by simply draining the gall bladder the signs of septicemia pass away, the patient partially regains his health, and the mortality is then only about 10 per cent. Therefore, in these severe cases I advocate two operations: 1. Opening and draining the gall bladder. 2. After the patient has regained health reopening the abdomen and removing the stone from the common duct.

Dr. C. V. Thienhaus, Milwaukee, Wis.—I would like to defend the duodenal route in impaction of gallstones in the common duct. The transduodenal route does not come into question when the stone lies in the upper or in the middle portion of this duct, but it does when the stone is impacted near the papilla or in the so-called retroduodenal portion of the common duct. I do not see any reason, as I have pointed out,[1] why, when a stone protrudes at the papilla and is almost in the duodenum, or when it lies impacted in the retroduodenal portion of the common duct, where it is very difficult to reach from the middle portion, we should not for these cases use the natural and more easily to be performed transduodenal route. I operated on one case in this manner in which a stone was so firmly impacted in the retroduodenal portion that even after opening the duodenum and making a large incision into its posterior wall, it was difficult to dig it out of its diverticulum. After removing the impacted stone three other stones lying higher up in the common duct could easily be stripped down into the duodenum and removed. The woman is perfectly well now and gained 67 pounds since the operation, which was performed 15 months ago. For this class of cases I can heartily recommend McBurney's transduodenal route.

Dr. S. S. Halderman, Portsmouth, Ohio—In the early history it is not always possible to make a diagnosis. The pain is not pathognomonic. I have been very much in doubt at times, owing to the age of the patient, whether there was a malignant trouble or a benign disease of the gall bladder. In cases of contracted gall bladder in which there are but one or two stones, and in which there has been more or less irritation going on for some time without severe attacks of such hepatic colic as accompanies the passage of smaller stones through the duct, I have come to the conclusion that an ex-

1. "The Transduodenal Route, etc.," Annals of Surgery, December, 1902.

ploratory incision is demanded for the safety of the patient. When there is a distended gall bladder in cancer of the pylorus pressing on the gall ducts and obstructing that organ, by draining the gall bladder one can make a patient very comfortable, and, in fact, prolong his life. In a recent case I made an incision and found malignant disease. I drained the gall bladder and the patient lived three or four months with comfort. She had been taking very large doses of opium for the terrible pain, but after the operation she abandoned it.

Dr. H. O. Marcy, Boston—The question of vital importance is how and when to make the diagnosis, rather than the question of operative details. The most lamentable feature of the whole matter is the failure of the general practitioner to recognize these conditions early and bring them to operative procedure early. If we could make an emphasis in this direction we would do a much greater service to the public than by confining ourselves to the technic of the operation. It is true that we ourselves were blunderers. I was the first to remove stone from the common duct, and yet that was almost an accidental condition. But the unfortunate thing was that the patient had been allowed to go on to the risk of life before operation. Let the general practitioner study his cases of obscure gall-bladder disease and not think that when he has biliary obstruction and an extreme case of jaundice that that is the time to consult.

Dr. A. Palmer Dudley, New York—In cases of empyema of the gall bladder, or of systemic infection, I aspirate the gall bladder, having first grasped it with two pairs of fine forceps so that it can not collapse and get beyond my reach. After aspirating the gall bladder, before opening it, we are able to make a more perfect diagnosis of the condition existing in the bladder. Then I refill that gall bladder with a 1-500 formalin solution. I have been using formalin in infection for a long time, and have found it to be a thorough germicide. One can wash out the bladder and aspirate as many times as one pleases until one has a thoroughly aseptic bladder before one opens it to remove the stones. In cases such as Dr. Ricketts described I agree with him. I believe it safer to fasten that bladder up and drain it than to do a radical operation. In many cases a radical operation may seem better for the patient, but with the patient thoroughly saturated with bile, the vessels engorged with bile, there is no contractile power in them. There is no power to form a good plug in such a vessel and the danger of hemorrhage is great.

Dr. Edwin Ricketts—The emergencies bother us more than anything else in operating. It has been well said that the essential treatment of cases in which the stone is in the common duct is along the line of prophylaxis, a procedure which I advocate, for then we will not have the stone in the common duct. One point I want to impress is that there is never a stone in the common duct, but that there have been symptoms long before that that the family physician should recognize and treat by prophylaxis. That prophylaxis is draining of the gall bladder. Washing out the gall bladder with formalin is a good suggestion. The greater number of cases of malignancy occur after the age of 50, but there are quite a few cases of infected gall bladders at 30 and some before 20, and wherever you find an infection I do not see why the general rule of surgery should be reversed and that is, turn out the infection. And yet the gall bladder is the last organ from which the suggestion for drainage should come. Dr. Goelet knows of the pressure on the kidney by a damming back of the urine, causing a hydronephrosis. Is there a surgeon who would hesitate to remove a stone in the urinary bladder, no matter how small? We are beginning to better understand the importance of infection. Delay under these circumstances has caused more deaths than all the surgical experimentation on the bile ducts. Infection of the gall bladder is a bad thing. These are unpromising cases; bad cases to work on. It is far better to handle these cases in the line of prevention than to operate when the gall bladder is full of pus. The importance of not delaying has been demonstrated time and again, and it has been so impressed on me that I now do this work as I outlined it in my paper, and I fear no criticism.

SARCOMATOUS TRANSFORMATION OF MYOMATA.*

THOMAS S. CULLEN, M.D.
BALTIMORE.

This report includes several cases of myomata where sarcomatous changes have occurred. From the num-

Fig. 1.—Probable sarcomatous transformation of a myoma, also discrete myomatous or sarcomatous nodules in the same uterus. At g is a typical submucous myoma. At c one of the sarcomatous nodules, while at d is a transition from the myomatous muscle into sarcoma. Fig. 2 is from the same case.

Fig. 2.—Association of myoma and sarcoma in the same uterus. The myomatous nodules are very easily differentiated from the homogeneous sarcomatous ones.

ber of cases recorded it is evident that the disease is more frequent than heretofore suspected. The sarcoma usually develops in one of several myomata and may

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. A. Palmer Dudley, H. P. Newman and J. H. Carstens.

be situated in a subperitoneal interstitial or submucous nodule. Until recently it was supposed to be confined chiefly to submucous myomata.

Fig. 3.—Sarcoma of the anterior uterine wall. The pale framework c seems to be myomatous in character.

Fig. 4.—Sarcomatous transformation of bundles of myomatous tissue.

The gross changes are characteristic, the firm cross-grained myomatous tissue being replaced by a homogeneous yellowish white growth devoid of a fibrous arrangement and closely resembling raw pork. Degenerations in the sarcomatous tissue are frequent.

Histologically these growths are found to develop from two sources:

1. The connective tissue.
2. The uterine muscle.

Those of connective tissue origin may consist:

(*a*) Of spindle-shaped cells.

(*b*) Of round cells.

In those derived from the muscle a direct transition from the muscle fibers into the sarcomatous ones can be followed. Several such cases have been noted at the Johns Hopkins Hospital.

The clinical history is rather significant: A myomatous uterus has lain comparatively dormant for several years and the patient comes with a history of rapid uterine enlargement during the last few months. If the myoma has been submucous portions have from time to time been expelled "recurrent fibroid," and there is a free offensive discharge. The patient soon becomes cachectic.

The operative significance of recent laboratory investigation may be thus summarized:

1. Whenever sarcoma or carcinoma may coexist with myoma panhysterectomy is imperative—not amputation through the cervix.

2. Bisection of the uterus is contraindicated where there is a possibility of a malignant growth developing in or associated with the myomatous uterus.

3. In every case of hysteromyomectomy it will be advisable to have an assistant open the uterus immediately on its removal to determine if carcinoma of the body exists and to find out whether the myoma has become sarcomatous. If malignancy is detected the cervix can thus be removed without delay.

DISCUSSION.

DR. JOHN G. CLARK, Philadelphia—All scientific research should in some way lead to improvement in the practical treatment of patients, for our vocation as physicians and surgeons is to practice the healing art. From a purely clinical standpoint the work which has been presented by Dr. Cullen may appear to be clearly of scientific and not of practical interest, and yet, if his observations are applied to the clinical care of cases of fibromyomata of the uterus, it at once has a very important bearing. Noble concludes, that while fibroid tumors are benign, nevertheless the ultimate results and complications arising from them are such that it is seldom, if ever, justifiable to withhold operative interference. Practically applied, it seems to me that Dr. Cullen's work is an argument for Dr. Noble's questionable position, for he has shown that fibroid tumors which hitherto we should have taken as simple benign growths may actually already have undergone sarcomatous transformation. About 2 per cent. of all fibroid tumors are associated sooner or later with a malignant process, e. g., in some instances, cancer of the endometrium. This I have recently encountered in my clinic at the University Hospital in two cases, in which no suspicion of malignancy had been entertained. Williams, Pick and Cullen have shown that the muscle or fibrous tissue cells may actually be transformed directly from a benign to a malignant process. In contradistinction to this, cancer may be looked on as simply an engrafted process, which invades and destroys, but is never a pathologic transformation of a connective tissue to an epithelial cell. In hysterectomy for fibromyomatous tumors, my rule is invariably to leave the ovaries, if possible, and a portion of the uterus with its endometrium, in order to perpetuate the menstrual function to its natural cessation. The retention of only one-third of the original volume of the uterus will maintain menstruation. If this transformation observed by Dr. Cullen occurs with any

great frequency the latter policy may be questioned, for we may be leaving behind a portion of a malignant growth. I judge, however, from his paper that this transformation is not frequent, and therefore, especially in young women, the fear of its recurrence should not materially influence us in discarding the conservative policy. While some distinguished surgeons are inclined to deny the possibility of auto-implantation, I am convinced that it is possible to carry cancer cells from the field of operation into healthy tissue where cancer will recur. I wish to ask Dr. Cullen how often these malignant transformations of fibroids occur and how far his observations justify the physician in favoring the early removal of these clinically benign tumors with a view to preventing the complication.

Dr. L. H. Dunning, Indianapolis—I would like to have Dr. Cullen consider the influence of these findings on our technic in myomectomy. I also wish to ask whether or not he has collected statistics on the recurrence of these growths after complete and after partial removal of the uterus.

Dr. C. O. Thienhaus, Milwaukee—Does Dr. Cullen conconsider the presence of giant cells and myoclasts in fibroids a sufficient proof of malignancy? Saenger stated that all fibroids containing giant cells and myoclasts had to be classified as showing sarcomatous degeneration. Concerning Dr. Dunning's question, Martin found sarcomatous degeneration 6 times in 205 cases of fibroids, but this percentage is an exception and extremely high, in my opinion. Landau collected from the literature 10 cases in which following retroperitoneal hysteromyomectomy later on a malignant growth developed in the cervix.

Dr. C. L. Bonifield, Cincinnati—About eighteen months ago a patient came under my care who had had an ectopic gestation that went to full term and who had had a missed labor fourteen years before I saw her. She developed an immense fibroid, larger than my head, which was undergoing sarcomatous degeneration at the time of the operation. I removed the uterus and the tumor and the ectopic gestation, but unfortunately she died a few weeks afterward from a recurrence of the sarcoma.

Dr. T. S. Cullen—It is impossible for me at this moment to tell the exact percentage of myoma cases in which sarcomatous degeneration takes place, but from 1.5 to 2 per cent. show changes definitely sarcomatous in character or strongly suggestive of it. Carcinoma of the body of the uterus is relatively common where uterine myomata exist. Taking all myoma cases we have at least 2 per cent. in which a malignant growth of some character is present. In hysteromyomectomy in favorable cases where there are not many adhesions the mortality will not be higher than this. I fully agree with those who advocate early operation in nearly all cases. Operate before adhesions have formed. I do not wish to deprecate bisection of the uterus. It is a most admirable operation where the uterus is wedged in the pelvis, thus preventing us from reaching the uterine vessels. If we bisect the organ the myoma can be rolled out, more space is thus obtained and the vessels are more easily controlled. But in these cases we must remember the possibility of sarcomatous degeneration of the myoma. We must, however, run the risk of cutting into the sarcomatous myoma as in some of the cases the myoma is so wedged in the pelvis that its removal would be impossible by any other procedure. Recurrences in cases where sarcomatous degeneration has taken place are certainly appalling. In some of the cases where bisection of the uterus was done the patients died of infection in a few days. I have a record of one case where within six weeks after hysterectomy the pelvis was filled with a sarcomatous growth. In one of our cases where temporary recovery took place Dr. Osler saw her six months afterward and there were metastases in one lung and in the mediastinal glands. She soon died. From the histologic standpoint it is most interesting to follow the sarcomatous changes in myomata, but we sometimes have specimens where it is impossible to say absolutely whether a given area is really sarcomatous or merely a suspicious but benign growth. One can not interpret the changes in the muscle cells with the same degree of precision as is possible when considering cell changes in the endometrium. From a systematic examination of the uterine mucosa we have found in nearly all cases where the tubes and ovaries are normal that it is unaltered. The changes that do occur in the endometrium are dependent almost entirely on the situation of the growth. If it be partially submucous the mucous membrane over its most prominent part will be thinned out more and more until eventually it is represented by nothing but a layer of epithelium. This, after a time, is flattened and disappears. In the depressions between the myomata there is often slight gland hypertrophy or polypi develop. Knowing that the endometrial changes are almost entirely mechanical in nature where normal tubes and ovaries exist, we can open up the uterine cavity in myomectomy cases when necessary, there being little danger of infection. On the other hand, it is rarely, if ever, advisable to do a myomectomy where the appendages are adherent. Several years ago I operated on a patient suffering from adherent tubes and a myoma in the posterior uterine wall. There was no evidence whatever of any recent infection. I made artificial extremities for both tubes and then did a myomectomy. Shortly afterward the patient's temperature rose and she developed definite signs of sepsis. Although we reopened the abdomen and drained thoroughly she died of sepsis a month afterward. In this case some old infection evidently lurked in the tubes and readily extended to the uterine walls at the site of the myoma enucleation. I would strongly advise against myomectomy in any case where the appendages are adherent.

A CASE OF ACUTE DISSEMINATED ENCEPHALOMYELITIS,

PRESENTING THE CLINICAL PICTURE OF MULTIPLE SCLEROSIS.

JOSEPH L. MILLER, M.D.
CHICAGO.

Acute disseminated encephalomyelitis manifests itself in one of two clinical types, viz.: As an acute ataxia or acute paraplegia. The ataxia type is often described as acute ataxia, or better, acute central ataxia, the latter term serving to differentiate it from the ataxia resulting from peripheral nerve changes.

Eisenman in 1863 described a case of post-typhoid ataxia as a result of myelitis. Leyden in 1868 reported a case following trauma. Westphal in 1872 reported several cases following variola and typhoid, and was the first to verify his diagnosis by autopsy. Ebstein at the same time reported a case of speech and co-ordination disturbance following typhoid, and eight years later reported the autopsy findings on the same case. Pollard in 1872, under the title, "Case of Locomotor Ataxia, Beginning Suddenly and Disappearing Under Treatment," described what was probably a case of myelitis. During the past thirty years numerous cases have been reported which, with the pathologic investigation, have verified the findings of the earlier writers.

NARRATION OF CASE.

This patient entered Cook County Hospital in July, 1902, in the service of Dr. Dolamore, through whose courtesy I am permitted to report the case.

History.—Patient was 47 years old, laborer. Family history was negative. He had been a moderate drinker during the past ten years; previous to that he drank excessively; he chews and smokes tobacco. He had syphilis twenty years ago and was treated at irregular intervals for several years. Six years ago, as the result of a trauma, he sustained a fracture of the right femur. Three years ago the patient was in Cook County Hospital with croupous pneumonia; during the course of the disease he suddenly developed an aphasia, which was only complete for a few days, rapidly improving. Whether there was an involvement of the legs at the same time the pa-

tient does not know and no record of it was made at the time. A few days later the patient made his first attempt to walk, and found that he staggered like a drunken man. Slight disturbance of speech has persisted since, particularly manifested in a slowness and monotone with inability to make himself understood when excited. The difficulty in walking varies with periods of marked improvement followed by relapses. There has never been any bladder or rectal symptoms. Sexual power is lessened, but eyesight is unimpaired. There is no gastric disturbance. His memory is good. He is more emotional during the past three years.

Examination.—The patient is well nourished and his color is good. The feet are widely separated in walking; toes abducted, heels striking the floor first. Muscular strength in all groups of muscles of both upper and lower extremities is good. There is no marked atrophy. Touch, pain and temperature sense are normal. There is marked swaying when the patient stands with his feet together, which is increased by his closing his eyes. There is no ataxia of the legs when lying down and very slight inco-ordination of the arms. There is slight tremor of the hands when at rest, increased by intended movement; very marked intention tremor in legs; none of head. The pupils are equal, reacting to light and accommodation, with marked horizontal nystagmus, no optic atrophy. Skin reflexes are present; knee jerk is slightly under normal. The patient speaks slowly and in a monotone, no distinct scanning. The hearing in the left ear is slightly impaired.

ETIOLOGY.

The vast majority of the cases of disseminated myelitis develop during or following the acute infectious diseases, especially variola and typhoid, less frequently whooping cough, erysipelas, dysentery, measles, influenza, malaria, tuberculosis and gonorrhea. Several cases are reported following exposure to wet, cold or severe fatigue. Leyden reports a case two weeks after fracture of the arm, Taylor after injury received in alighting from a train. A definite etiologic factor was not apparent in many cases.

Experimentally, Babinski has produced both transverse and disseminated myelitis by injection of *Bacillus pyocyaneus,* Roux and Yersin with *B. diphtheriæ,* Rogers with streptococcus. Eisenlohr found staphylococci in the cord in a case following typhoid. Banir found staphylococci following gonorrhea.

PATHOLOGY.

Westphal examined two cases of the paraplegic type, and found multiple areas of necrosis in the cord. Ebstein's case showed gray foci in the cord and medulla. Examinations of recent cases show perivascular inflammation in the cord, medulla, pons and cerebrum—in the latter in both gray and white matter. The nerve fibers are destroyed, the neuroglia increased.

SYMPTOMOLOGY.

Clinically, the disease manifests itself as an acute ataxia or paraplegia. The characteristic symptoms of the ataxia form given by Westphal were: 1, Slow or scanning speech; 2, ataxia with normal or slightly lessened muscular strength; 3, no sensory disturbances; 4, often psychic disturbances.

The ataxia is often more marked in the upper extremities, or it may be present in the form of a hemi-ataxia. Ebstein's patient could move his legs in bed without difficulty, but was unable to walk. Unconsciousness may mark the onset, the ataxia only appearing later as in Lenhartz's case; anesthesia and sphincter paralysis marked the onset, the ataxia appearing two weeks later. Intention tremor of the head and extremities is usually present. Nystagmus is an infrequent symptom. Speech disturbances are almost always present, varying from complete aphasia to slight slowing or monotone. Slight if any superficial or deep sensory disturbances are present. In Lenhartz's case the anesthesia present at the onset disappeared in two weeks. Sphincters were, as a rule, intact. Ptosis was present in Pollard's case. Optic neuritis has been occasionally noted. Skin reflexes usually unchanged. Tendon reflexes often exaggerated.

The paraplegic type is characterized by a flaccid paralysis, with loss of knee jerk, sphincter involvement and often sensory and trophic disturbances.

The course is: 1, Early complete recovery; 2, partial recovery, with perhaps only one symptom remaining, as the speech disturbance; 3, periods of improvement with relapses, the condition being progressive. Ebstein's case showed slight improvement in the beginning, followed by gradual progression, the ataxia reaching such a grade that the patient was confined to his bed during the last two years. Westphal believed that many cases reported as recovered would later relapse. Early fatal termination is unusual.

RELATION TO MULTIPLE SCLEROSIS.

The clinical picture in many of these cases, including the writer's, is one of multiple sclerosis. Leyden formerly maintained that the absence of progression differentiated it from this condition; this has not, however been supported by clinical facts, as in Ebstein's case quoted above. Instead of an acute process with healing and permanent defects, the acute onset would appear to mark the beginning of a chronic process, which may become latent, but more frequently tends to advance. Pathologists are agreed that the anatomic findings may be identical with those of multiple sclerosis. The clinical symptoms complete the picture, and it would be preferable, as is insisted on by many writers, to consider these cases of multiple sclerosis with acute onset.

TREATMENT.

In the early stages, rest in bed, with special attention to the skin to prevent bed sores, is essential. Cold may be applied along the spine, without, however, much hope of benefit. Later, the use of massage and electricity is of value. The systematic exercises employed in tabes are of value in lessening the ataxia. Freedom from exposure to cold and over-fatigue may prevent acute exacerbation. The long list of drugs which are reported as curative is evidence that spontaneous recovery, or at least improvement, is not unusual.

100 State Street.

DRAINAGE, SEWERAGE AND WATER SUPPLY OF NEW ORLEANS.*

GEORGE G. EARL.

General Superintendent of the Sewage and Water Board.

NEW ORLEANS.

In undertaking to give you a brief account of what has been done, or is contemplated, in the direction of the draining and sewering of New Orleans, as well as in the matter of a water supply for her 300,000 thirsty citizens, I understand that I am undertaking a task which will require a most direct method of treatment, to be kept within bounds as to time, and will, therefore, without circumlocution or delay plunge at once into my subject.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Hygiene and Sanitary Science, and approved for publication by the Executive Committee: Drs. S. Fulton, Seneca Egbert and H. M. Bracken.

A map of southern Louisiana will show that New Orleans was begotten, geologically, geographically and commercially by the Mississippi river, which, beside being the Father of Waters, and of New Orleans, is the father as well of a very large area of assorted swamps and fertile alluvial lands known as the Mississippi delta.

Just to the north of New Orleans lies Lake Pontchartrain, which is twenty-five miles wide and forty miles long. North of Lake Pontchartrain are nearly level plains covered by pine forests which rise very gradually as one leaves the lake shore. These are not of any recent alluvial formation, and several of the small rivers draining this area command the only local water sheds which New Orleans could consider as possible sources for a water supply which would yield a soft water, free from the great amount of silt which the Mississippi river always carries. I will have occasion later to speak a little more fully in regard to them.

All the land remaining in southeast Louisiana, east, south and for eighty miles west from New Orleans, is the creation of the Mississippi river. A hundred miles of original gulf front has been advanced eighty miles into the gulf by its deposits. For centuries the river has been scouring half of the continent for material to this end, and no year has passed that it did not, in annual overflows, contribute vast accumulations of silt. Through many outlets, all with shifting channels, it poured its muddy waters, cutting here and building there, according to its whim, but building always until every outlet was in truth a river on a hill. No natural drainage anywhere in the area finds its way into the Mississippi river, but rather seeks the gulf through the swamps behind, the surface of the river, even at low water, being about level with the low lands lying but a short distance from its banks, and at high water so far above even the natural banks which its waters have built, that in order to inhabit and cultivate their fertile fields and protect them from further overflow, artificial embankments, or levees, ranging from a few feet high at the lower end of the river to as much as twenty-five feet in places higher up, have had to be constructed. The lands thus reclaimed are immensely productive and repay many times the cost of their reclamation, and even compensate, in the long run, for the occasional disasters which follow broken levees and the inundation of large areas with the consequent loss of crops and great damage to existing improvements.

These lands, for an indefinite depth, are river silt; a stone even as large as a pea could not be found in a whole parish. They vary from a heavy, sticky, plastic clay to sand of various grades, the clay predominating; while at gulf level the lands have often been covered by vast cypress forests, many of which still remain, while others have vanished and been covered by silt from subsequent overflows, resulting in strata of stumps (some of which excavations reveal in a distressingly good state of preservation) and in other strata of rootlets and vegetable fiber very nearly resembling peat, but often mixed with clay. All of this soil is saturated, though so close grained as to part with its water most slowly and reluctantly. At New Orleans a hole, say four feet in diameter and two or three feet deep, will usually show water at its bottom, but on sinking the hole deeper the water will be taken out with the excavation and without pumping, and it will require often several days before enough water will seep into the hole to fill it to the level at which water originally stood.

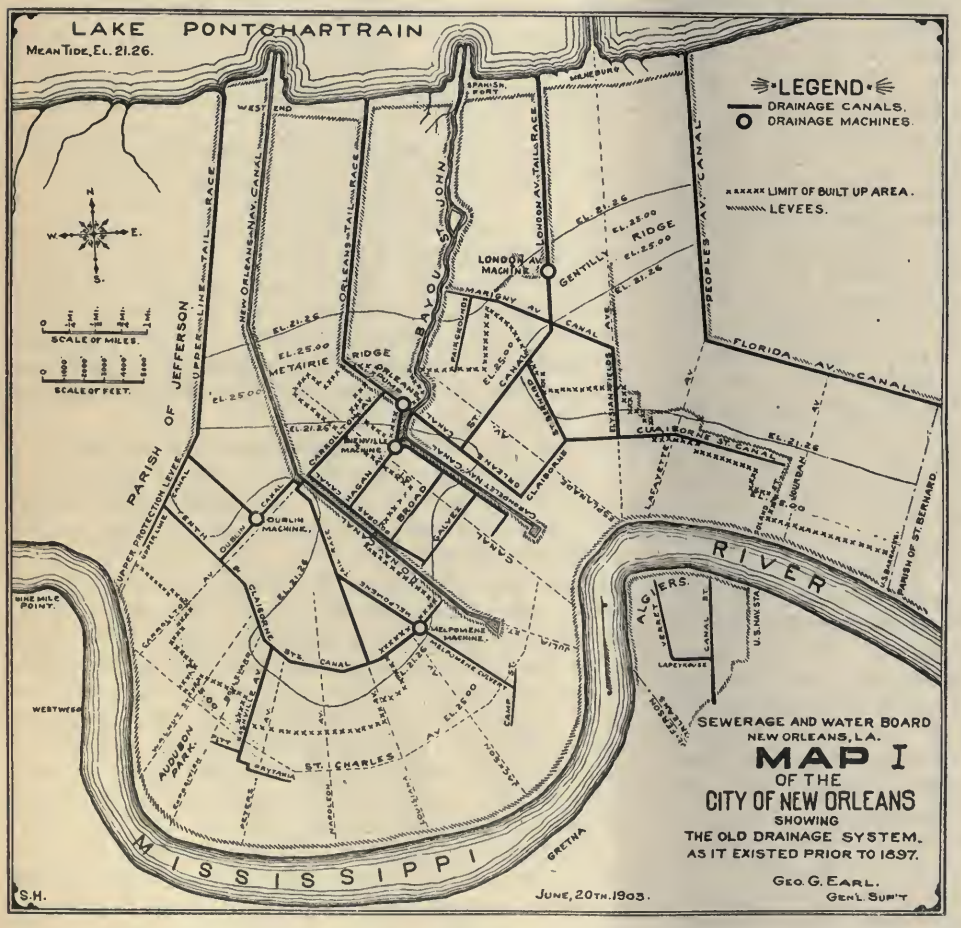
In making excavations no picking to loosen the earth is required; a shovel enters easily, but in the predominating clay it takes a strong man to raise a shovelful, and to cast the dirt from the shovel is usually impossible as it sticks with remarkable tenacity.

Such a saturated, plastic soil as just described has only a very limited bearing power; overload it and down goes your structure. It partakes, in a limited sense, of the nature of a thick fluid, transmitting pressures and vibrations somewhat as a fluid transmits them, and making foundations for heavy structures as well as excavations of great depth both difficult and expensive.

Your attention is now invited to a map (No. 1) of New Orleans (the city limits really cover considerably more territory than is shown, but the remainder need not be considered).

Within the area shown by this map there are some 900 miles of streets. Over 600 miles of these are really open, and about 400 miles are in the well-built or rapidly-building area. The total area covered by the map and within the city limits is about 20,000 acres, or thirty-one square miles, sufficient easily to accommodate 1,200,000 people. The top of the map is north. Near the bottom of the map is the Mississippi river, which nearly boxes the compass in passing New Orleans, running in every direction save west, and rendering the question of "where is north" hopeless to strangers and difficult to the dwellers on its banks. At low stages of its waters the river surface rises and falls with the irregular gulf tides, and despite the fact that its minimum discharge is seldom less than 200,000 cubic feet per second, and its distance to the gulf about 100 miles, we often find its surface at New Orleans practically at gulf level.

At extreme high water the minimum discharge is multiplied by ten, the velocity is enormous, and the surface of the seething yellow waters stands twenty feet above gulf level, and as much above over half of the area shown on this map.



The northern boundary of the city is Lake Pontchartrain, which is really a shallow arm of the Gulf of Mexico, slightly brackish and affected by gulf tides which have a fluctuation of only a few inches daily, but under the influence of the winds have an extreme range of nearly six feet, from two feet below to four feet above mean gulf level. Lake Pontchartrain is a beautiful sheet of water. Several pleasure resorts lie on its shore within the city limits, and the navigation of its waters for both business and pleasure forms an important part of the life of New Orleans. Leading from the lake into the city are two navigation canals in which, also, the water stands at gulf level; at high lake tides their water surface is as much as five feet above portions of the city through which they pass, levees only preventing overflow.

Between the river and the lake, and about two miles back from the lake shore, is a narrow area, one-fourth of a mile wide, crossing the city, marked Metairie ridge and Gentilly ridge. This ridge is the handiwork of an old bayou which at one time traversed it, and which, by the overflow of, and deposit from, its silt-laden waters, erected this barrier, just high enough to prevent high lake tides from flooding the area to the south of it.

This ridge and a strip averaging about a mile in width on the immediate bank of the river, make up the only area which really has a natural drainage. It covers 5,000 acres, or about eight square miles. Even this area averages only about nine feet below mean gulf level and ten feet below the high-water mark of the river. On either side of Metairie ridge, sloping away for

a short distance, the land is between mean and high gulf level (as far as the fine black lines on the map marked "elevation, 21.26"). To the north of this the land lies at or below mean gulf level, and is mostly unreclaimed swamp, as marked on Map IV. This area is about 5,000 acres, and for the present, in sewerage and water calculations, it can be ignored.

South of Metairie ridge we have nearly 15,000 acres, or twenty-three square miles of area; of this, 6,000 acres, or about nine square miles, lie at or slightly below mean gulf level. Under natural conditions, this would be always flooded. Four thousand acres, or about six square miles, lie above mean lake level but below the high-water mark in the lake, and this would also, under natural conditions, be flooded whenever an extremely high-water occurred in the lake.

A line of crosses defines the rear boundary of what may be called the present built-up area of the city. Between this line of crosses and the Mississippi river practically the whole present population of the city have their habitations. The area of this populated territory is nearly thirteen square miles; it has 400 miles of streets and a population of over 300,000 people.

Considering the conditions as just outlined you will not be surprised to note that the high zone nearest to the river bank is that which has attracted nearly all of the population, and that the remainder is either on the intermediate, or else concentrated within lower areas in which artificial drainage has been most effective. The heavy black lines on this map show the only main drainage arteries which existed prior to 1892, and the black circles the pumping stations which had to lift all of the drainage which came to them from their river, or low side, into leveed outfall canals, sufficiently above lake level, on their lake side, to cause a discharge into the lake. These pumping stations were nothing more nor less than great undershot water wheels which were worked backward by steam engines, and paddled the water which came to them forward and upward.

The canals from which and into which these wheels pumped were practically level, shallow earth canals, and the vertical distance through which the wheels could lift was very small. The capacity of the wheels was insignificant in proportion to the vast amount of drainage which they had to handle, and the canal system, as you will notice, was confined to the low areas, the natural slope of the ground from the river to these low areas being depended on to deliver storm water to the canals through open gutters on every street leading from the river directly back to them.

So far as the populated area of the city was concerned, this system of storm water drainage was purely a surface system with open gutters, broad, flat and deep, on every street perpendicular to the river and crossing every intersecting street by surface culverts. Into these gutters liquid household wastes had to be discharged, and in dry weather such wastes were insufficient to cause a current, so that what was practically sewage (since it contained every element of sewage save water closet discharge) lined every street in stagnant pools. With great rainfalls, which are frequent in New Orleans, the waters from the upper end of each street, moving down from the steeper grades along the river front, soon overtook that which was collected where the slope begins to flatten out and the accumulated flow would speedily fill each street from curb to curb, and often from property line to property line; or even worse, being checked at each intersecting street by the necessity for passing through culverts with greatly restricted areas. It would often require several hours for even that portion of the city which really has sufficient elevation for natural drainage to be freed from overflow, while the low areas, as indicated by the vertical lines on the map, being altogether dependent on the pumping stations, would have to wait as many days before the drainage wheels could reduce the general water level to a point that would expose their natural surface and bring the water within the banks of the canals, as shown on the map.

It might be of interest to note that on the day when the people of New Orleans had to vote on the question of a bond issue for sewerage, water and drainage construction, Jupiter Pluvius, who appears here to be chronically unpropitiated, arranged matters so that

rafts, boats, hipboots and hacks were the order of the day. The vicious temper of the potentate above named toward New Orleans has been continually exhibited in acts both of commission and omission. The city gets at his hands an average of sixty inches of rainfall per annum; more than any other large city in the United States, and a great proportion of this unusual total rainfall he crowds into special seasons, days and hours with unprecedented rates; like a half-inch in three minutes, or one inch in ten minutes, or three inches in an hour, or eight inches in six hours; while at other seasons for weeks and even months he permits the dust to blow in our faces and accumulate on our roofs, and allows 60,000 elevated tanks of cypress wood (cisterns collecting roof water) on which the city depends almost exclusively for her water supply, to go dry and shrink until their open cracks show daylight through and through.

The partial construction of the drainage system which will be outlined to you with the next map (II) has greatly relieved the situation as to surface drainage, but with regard to sewerage and water supply New Orleans is as she has been for many years. As to sewerage, there is as yet no sewerage system. Fecal matter is deposited in shallow open pits with porous bottoms. Some of these are partially emptied occasionally by sanitary excavating companies who transport their contents in barrels to a point below the city limits and dump it into the river. Immediately after cleaning, these vaults are particularly offensive. In ordinary operation they appear to resemble the modern septic tank, and so long as they do not receive the greatly diluted flow which water closets yield they are not really bad and very rarely overflow. When, however, water closets are connected either to these vaults or to cesspools sunk deeper into an already saturated soil, then trouble begins and constant emptying at considerable cost discourages the owner, who finally constructs shallow drains near the surface, into the surrounding soil, or in a more direct, though unlawful, way allows overflow into an open gutter.

All kitchen, laundry, bath and other liquid household wastes go direct to surface gutters through flat and shallow alley gutters or pipe lines, and are what render the New Orleans gutter the reproach which it is, and which only a sewerage system can relieve.

In the matter of a water supply, the only other system than cisterns now serving in that capacity was constructed in 1836 and has been from time to time extended until it now covers some 125 miles of streets. The supply is taken from the Mississippi river, and without any purification whatever is delivered directly to the consumer. On an average the Mississippi river contains over two and one-half tons of mud for every million gallons of water. Unpurified, it is unfit for almost any use except lawn sprinkling, and between its comparative uselessness and its rather excessive cost it has gained but small patronage, having only about 5,000 premises connected with it. To be fair to the waterworks company, however, it should be said that the small number of consumers, and the large waste, by the city especially, has compelled the high rates, while the problem of an economical purification of a water of this character is one which has not been at all certain of solution until within a very few years past. The waterworks company made an effort at filtration in 1892 which proved an expensive failure, and thereafter (possibly quite naturally) claimed that the burden of proof as to an economical and successful method remained with those who still urged such purification on them.

In 1892 a franchise was granted to a private company for the construction and operation of a sewerage system, and a year of two afterward arrangements looking toward the drawing of plans and raising of money for drainage construction were inaugurated by the city. Mr. L. W. Brown was then city engineer, and was largely instrumental in getting work on drainage plans started. A strong advisory board of engineers was appointed, consisting of Mr. Rudolph Hering of New York and Messrs. B. M. Harrod and H. B. Richardson of New Orleans. Along lines suggested by this advisory board, and under Mr. Brown's supervision, surveys and investigations were made and eventually a general plan for drainage was recommended and adopted. Map II shows this drainage plan. Its construction has been about half completed at a cost of about $4,500,000.

The central power station is shown by a black hollow rectangle on the map. It contains eleven boilers and seven engines and each engine is connected with an electric generator. The combined capacity of these generators is 5,700 horsepower at the central station switch board, where the electric current destined for the operation of the several pumping stations is controlled.

From this switch board at the central power station lines carry wires to six different pumping stations called respectively No. 1, No. 2, No. 5, No. 6 and No. 7, shown on map by hollow black circles with designating number enclosed. At each of these pumping stations large motors are directly connected with immense centrifugal or screw pumps (depending on the lift required) and are operated as occasion requires by the electricity generated at the central power station.

As now operated, except for the common source of power, there are four separate and distinct drainage systems serving as many districts of the city and finding outlets at points marked on map respectively A, B, C and D, the first three outlets being into Lake Pontchartrain and the last into Bayou Bienvenue, which leads to Lake Borgne, some ten miles east of New Orleans.

The general scheme of operation is the same in each

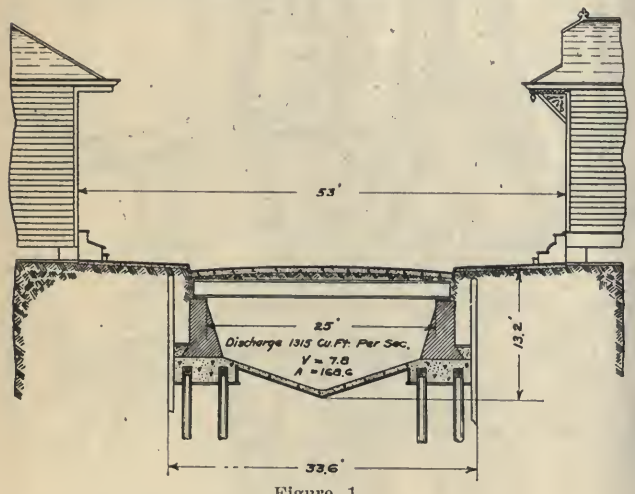


Figure 1.

of these systems, and a brief description of the system having its outlet at "B" will give the method of operation of the other systems as well.

Starting from the higher area along the river front, storm water flows down the gutters or drains of each street until it reaches the first line of collecting canals which run at right angles to and across the lines of natural drainage and intercept all of the flow which comes to them; further along similar intercepting canals collect the drainage from other areas. These intercepting canals are very shallow and small at their beginnings, but increase in size as their length increases; the necessity for slope to produce flow requires them to increase in depth also, since, in the direction in which they run, the ground is level; being short, however, they are not usually more than about ten feet deep at their junction with the main canals, which latter canals, due to the flow thus accumulated, can carry much larger quantities of water in proportion to their area and at lower rates of fall.

The result of this is that where a great many small gutters running directly to an intercepting canal a mile back from the river front would be overcharged and flood all of the streets through which they passed, the single large channel, properly lined and having the same slope, though far less area of cross section than the combined gutter areas, easily delivers the flow which reaches it to a pumping station much farther back from the river bank.

The St. Louis street covered and lined canal, which terminates at pumping station No. 2 and serves an area of about 1,200 acres, has a capacity to deliver to that pumping station 1,200 cubic feet of water per second. It has a flat top, is twenty-five feet wide, six feet high at side and eight feet at center, with "V"-shaped bottom.

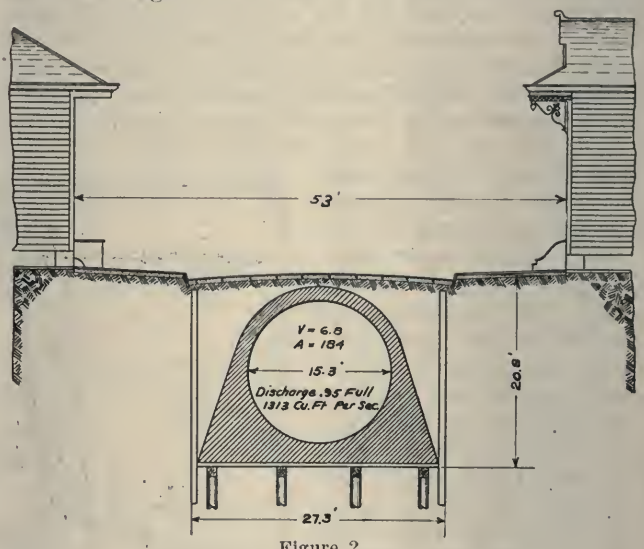

Figure 2.

A cross section herewith presented (Fig. 1) shows the construction of this particular canal, and alongside of it a circular sewer fifteen and three-tenths feet in diameter of equal discharging capacity (Fig. 2). You will notice that the canal section as adopted for New Orleans does not require nearly so deep an excavation as the circular section, depth being an important element, both of first cost and cost of operation where deep trenching

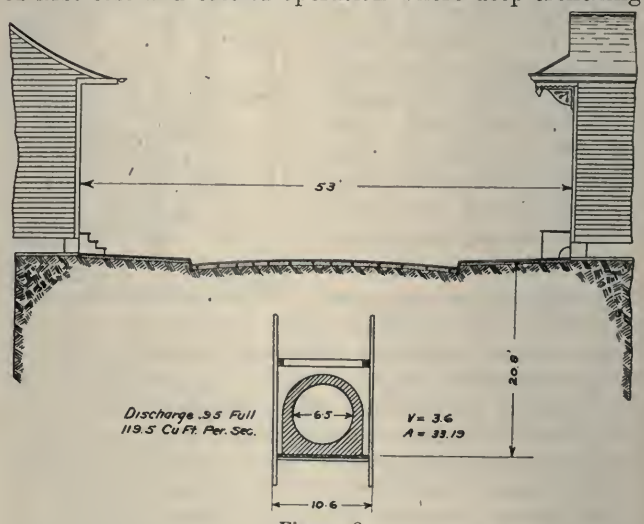

Figure 3.

is expensive and every foot of fall gained by such depth adds a foot of lift later to be made by pumping.

A third, much smaller circular section (Fig. 3) represents a circular sewer, six and one-half feet in diameter, whose carrying capacity, with the same slope, is found adequate to serve the needs of an area of similar size, density of population and surface conditions, in Chicago, as that served by the St. Louis street canal in New Orleans.

The great difference in size, and very much greater difference in carrying capacity in the St. Louis street canal, 10 to 1 as compared with the smaller circular section, represents an immense difference in cost, and is necessitated by the vastly greater rate of rainfall to which New Orleans is subject.

At station No. 2 an artificial outlet for the St. Louis street canal is created by pumping the water which it delivers to that station into the canal on the lake side of it. For the present, two screw pumps having a capacity to lift 250 cubic feet of water per second through a vertical distance of five feet are installed at this station. Future installations, according to the original plan, will raise the pumping capacity to serve this area to over 1,200 cubic feet per second, the 500 cubic feet capacity now existing has already been overcharged, though only part of the area is as yet paved, with a great percentage of impervious surface and adequately served with such local drains as must ultimately exist in order to give prompt and satisfactory delivery of the surface waters from each separate locality into the drainage canals. Improvement in these conditions can only come slowly with the development of the city, with perfected street pavement, etc., all of which tend to bring larger maximum rates of flow into the various parts of the main drainage system.

Having been lifted five feet at station No. 2, the water is carried by an open and unlined canal through a sparsely built area to station No. 7. In order to carry the required quantity of water and still maintain the surface of water in this open canal at a level that will admit of the inflow of the drainage from the area through which the canal passes, pumps at station No. 7 must remove the water which comes to them as fast as it comes and discharge it into the outfall canal on the lake side of the said station; beyond this point no further aid from pumping is available, and the pumps at station No. 7 must be able to completely empty the canals which drain to them into the lake level outfall canal which leads from them, i. e., to make a lift at times of as much as sixteen feet, although the greater part of the volume of water which they raise is not lifted nearly so far.

The present discharge of all storm water into Lake Pontchartrain is a temporary measure; the final plan of drainage, when completed, will divert all of the constant flow, and flow from even moderate storms, into Bayou Bienvenue and thence to Lake Borgne, ten miles east of New Orleans, where the deposit of street washings carried by the drainage system can do no harm.

This very desirable result will be accomplished by a series of canals joining pumping stations 1, 2, 3 and 5; said stations then, under ordinary conditions, will operate as follows:

All waters reaching station No. 1 will be raised into a canal leading to No. 2; all waters reaching No. 2 will be raised again into a canal leading to No. 3, etc., until station No. 5 is reached, when a much higher lift will be made into a level outfall canal, at gulf level, leading to Lake Borgne via Bayou Bienvenue.

Such a series of canals and pumping stations, in order to dispose of the future maximum run off from occasional excessive storms, would have to be of large proportions, and a careful study of the situation finally resulted in a recommendation that provision for about three-eighths of the maximum future run off be made toward Lake Borgne while the remaining five-eighths would be sent through relief canals into Lake Pontchartrain. Only two or three storms a year, possibly, would then find a partial outlet into Lake Pontchartrain, and the relative total amount of water and street washing so discharged would be of no practical effect, while the saving in cost both of construction and operation by such a disposal of occasional surplus waters was a very large amount. For the present the city is unable to undertake the Lake Borgne outlet, and all drainage is through the relief canals into Lake Pontchartrain, as above outlined.

The drainage pumps may be divided into two classes: Those which pump into outfall canals, thus making final disposal of the water which they pump, and those which make intermediate lifts delivering their discharge toward the final disposal stations.

The adopted plan of drainage, as outlined in the 1895 report, calls for an ultimate equipment of final disposal pumps that will have a discharging capacity of over 8,000 cubic feet per second; the present installation of pumps of this class amounts to 2,600 cubic feet per second, nominal capacity (the actual capacity is somewhat greater because the pumps are not called on to throw their maximum capacity and make their maximum lift at the same time, and can throw somewhat more than their rated capacity when working under lower heads).

In the matter of intermediate lift pumps, about 10,000 cubic feet per second capacity is the maximum ultimate requirement, and the present installation has only a capacity of about 1,100 cubic feet.

An adequate idea of present and future total pumping capacity as above outlined may be obtained if you will conceive that the water from all the pumps is frozen in the form of one continuous prism ten feet square as it leaves them; the present discharge would give you nearly half a mile of such prism every minute, while the ultimate rate of discharge would construct your prism at a rate of over two miles per minute.

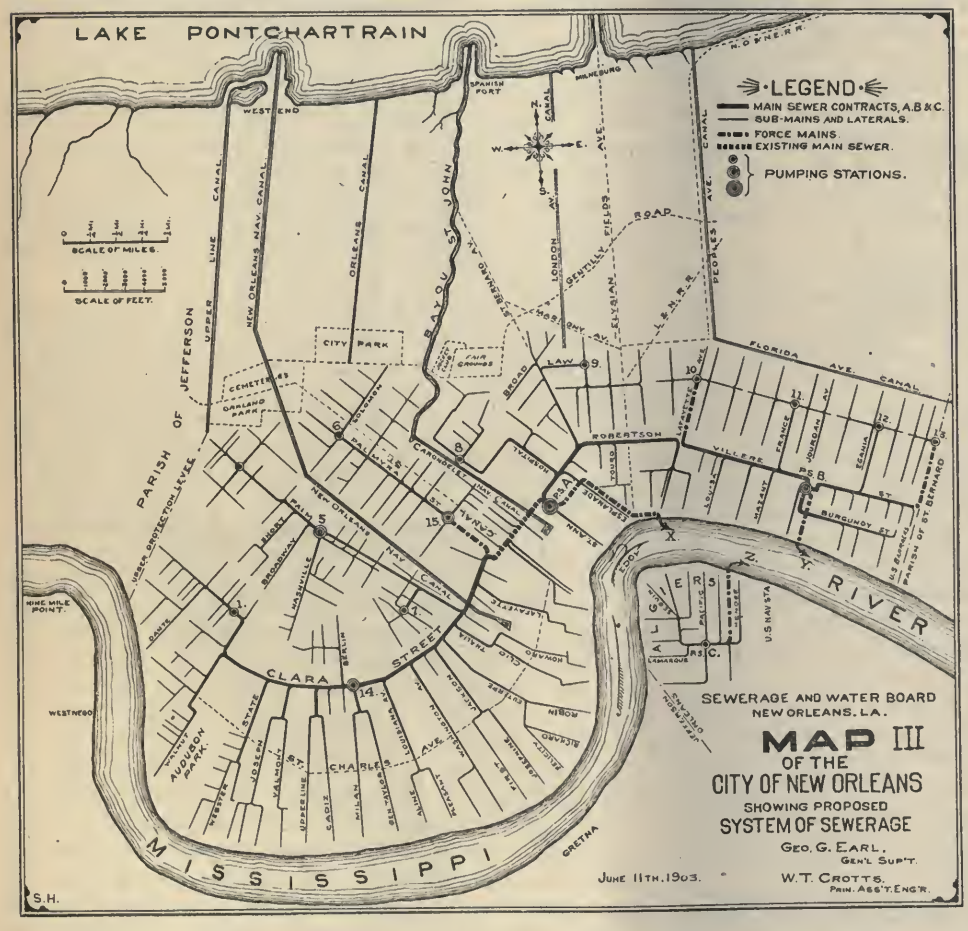
The proposed drainage system will have about sixty miles of canals. Into these canals storm water from about 700 miles of streets south of Metairie ridge must be delivered. Proper readjustments of gutter grades and laying of subdrain pipe and street paving will eventually perfect this essential feature of improvement, but this development will be tedious and expensive, and can not cover fully every inhabited portion of the city for years to come; even if it could the drainage system of New Orleans could not properly receive the dry weather flow of house sewage for the following reasons:

First, the subdrainage arteries would be too shallow to afford a proper fall for house connections to enter them, and must themselves be so large and flat that the small stream of fouled liquid wastes could not be successfully carried in them, but would form deposits and putrefy.

Second, the outfall canals of the drainage system would, in dry weather, be converted into elongated open cesspools of the most objectionable type.

For these reasons the sewerage of New Orleans is a separate problem and because it must deal with the fouled water originating from the water supply, and passing away as domestic wastes the two problems have certain vital points in common. There is no possible source available for a gravity water supply, and no possible point for a natural gravity sewage outlet; therefore, pumping must be resorted to for each, and all costs, both of construction and operation, hinge on the question of "how much water per capita shall be assumed in designing the systems."

The average water consumption has been assumed at 100 gallons per capita per day, and the water distribu-



tion system has been designed on this basis, making due allowance for the usual fluctuations of demand incident to the needs of the community, including a fair allowance for fire extinguishment. The next common question is area of territory to be served and density of population on that area. We have drawn both water and sewerage plans to serve the twenty-three square miles of area south of Metairie ridge when said area shall contain 850,000 people. At present thirteen square miles of this area contain about 300,000 people, and the remainder is mostly open. Present construction in both sewerage and water-works systems will only cover the well-populated area.

Turning now to Map III, I will very briefly describe the sewerage system as now proposed. I should say, first, that the private company which undertook a sewerage franchise in 1892, after spending nearly $300,000 on plans and construction, went into the hands of a receiver, and its works and rights were finally purchased by the city in 1902.

A sewerage plan naturally centers about and depends on the available point for outfall, or disposal of sewage. For New Orleans, beyond any possible doubt, the Mississippi river is the proper point for disposal. By a discharge of sewage, below its surface, into its direct current, almost infinite dilution is accomplished and, provided your point of discharge is not into, or above the eddy, you have also instant and continuous removal.

The map shown indicates the lowest considerable eddy existing in the river at New Orleans, and any convenient point below this eddy, on either bank of the river, will receive and effectually remove the sewage of the city. Points on this map marked "X," "Y" and "Z" are the points at which the sewage will be discharged into the river, and points marked "A," "B" and "C" show locations of the pumping stations at which the centrifugal pumps will drive the sewage into castiron force mains leading uphill to the river. The maximum lift which any of these pumps will make will be fifty-five feet.

At station A, where most of the sewage will be collected, the pumps will be operated by steam power and there will be located there also electric generators that will furnish the power to run all of the other pumping stations required for intermediate sewage lifts in the system on the east bank of the river and indicated by circles on the map, numbered from 1 to 15, inclusive. These intermediate lift stations will be connected with station "A" by wire lines laid under ground as the sewers are laid, and will be very small affairs; merely wells into the bottom of which a low level sewer will enter, and in which motor-driven centrifugal pumps, arranged to stop and start automatically with the rise and fall of the sewage in the well which they occupy, will lift the sewage some eight or ten feet and discharge it into another sewer at a higher elevation.

The proper location of these pumping stations, and the most advantageous and economical arrangement of the collection system leading to them, is the whole secret of sewer design for New Orleans. Years of study have developed the system as outlined on the map shown; every available foot of natural fall is used to the utmost, and the principle of concentration of flow as outlined in connection with the drainage plan is applied with immense advantage.

The map before you only gives the main lines into which the flow from the local areas is concentrated.

As designed, 87 per cent. of the total mileage of sewers will be eight-inch laterals laid with a fall of one foot in 300 feet, with their tops nowhere less than five feet below the surface and seldom more than nine feet below the surface. At each dead end (i.e., the head of each lateral sewer) an automatic flush tank will be placed, which will be gradually filled with clear water from the water-works system, and once every twenty-four hours will discharge all at once some 250 gallons of water, thus creating a cleansing current at the extreme upper end of each lateral sewer. Beside the sewage proper and the flow from flush tanks the sewers will also receive a considerable amount of ground, or seepage water which, no matter how carefully the joints are made, will find its way into them. In calculating the size of the sewers we have estimated that about one-third of the annual rainfall will gradually sink into the soil and run off through the sewers as a constant ground water flow. The under-drainage of the soil thus ob-

tained will be of advantage from every point of view, decreasing the saturation of the soil and guaranteeing, even during the early life of the sewers, a sufficient volume of flow to procure good velocities.

The system as designed, when working at its full capacity, or even when the sewers are half full, will carry sewage at gradually increasing velocities, ranging from two to three and one-half feet per second, from the most distant portions of the system to the final disposal pumping stations. Every pumping station will create, continually, an artificial low outlet for all of the sewers draining to it, and the flow in the sewers themselves will be only due to their fall, and as certain as the laws of gravity which hold, even for New Orleans. The very longest line of travel from point of origin to river outlet will be 7.8 miles, and this distance will be covered in less than five hours, before putrefactive changes have had time to manifest themselves, in channels which are smooth, clean, well ventilated and designed exactly to perform most efficiently the one particular object of sewage removal.

The question of a water supply begins naturally at its source. For New Orleans there is simply no possible gravity source of supply. Local artesian waters are bad in quality, inadequate in quantity and beyond consideration in the cost of either constructing or operating a system of water supply for a large city.

North of Lake Pontchartrain there are several water sheds, already referred to, which would furnish, or could be developed to furnish, a very desirable water supply of soft and reasonably clear water. Local population on their area and a certain amount of color, of vegetable origin, and of fine silt in suspension would necessitate filtration for any one of these waters, but they would not be difficult to filter. The nearest and cheapest of these projects, however, would require a pipe line forty miles long, mostly through a gulf level marsh. The delivery of forty million gallons per day through a forty-eight inch pipe line for such a project would necessitate the construction and operation of two pumping stations, each capable of lifting water 220 feet to overcome the frictional loss in the level pipe line and deliver the water into a tide level reservoir at New Orleans, after which filtration and pumping for distribution would still be necessary.

The cost of such a forty-mile pipe line and pumping stations to force water to the city would be over $4,000,000, or very nearly all that the city has to spend in waterworks construction, so that nothing would be left to construct filters, pumping station for distribution, or a system of distribution pipe over all of the streets of the city; which last-named works stand ready to consume the whole fund available for water-works construction, and without which an abundant water supply in Africa would be just as valuable an asset to New Orleans as though it were at the city line. Evidently the supply from over the lake is beyond present consideration. There remains, then, only the Mississippi river. Its advantages as a source of supply are manifest. It is at our door and inexhaustible; in many respects it is a most desirable water, being low in bacteria, free from odor and color, and cool and pleasant to the taste and showing practically no evidence of sewage pollution. It is, however, not a soft water, since it contains a fair amount of the carbonates and sulphates of lime and magnesia in solution, and it most certainly is not a clear water, being, on the contrary, at New Orleans, almost always very muddy, and a large proportion of this suspended matter is composed of submicroscopic clay particles which it refuses persistently to part with in any reasonable period of subsidence. It was evident to the author of this paper, when he was elected to his present position in 1900, that the problem of the clarification of Mississippi river water must be solved successfully and economically if the present generation was to see an adequate clear water supply in New Orleans. A careful study of investigations lately made at Louisville and Cincinnati looking to the purification of somewhat similar waters convinced him that a study along the same lines at New Orleans could not fail to point a proper solution, and he, therefore, immediately commenced to urge the necessity for such an investigation.

The advisory board of engineers which was consti-

tuted a little later also urged an early investigation in this connection, and the sewerage and water board promptly appropriated the necessary amount of money for its execution. The investigation was carried out under the personal supervision of Mr. Robert Spurr Weston, resident expert, along lines approved by Mr. Geo. W. Fuller of the advisory board of engineers, who had conducted the similar investigations at Louisville and Cincinnati, and resulted in demonstrating an economic and efficient method of purification for Mississippi river water at New Orleans. I understand that Mr. Fuller will present you a paper on water purification, and will leave in his hands any general discussion of this subject, only giving in very hastly outline here a description of the plant which is now being designed to carry out the method of purification which was shown to be most efficient and economical to meet the local requirements.

Map IV shows the proposed pipe distribution system for the delivery of water throughout the city, and at the left-hand side of the plate, along the upper city line, is the proposed location of the pumping and purification plant. Seventy acres of ground will be needed when New Orleans has 1,000,000 of population, and that area will be acquired now. The advantages of the particular location chosen lie in the facts that it takes its water from the river above the city, is near enough to the river to allow of the location of all pumping machinery under one roof, is in proper line and will serve equally well as a purification and distribution station if later it should become advisable to go higher up the river for a supply, or even to bring in water from across Lake Pontchartrain, and that from it better than any other point in the city an economical distribution system, adequate to present needs and extensible to conform with future requirements, can be constructed. The distribution system, both present and future, will have to speak for itself from the map while we trace briefly the outline of the proposed purification and pumping plant.

An intake will be located at the low water shore line of the river, at the upper end of the city. The suction pipe will terminate in this intake, and river water, always taken from near the surface where the turbidity is least, will be admitted into this intake. The suction line from the intake will be a level line nearly a mile long, and laid two feet below the lowest water level in the river. Through this line centrifugal pumps will draw a constant stream of water, containing an average of 650 parts per million of suspended matter and will discharge it at the bottom and the back end of a masonry reservoir ten feet deep and holding about twelve hours' supply for the city; at the other end of this reservoir, from its top, a skimming weir will collect an equal amount of water which will be found to have lost an average of 35 per cent. of its suspended matter by twelve hours of plain subsidence. To this water then a coagulant will be added and, after thorough mixing, the whole will pass into the bottom at the back end of the coagulating reservoirs, where again twelve hours of subsidence will be allowed, after which the effluent of these basins will be skimmed into a collecting conduit leading to the filters. The rate of application of coagulant will be so proportioned that when the water reaches the filters not more than 50 to 75 parts out of the original average of 650 parts per million of suspended matter contained in the river water will be carried over and this last contingent of persistent turbidity will have been so altered in its form that, whereas in its original condition a very slow passage through a thick layer of fine sand would not have removed it, in its present condition even rapid passage through a thin layer of relatively coarse sand will suffice, not only to remove the last trace of it, but to enmesh as well a very high percentage of the bacteria which the water contained. As coagulant, sulphate of alumina will probably be used, an average of about four grains per gallon of water being required.

The filters are merely thin layers of sand underdrained each to a single discharge pipe terminating in an automatic controller by means of which the rate of passage of water through the sand layer is regulated. When the sand layer becomes clogged by the retained suspended matter the filter is cut out of service and cleaned, first by forcing air and then filtered water at a very high rate backward through the sand layer, thus loosening and removing the deposit which is collected by overflow into channels just above the sand layer and drained off into a sewer. Three or 4 per cent. of the water filtered will be required for washing the filters. Beneath the filters will be a small clear water basin from which the water will flow to the pumps which will either force it directly into the mains of the city distribution system, under a pressure of about ninety pounds per square inch, or else raise it into covered clear water reservoirs where it will act as a reserve supply to tide over periods of greater demand when the flow from the filters is insufficient.

A year's operation of the system, just above roughly outlined, during our investigation never once failed to yield continuously a perfectly clear water which satisfied every practical hygienic test for purity, and there is no reason why an intelligent operation of a larger plant should in any degree fall short of equally good results. The process, however, requires a high grade of supervision, if its best results, both in cost and quality, are to be obtained.

The foregoing attempt to cover the three topics of the sewerage, water and drainage of New Orleans in brief descriptive form, within a compass that would really be too short to even treat adequately either project, has necessitated the utmost simplification of even the general subjects, and the passing over of all detail.

These works, to accomplish ends long held to be impossible by many citizens of New Orleans, have really been reduced to such simple and certain general form that their successful operation is now beyond question. All three of the plans are the "boiled down" results of many more pretentious efforts. The simplicity of general features is their greatest strength.

Many details are less simple, but it is probable that further study and the application of experience gained elsewhere up to the time of complete construction will result in a further simplification even of such details. Especially is this true in the water purification plant, which plant, as applied to waters of the character of the Mississippi river water, represents an art whose birth and development is of the last decade, and one in which for some years to come, at least, every effort must bring added evidence for the more positive determination of the large number of variable factors which must be most advantageously combined to produce the best results at the least cost.

We are certain that we can purify Mississippi river water at an additional total cost for purification of not over one and one-half cents per 1,000 gallons. This seems a very modest sum and if quoted at the cost per pint it would sound even better, but a great city uses millions of gallons, and in our case for 40,000,000 gallons of water it amounts to $600 per day for the removal

of about 100 tons of mud and 98 per cent. of the bacteria. It is well worth the cost, and more if necessary, but very small items of improvement as they can be developed aggregate immense savings and are, therefore, decidedly worth while.

The total expenditure available for sewerage, water and drainage construction by the end of 1908, when the aim is to have practically completed the sewerage and water system, will have been about $18,500,000.

602 Carondelet Street.

DISCUSSION.

Dr. G. T. Swarts, Providence, R. I.—Is there any underground system at all in New Orleans, or is it all open canals?

Mr. Earl—The drainage system is covered and lined pretty well throughout the populated area of the city. However, that only covers about sixty out of four hundred miles of streets, so that, in effect, all of our sewage at present goes to surface gutters, and eventually gets into the drainage canals which intercept the flow from the surface gutters; there being no sewerage system proper, in any sense of the word.

Dr. Swarts—No pipes, drains or brick sewers under the ground?

Mr. Earl—No, sir; except in individual cases, such as the Charity Hospital and a number of places which have force mains running to the river through which they discharge by pumping.

Dr. Swarts—What about the St. Charles Hotel, for instance?

Mr. Earl—It has a force main and pumps its sewage into the river. So also do a number of the leading hotels, the Charity Hospital and other public buildings.

Dr. Swarts—They build, I suppose, below the proposed intake you mentioned?

Mr. Earl—The proposed water-works intake is at the extreme upper end of the city, and everything that goes into the river is below that intake. You know, we have some fifteen miles of river front.

Dr. Swarts—From an engineering standpoint I would like to ask why the pumping stations are placed so far from the river; why should not the pumping be done at the river?

Mr. Earl—It was a question, first, of the acquisition of the necessary area; we have to get land where it can be reasonably acquired, where it is not much built up. Beside, it fits in better in the matter of distribution. From the point chosen you get the shortest line of transmission to your center of population for your large water mains.[1]

Dr. J. S. Fulton, Baltimore—I remember, six or seven months ago, seeing a sample of the water here. It had been standing for some length of time, but had not yet deposited its milky sediment. Will the proposed plan of filtration exclude that in any way? Will chemical precipitation get rid of that sediment or is there any mechanical way of doing it?

Mr. Earl—The fine particles you speak of can only be gotten out by coagulation. Filtration without coagulation fails almost every time to entirely clarify the water, and no term of subsidence will bring out that milky deposit. It is submicroscopic matter that will not go down except by means of a coagulant. After being properly coagulated it is easily removed by filtration.

Dr. Swarts—How long will the filter operate?

Mr. Earl—From 12 to 24 hours between washings.

Dr. Seneca Egbert, Philadelphia—In my humble judgment the city of New Orleans is going at the problem in the right way, and they seem to forestall, as far as they can, the various questions that may arise as the city grows larger. I was especially glad to see that they intend to use the separate system in a large part of their sewerage plan; and the idea of the pumps at the substations driven automatically by electric motor, using power from a central station, was very unique to me. It struck me as a clever solution of a difficult problem. It may have been tried in a crude way before, but I do not know of any place where it is done on such a large scale as here. I think, with the longest lines not over eight miles in extent, they will get a speedy removal, within five or six hours, of their sewage, which means the elimination of a great deal of annoyance, offense and danger from stagnant or decomposing sewage.

Of course, as to the water supply, we have to take their word about the sedimentation, coagulation, etc. It is interesting to learn that coagulation will be used on such a large scale, and also that the work can not be done with the sand filters that are working so well elsewhere, as, for example, in Albany, N. Y. But I understand the problem that confronts this city, and can appreciate this solution of the problem.

1. This question and reply referred to the water works pumping stations. The sewer pumping stations are located on the lines of most economical gravity collection in low areas; from such stations shallow force mains leading to the river are much cheaper than the very deep sewers that would be required if pumping stations were located on the river bank.

THE PURIFICATION OF WATER SUPPLIES BY SLOW SAND FILTRATION.

(*Concluded from page 967.*)

IV.

WATER FILTRATION IN THE UNITED STATES (CONCLUDED).

C. THE PHILADELPHIA FILTER.

The city of Philadelphia has long and faithfully served sanitarians as a text for discourses on the effect of polluted drinking water. Not only has the physical character of the city water, as drawn from the tap, ordinarily been sufficient to excite the repugnance of every stranger who has tarried for a while within the gates, but the citizens of Philadelphia themselves have for years suffered so severely from typhoid fever that the local conditions have been a by-word and a reproach all over the United States. Civic pride, some of which undoubtedly exists in Philadelphia, can hardly contemplate with equanimity the yearly tale of youths and maidens offered up to the Minotaur of ignorance and neglect.

At intervals, during more than a quarter of a century, various public-spirited organizations have employed experts and commissions to report some plan for purifying the water supply and for abolishing the source of so much municipal suffering and disgrace. All these projects, however, although they have been worked out with more or less elaboration and usually with due regard to the state of knowledge concerning water purification at the time of their presentation, have not until very recently received serious consideration by the responsible authorities. About 1898-9 an outbreak of typhoid fever of unusual severity caused even the supine municipal authorities of Philadelphia to recognize the imperative necessity for immediate action.

In 1899 a commission of distinguished engineers appointed by the mayor presented a report recommending (1) the adoption of a project by which the waters of the Schuykill and Delaware rivers should be purified by filtration; (2) the immediate improvement of the existing plant in accordance with the detailed recommendations of their report. This report, in its main features, has formed the basis for the final plan for filtering the entire city water supply, and at this date the construction of a comprehensive filtration plant is well under way.

One feature in the situation at Philadelphia demands consideration not so much from its rarity as from its deplorable frequency of occurrence in American cities.

This is the enormous consumption of water as compared with the consumption in all European cities and in some of the more carefully controlled American municipalities. All responsible authorities are agreed that the Philadelphia consumption of 175 to 200 gallons daily per capita indicates excessive waste. When so large an amount of water is demanded by a municipality, the cost of constructing proper filtration works is proportionately enhanced and in some cases may prove an insuperable obstacle to the installation of a suitable plant. It is well known that the consumption of water can be reduced to a reasonable point by the introduction of the metering system and other devices, which tend to diminish avoidable and wilful waste. "Consider, if you please, what would happen to the city gas-works if bills were collected according to the size of the house and the number of fixtures, the charge being the same whether gas was used in an economical and modern manner or whether every jet was lighted and allowed to burn all night and all day long, too, for that matter. You will see that with such a system gas would be deliberately wasted on every hand and the consumption would increase to several or many times the normal and proper amount. As the works would not be operated at a loss the rates would be raised to cover the needless use of gas and would be much higher than would be necessary under economical conditions. This condition of affairs is so absurd that it is difficult to give it serious consideration, but it is precisely what is being done in the water department, in spite of the urgent protests and appeals of the present chief and of his predecessors for the substitution of a more rational and business-like basis."

The plans for the yield of water from the Philadelphia filters are on a most liberal scale, and if reasonable measures for the restriction of water waste are gradually introduced the cost of filtration to the citizens of Philadelphia should not on this ground prove excessive. The city of Philadelphia has in the past derived its water from the Delaware and Schuylkill rivers, over 90 per cent. of the supply coming from the latter source. The Schuylkill river has been the recipient of sewage not only from a rather densely populated watershed, but from important suburbs of Philadelphia itself. A large amount of the drainage from these suburbs has been permitted to enter the river only a short distance above the city waterworks, and, although attempts have been made to lessen this pollution by the construction of intercepting sewers and in other ways, recent investigations and occurrences have shown that the Schuylkill is still grossly and dangerously contaminated. In addition to receiving a mischievously large amount of sewage, the Schuylkill is most objectionable from the point of view of its mineral constituents. Near its source it receives sulphuric acid from the oxidation of the sulphid of iron in the coal, and this sulphuric acid is neutralized during the passage of the river through extensive limestone formations, so that the reaction of the river water, on reaching the city, is excessively "hard" and unsatisfactory. The river also passes through a soft red shale which is easily disintegrated and at certain times contributes its quota of suspended matter to the stream. Mr. Trautwine, who was for some years chief of the bureau of water, writes as follows concerning the mineral matter in suspension:

> In times of flood this formation (the red shale) sends vast volumes of its substance in suspension into the stream, which at such times runs blood red. The first effect of a general storm is therefore a visitation of red mud, which a day or two later is followed by water charged with coal dust. The writer has seen water drawn from faucets in Philadelphia, after storage in the city reservoirs, so black from coal dust as to be scarcely distinguishable from ink.

The serious character of the task thus confronting the citizens of Philadelphia and the necessity for radical action can be readily appreciated from the facts just given. The custom of supplying an inordinate quantity of water, combined with the unfortunate character of the Schuylkill, both as regards mineral and organic constituents, caused the path toward water purification to bristle with unusual difficulties.

A very fortunate solution of the problem, albeit an expensive one, has been found. This is nothing less than the virtual abandonment of the Schuylkill as the source of the main city supply, recourse being had to the Delaware river for the major portion of the new supply. This involves practical reconstruction of a large portion of the distribution system and entails the reorganization of the whole system of expensive reservoirs and pumping stations. Taken in addition to the cost of filter construction proper, it will be seen that the expense of the whole sweeping improvement will be indeed formidable.

Filter beds are now being constructed in four separate localities: (1) At Belmont on the west bank of the Schuylkill, comprising eighteen filter beds and designed to supply West Philadelphia, a region of the city which in the past has been a severe sufferer from typhoid fever. Ultimately 26 filters will be installed at this point. The water for this plant is taken from the Schuylkill. Ample space is allotted for a sedimentation basin and a pure water reservoir, and space is available for the extension of the system when necessary. (2) Lower Roxborough, on the east bank of the Schuylkill, is equipped with five filter beds which have been in operation some months. (3) Upper Roxborough, a plant of eight filters, some of which are now in operation. The upper and lower Roxborough stations are designed to supply the Germantown district. (4) The main filtering plant in the new system is at Torresdale on the Delaware river, well above the influence of the city sewage and in a district adapted for filter-construction. Here an enormous plant of fifty-five filters is being installed, with prospects that ten more filter beds will be contracted for in the near future. The total capacity of the Torresdale works, after preliminary rapid filtration of the water, will be 248,000,000 gallons daily.

The method of construction is substantially the same at all of these stations. The first filter beds built, those at lower Roxborough, are about half an acre in area and are somewhat smaller than the later filters, those at Belmont and Torresdale being about three-fourths of an acre each. Full advantage has been taken of the experience gained in the construction and operation of the Albany filter and several improvements suggested by recent American experience have been carried out. The filters are all covered, and both piers and vaulting are of concrete, a construction device that marks an advance over the brick piers laid at Albany. Great care is being taken at Philadelphia in the arrangement of the graded layers of gravel, five layers, ranging from six inches to one inch in thickness, being used. An ingenious and most economical contrivance is being employed at Roxborough for removing the scraped sand from the surface of the bed to the central court, where it is washed and stored. In the older works the "scrapings" are wheeled out in barrows. The new sand-ejector invented at Philadelphia, by means of which the sand, shoveled into a hopper

directly from the surface of the bed, is conveyed by a stream of water to the outer court, ought to diminish very greatly the expense of operation.

During the course of the work many experiments have been made under the direction of Mr. Hill, chief engineer in the work of construction, and some of these led the officials to believe that by subjecting the water to preliminary rapid filtration through layers of gravel, slag and sponge it will be possible to operate the slow sand filters at a rate far beyond that which is customary when raw surface waters are applied directly to the sand beds. It is even believed that as high a rate as 6,000,000 gallons daily per acre can be reached after this preliminary treatment. If the event justifies this hope, the filtering surface needed to supply the city, even with its present exorbitant demand, can be greatly reduced. It is estimated that the Torresdale filter-beds alone will supply more water than is obtained by the city of London from all sources, over twice the daily consumption of water in Paris and four times that in Berlin.

The general opinion prevails among informed engineers that the construction of the Philadelphia filter plant is being conducted in a careful and efficient fashion, and that when the works are completed they will compare favorably in point of good construction with any similar undertaking. It is most unfortunate that, together with this belief in the high character of the work as actually performed, there should be a very general feeling that the price paid for the work by the city is inordinate. Rumors of favored contractors, of large "rake-offs" and of a general atmosphere of "graft" are so common in connection with the discussion of the Philadelphia situation that one is reluctantly compelled to lend them credence. It is, for example, a well-known fact, and one that is openly discussed, that all employes engaged in the work are assessed for "campaign funds" on a graded scale. It is said that 1 per cent. is levied on salaries up to $1,200, 1.5 per cent. on those up to $2,000, 2 per cent. on those from $2,000 to $2,500, and that even those holding high positions are not exempt. It is alleged on excellent authority that promotions are controlled absolutely by political influence, and it is claimed that some of the ablest engineers engaged in the work at the outset have been gradually driven out by a swarm of political appointees. It is surely unfortunate that so great an undertaking, involving the coöperation of many scientifically trained engineers and investigators, should thus suffer from being dragged in the slime of politics. The situation is one of general interest and concern. It is not a matter of merely local importance that the Philadelphia filter plant should be costing so much more than it ought to legitimately, but the event affects all cities interested in water purification, since a large expenditure at Philadelphia will be used as an argument for opposing the introduction of purification methods into other municipalities, on the ground of the costliness of the undertaking.

Museum Appliance.

ROUND OR SQUARE JARS FOR MUSEUM SPECIMENS.

D. S. LAMB, M.D.,
Army Medical Museum.
WASHINGTON, D. C.

An objection and, so far as I know, the only objection to the use of round jars for museum purposes is that the round jar distorts the view of the specimen. After many years experience in museum work I believe that the objection is more theoretical than real; practically there is no difficulty in getting a satisfactory view of specimens in round jars. The same objection, of course, would hold against the "Buchhold" preparations and against all specimens mounted under bell glasses. I believe, however, that in these cases also one who examines the preparation is brought so near it during the examination that the distortion is practically unrecognized.

On the other hand, the round jar has many advantages which I believe far outweigh its one disadvantage. The following may be mentioned:

First, the simplicity of the round jar, consisting as it does of but two parts, the jar proper and lid, both made of glass. The lid is ground so that it closely fits the mouth of the jar and thus prevents the entry of dust and evaporation of the preservative fluid. The matter of evaporation is of importance for some fluids, especially alcohol, but of little moment where hygroscopic fluids like glycerin are used. The square jar is fitted with a glass or metal top or cover which is either cemented tightly to the jar or not; if it is, it of course prevents entirely the removal of the contents of the jar. Otherwise the top is clamped to the jar by means of two metal or wooden screws. Some jars have also a bottom plate which is fastened to the top plate on each side by two pillars and these are made tight by nuts. To prevent evaporation and keep out dust, a rubber pad or ring is inserted between the plate and jar; and if there is also a bottom plate another pad is inserted there to avoid the shock of the jar against the plate. It hardly needs to be mentioned that the square jar is complicated as compared to the round jar.

The second advantage of the round jar is the ease and rapidity with which it may be cleaned and emptied. The cleaning is as simple as is the construction; its contents can be quickly changed and its contained specimen can be removed and replaced in a moment.

To keep the metal work of the square jar clean and bright would be a task indeed in a museum of some thousands of jars. The brass mountings quickly tarnish and indeed at the best the jar with its mountings lacks the beauty and grace of the round jar. And to change the contents or remove the specimen from the square jar requires the unscrewing of the clamps and removal of the rubber pads. Sometimes the screws are rusty and the rubber often adheres to the glass so firmly that it has to be torn away and is ruined in doing so. It must be stated in fairness that sometimes the lid of the round jar sticks closely to the neck and requires to be tapped with a mallet to be loosened.

Third, an objection to the rubber pad and ring is that some preservative fluids act on the rubber, rotting it and causing not only a discoloration of the fluid itself but a permanent discoloration of the specimen.

Fourth, the round jar has attached to the under side of its lid a hook on which the specimen may be hung by a thread; the removal and replacing of the specimen is thus made easy. Nothing could be more simple. The absence of the hook from the square jar (for it is usually absent), renders it necessary many times to make a glass frame to which the specimen may be attached; this frame is of course very liable to be broken, in which case a new one is necessary.

Fifth, the round jar adapts itself to the shape of many specimens such as the entire brain and heart to which the square jar is hardly ever suitable; and almost any specimen can be mounted to look well in a round jar. The esthetic effect is of some importance, indeed of much importance to a museum.

Sixth, there is no difficulty in obtaining round jars of clear glass, whatever the size. Most of the square jars in the market are not clear and are not of even thickness, which is a serious objection also, since the wavy and uneven glass must cause some distortion of view.

Seventh, the cost of round jars is, I believe, about one-third that of square jars of the same capacity and of good quality.

It seems to me that a consideration of all the advantages named would give the preference to the round jar, especially in the case of a museum of any size.

EXAMINATIONS FOR MEDICAL STUDENTS.

The American student, more than the medical student of any other country perhaps, dreads what he calls the "ordeal" of an examination. Teachers and students both, especially in the middle and western states, are apt to inveigh against the evils of examination systems, sometimes, perhaps, without regarding sufficiently the advantages which are derivable from well-conducted examinations. In many medical schools students are subjected to no examinations at all, except a superficial test at the end of each individual course; in other schools there is one great final examination at which the student either succeeds or succumbs, this examination often being limited to the clinical branches alone on the theory that the clinical work necessarily includes a knowledge of the practically important portions of the fundamental sciences; in still other schools yearly examinations are imposed, the student being subjected each spring to an examination covering the whole of the subject matter studied since the preceding October; finally, some few schools and in Canada some of the provincial governing boards have instituted a primary and a final examination, the former covering the work in the fundamental branches of the first two years, the latter the work in the clinical branches of the last two years, a system not unlike the one prevalent in Germany and in Austria.

It is not our purpose at this time to enter into a discussion of the advantages and disadvantages of various examination systems, nor to say anything in detail about the conduct of an ideal primary or final examination, though we may perhaps do so later. We desire, however, to say a word about one feature of examinations for medical students that is too frequently overlooked, namely, the educational function subserved. Too often by both student and teacher it is the selective function of an examination alone which is considered—the examination is regarded as a sieve which lets men whose attainments are of small dimensions fall through. But this selective process ought to be the least important feature of an examination. The main stress should be laid on the educational value of the test. The clearness of thought, the accuracy and brevity of statement, the avoidance of tautology and irrelevant assertion that a properly conducted written examination cultivates, are qualities too often found wanting in the writings of those medical practitioners who have not gone through, as medical students, the careful training that a well-conducted series of examinations can give. Again, an oral examination demands presence of mind on the part of the student, a readiness of wit, a coolness and freedom from embarrassment, if he is to do his best—and these also are qualities which, if well developed in student days, will stand the physician in good stead at the bedside and in the consultation room in later years. In a good practical examination, conducted by a master of the subject examined on, the student has the opportunity of showing what he has learned to do, rather than what he has remembered by cramming, and of illustrating the extent of his assimilative knowledge rather than the dimensions of his portative capacity.

The educational value of an examination will, of course, vary enormously with the character and professional ability of the man who sets it. An examination ought always to be a sanction for the highest kind of teaching in the course or courses preceding it, and ought by its results to set the stamp of approval on the best kind of study and practical work. We shall not have solved the much vexed examination problem until we find that those students stand highest at examinations who, having the best natural capacity, have had the best instruction, and have done their work in the best possible way.

FAITH HEALING AND CRIMINAL NEGLECT IN NEW YORK.

A very important legal decision as regards the practice of faith healing was handed down last week by the Court of Appeals of the State of New York (in that state the court of last resort) in the case of the People vs. Pierson. The defendant, a follower of John Alexander Dowie, was sentenced two years ago to pay a fine of $500, or undergo 500 days' imprisonment for criminal neglect in failing to call a physician to attend an infant adopted daughter in a case of pneumonia, which eventually proved fatal. Under the penal code in New York, a person who omits without lawful excuse to perform a duty by law imposed on him, to furnish food, clothing, shelter or medical attendance to a minor, is guilty of criminal neglect and is liable to fine or imprisonment, or both, according to the will of the judge. Pierson's case was selected by Eddyites and faith healers generally as a test, and was taken to the court of next resort, the appellate division of the Supreme Court, which reversed the decision of the original trial court, holding that medical attendance as referred to in the criminal code does not signify absolutely the attendance of a regular medical practitioner in the ordinary sense of that term. Money was liberally donated from all over the country by those interested in faith healing, and eminent counsel was employed so as to secure, if possible, a favorable decision. The Court of Appeals now

reverses the decision of the appellate division and upholds the original conviction. In the opinion of the court, as written by Justice Haight:

> It would seem that the legislative intent is reasonably clear, although possibly more concise language could have been employed. The section of the code under which the indictment was found contemplates that there are persons on whom the law casts a duty of caring for minors. Sitting as a court of law for the purpose of construing and determining the meaning of statutes we have nothing to do with variances in religious belief and have no power to determine which is correct. We place no limitations on the power of the mind over the body, the power of faith to dispel disease, or the power of the Supreme Being to heal the sick. We merely declare the law as given us by the legislature. We find no error on the part of the trial court which calls for a reversal.

This is the first time, we believe, in this country that a court of last resort has decided this vexed question of the bounden duty of parents and guardians to furnish proper medical attendance to minors. It is all the more fortunate that this decision comes in perhaps the most important state of the Union and from a court whose opinions are held in high estimation all over the civilized world. This declaration of the meaning of a statute is expressed in no doubtful language and formulates with absolute clarity the sentiment that must be supreme in such matters unless confusion is to supervene. It should apparently not be a difficult matter to secure the enaction of corresponding statutes in states where they do not already exist. There is no doubt that this opinion of the Supreme Court of New York will stand as a precedent to be followed in all future decisions in this matter under corresponding circumstances. The decision is all the more welcome and must prove a source of encouragement to those who are striving faithfully for the extension of proper medical regulations since it followed the reversal of the trial court's decision by the appellate division—a reversal which proved a serious setback to those who were honestly laboring to save misguided individuals from the unfortunate results of their own illusions and especially to preserve the minors under the charge of such individuals from suffering at the hands of their legal guardians. There seems every reason to hope that even more good than can be anticipated at the present time will follow from this definition of the phrase, "medical attendance," as indicating the necessity for the presence of a legally qualified practitioner.

There is an added interest in the case in that the reversal by the appellate division was not unanimous, but was made with Justice Goodrich dissenting. It is this dissenting opinion that the Court of Appeals now accepts on the very day that Justice Goodrich read an important paper before the Medical Society of the State of New York on "Medicolegal Aspects of the Roentgen Rays." Justice Goodrich's personal relations to the medical profession are most intimate and it was his close knowledge of medical affairs that evidently guided him to the real solution of a vexed problem in the dissenting opinion which now becomes New York State law. It would seem clear that this more intimate acquaintance is of itself eminently desirable for both professions and that it will surely lead to the happiest results in a mutual understanding and mutual support for measures that manifestly involve the public good, yet are sometimes misunderstood by the public as being the index of narrow professional, or even selfish, purposes.

WORK AT THE SMALLPOX LABORATORY IN CLEVELAND.

A most gratifying tendency of the times is one exhibited by the boards of health in some of our larger cities. We refer to the appropriation of funds for the support of special researches bearing on the causation, nature and treatment of some of the diseases more prevalent in the cities concerned. A notable example in this direction is that set by the board of health of Cleveland. The authorities in that city have voted a liberal fund for the investigation of smallpox. The scourge from which the city has suffered for several years certainly justifies a large expenditure for this purpose. The Smallpox Research Laboratory, which has been established in Cleveland under the directorship of Dr. Wm. T. Howard, Jr., professor of pathology in Western Reserve University, has, during the past year, been the scene of active work carried on by the director and by several assistants under his supervision. The last number of the *Journal of Medical Research* contains several reports from this laboratory, among which are included "A Study of the Agglutinating Hemolytic and Endotheliolytic Action of the Blood Serum in Variola," by Dr. Howard, and "Studies on the Etiology and Pathology of Variola," "Streptococcus Pyogenes in Variola," "Bactericidal Action of the Blood Serum in Variola and in Varioloid," by Drs. Perkins and Pay. The titles of these papers alone indicate the high order and modern character of the work which is going on in the laboratory, and a perusal of their contents reveals an accuracy of observation, a comprehensiveness of grasp of the problems involved, and a thoroughness of research which make one feel that could more laboratories be conducted in this scientific way there would be less dissatisfaction than there is at present at the disposition which is made of public funds in connection with city boards of health.

The Cleveland authorities have done well to direct the researches toward a disease which, at this time, is of such great local importance, aside from the general interest which attaches to it. We have always thought it would be well if the clinicians of various cities would concentrate their attention on the diseases which most largely prevail in their midst, rather than dissipate their interests and energies by dividing their investigative work among the host of rare mala-

dies that they meet. The success of the studies of typhoid fever and malaria in Baltimore by the hospital physicians there illustrates what we mean. Smallpox is being studied in Boston and Cleveland. Let other cities pick out the problems which more particularly belong to them and progress should be rapid.

THE REORGANIZATION OF THE BRITISH MEDICAL ASSOCIATION.

The new plan of organization of the British Medical Association, which went into effect about a year ago, according to an editorial in the *British Medical Journal*, October 3, is proving decidedly successful and satisfactory. This is shown by the increased membership and by the greater activity in every part of the complex organization. The branches and divisions are showing an activity markedly in contrast to former conditions. The prospect is that if this is kept up it will in time bring the whole profession within the association. The new constitution of the British Medical Association which was adopted after considerable discussion is in many respects similar to that of the American Medical Association. The British representative body is similar in every respect to the House of Delegates of the American Medical Association; its members are elected by the "branches," which are—organically, not geographically—similar to our state associations. The "branches" are made up of the "divisions" which are their units, as the county society is the unit with us. The arrangement for including the colonial branches—Canada, Australia, etc.—is rather mixed and not easily comprehended by an outsider. The editorial refers to the good work that is being done by certain secretaries of branches and of divisions, and also by the general "organizing secretary," showing that the work of organization is being pushed with as much vigor there as with us. While their annual dues were increased from about $5 to about $6 to meet the increased expense—which action some thought would cause many to drop out—the work seems to be very successful and the membership is increasing rapidly to the point where it will include all who are eligible.

THE SIGNIFICANCE OF THE CENTRAL SULCUS OF THE CEREBRAL CORTEX FOR LOCALIZATION.

Opinion has swung to and fro for a long time as to the relation in which the cerebral sulci, and especially the central sulci of Rolandi of the two sides, stands to the localization of function in the cerebral cortex. The early view that functional areas are sharply marked off from one another by the various sulci gradually gave way before the doctrine that the sulci and gyri are of morphologic interest only and possess no delimiting functional significance whatever. Recent experiments made on motor localization in the cortex indicate, however, that at least for the sulcus centralis in the anthropoid apes, a very sharp localizing significance is maintainable. Sherrington has shown that if the animals be examined under precautions greater than those hitherto taken, no motor response can be elicited by stimulation behind the central sulci, all the cortical motor innervations apparently starting out from the anterior central gyrus situated in front of the sulcus. Sherrington's observations are being confirmed by other workers, and it has now become necessary to revise the well-known and time-honored charts of the motor cortex which clinicians use, and to bring them into accord with this newer knowledge. Even the upper and lower knees of the sulcus have definite localizing significance, one set of motor functions being constantly represented above each knee, another below. In how far time and further investigation will reveal a similar practical physiologic significance for the other sulci of the cerebral hemisphere it is impossible to say. It would certainly be convenient for the surgeon, especially if brain surgery goes on developing at its present rate, to have such clean-cut landmarks as the larger cerebral sulci to serve him as a reliable guide to functional areas when he has to apply his knife. It seems to us improper, however, that the exploration of other regions of the brain will ever yield us such definite and satisfying information concerning functions as the study of the motor areas has afforded us. Still, it is rash to make prophecy; new men may arise and new methods may be devised which will some time chart out for us even those great silent territories which Flechsig calls "association centers."

THE CORDITE EATERS.

It is a well-known fact that all confirmed users of stimulants and narcotics are not very particular as to the source of the agent they use. We have heard of sailors drinking off the liquor from a preserved admiral. One of the most peculiar methods of inducing intoxication, however, of which we have heard lately is the nitroglycerin habit in the British army. The material used in this instance is cordite. This is employed for the cartridges of small arms of that service, and consists of 58 parts of nitroglycerin, 37 of gun cotton and 5 parts of mineral jelly. It would seem that this combination would be rather awkward to masticate; nevertheless the British soldiers do not seem to find it so. In the *Journal of the Royal Army Medical Corps*, October, Maj. J. W. Jennings of the British service reports his observations in South Africa. It appears that the drug produces in the novice a racking splitting headache which may last for 24 hours or more, but the experienced user manages to obtain some satisfaction from its employment. When taken with beer or tea it seems to produce a heavy sleep, followed by stupor lasting approximately from 5 to 12 hours. It is difficult to awaken the subject, and when apparently awakened the cordite user does not seem to recognize his surroundings. There is a dull boring headache, slight facial twitching, protrusion of the eyes, a slowness of comprehension, and a disinclination to food, accompanied with a tendency to vomit. Taken in solution, as with tea, it appears to produce an exhilarating effect. If many take the beverage all begin talking at once, seeming anxious to inform each other of everything that has happened since their birth. This lasts for two or three hours, after which the effects seem to die away.

and sleep follows. If beer is taken during the excitement it brings on a combative and destructive tendency; the worst qualities of the individual are exhibited. Dr. Jennings gives a number of interesting personal histories and thinks it may be a new and rather peculiar form of vice. He does not see how the effects are likely to help a man to escape service unless it be by imprisonment as a hopeless lunatic or as a suicide. It was this claim that it was used to enable men to obtain their discharge that first called his attention to its use, but instead of being particularly for that purpose it seems to be a characteristic drug habit and a method of intoxication which has originated under special conditions. The subject is worthy of the investigation of military surgeons and officers generally. There must be many drug habitués who drift into the army, and if they can not get their ordinary intoxicant they take some other, as in this case, and add another to the already too extensive catalogue of "drugs that enslave."

CENSORSHIP OF NEWSPAPER ADVERTISEMENTS.

Justice Mayer of New York City, in a paper read at the 175th meeting of the Society of Medical Jurisprudence, October 13, on the subject of "Criminal Procedure Against the Unlawful Practice of Medicine," said some things that are not only of great interest to the medical profession, but that are worthy of arresting the attention of all serious-minded journalists of this country. He declared that the worst agency in New York to-day —as, of course, it is also in every large city throughout the country—in helping the person who sells either real or pretended abortion remedies, is the newspapers, for they make it possible to ensnare the unwary, the superstitious and the fearful. He adds: "I suggest that in the new school of journalism about to be established in connection with Columbia University there be a chair of advertising, and let it be taught to the young men of the newspaper profession that the first duty of a great newspaper is to censor its medical advertising." All those who are interested in the improvement of public morality will at once agree with this declaration of a distinguished member of the New York judiciary, who, with his opportunities as a justice of the Court of Special Sessions before which cases involving infractions of law in this matter are being constantly presented, is in a position to know by practical experience better than almost any one else the real causes that underlie the evils of which he complains. If it is possible it would be much better that this censorship he demands should be created by the voluntary good sense and the good will of the managers of newspapers than that it should be imposed on them by legal regulations; but those in control of some papers appear to consult only their commercial interests. The evils involved in this question have, however, of late years grown to such an extent as absolutely to require some regulation if public morality is not to suffer. As pointed out by Justice Mayer, the full extent of the criminality encouraged can not be estimated from the comparatively overt advertisements between the lines of which can rather easily be seen the criminal intent of the advertisers. Many apparently less reprehensible advertisements are only a cloak for criminal measures. "Many persons who advertise as palmists and clairvoyants," to quote Justice Mayer's words, "advertise simply to cover the giving out of medicines of the kind I have mentioned." Here is something for the responsible directors of newspaper policy to consider seriously. If their pretentions to help the cause of public morality mean anything, there is a clear method open to them by which to accomplish a great and lasting good.

Medical News.

DISTRICT OF COLUMBIA.

New Superintendent on Duty.—Dr. William A. White, Binghamton, N. Y., has assumed the duties of his position as superintendent of the U. S. Hospital for the Insane (St. Elizabeth's).

Medical School Opens.—The session of 1903-04 of Georgetown Medical School opened October 3 with addresses by Father Daugherty, director of Georgetown University, Drs. Joseph Tabor Johnson and George M. Kober.

American Public Health Association.—The thirty-first annual convention of the American Public Health Association of the United States, the Dominion of Canada, Mexico, and Cuba, will be held in Washington, October 26 to 30.

Woman's Clinic in New Home.—This institution, non-sectarian in character and a part of whose work is charitable, which was established thirteen years ago, has moved into its new hospital building at Thirteenth and T Streets, N. W. It is gathering a fund and is paying for its new home by degrees.

Society Elects Officers.—The Washington Obstetrical and Gynecological Society, at its meeting, October 16, elected the following officers: President, Dr. J. Wesley Bovée; vice-presidents, Drs. John F. Moran and Elmer H. Southron; recording secretary, Dr. J. Thomas Kelley; corresponding secretary, Dr. Edward E. Morse, and treasurer, Dr. John Van Rensselaer. The annual banquet followed.

Health Report.—The report of the health officer for the past week shows the total number of deaths to have been 92. There were 102 births and 13 stillbirths. There were 191 cases of typhoid fever, 18 cases of diphtheria, 18 cases of scarlet fever and one case of smallpox under treatment. The medical inspection of schools provided for at the last session of congress has begun. Printed regulations governing the medical inspection are being distributed to the teachers of the schools and the inspectors.

ILLINOIS.

Chicago.

Bequests.—The will of the late Henry J. Willing gives $5,000 each to the Chicago Home for Incurables and the Presbyterian Hospital, in the latter case to be used for the endowment of a bed in memory of his mother, Mary Jane Willing.

The Week's Deaths.—For the week ended October 17, the deaths numbered 459, 32 more than for the previous week and 14 more than for the corresponding week of 1902. The annual death-rate per 1,000 was 12.68. Acute intestinal diseases head the list with 51 deaths; other chief causes were: consumption, 45; pneumonia, 38; violence, 36, and heart diseases, 35.

Advisory Board Organizes.—The advisory board on management of county institutions has elected Dr. John B. Murphy president. The medical members of committees are as follows: Medical administration—Dr. Frank Billings, chairman, and Dr. Hugh T. Patrick; care of insane patients—Dr. Sidney Kuh, chairman, and Drs. Isaac A. Abt and Hugh T. Patrick; hospital for consumptives—Dr. Frank Billings, chairman, and Dr. W. A. Evans, and infirmary—E. R. LeCount.

Founded a Quarter of a Century.—The Chicago Gynecological Society held a banquet, October 16, in commemoration of the twenty-fifth anniversary of its foundation. In addition to an address by Dr. J. Henry Carstens, Detroit, reminiscent remarks were made by several members. The following officers were elected: Dr. Emil Ries, president; Drs. Joseph B. De Lee and Frank T. Andrews, vice-presidents; Dr. Palmer Findlay, secre-

tary, and Dr. Charles B. Reed, treasurer; Dr. Gustav Kolischer, pathologist, and Dr. Rudolph W. Holmes, editor.

Dr. Frank Billings Submits to an Operation.—Dr. Frank Billings, who has been ill for some time, but who has remained at work in spite of his condition, submitted to an operation, October 15. The procedure was in the nature of an exploration, the gall bladder being suspected as the cause of the trouble. Dr. L. L. McArthur, assisted by Dr. A. D. Bevan, performed the operation. A congestion of the liver was found with cholecystitis, and gall-bladder drainage was established. Dr. Billings is doing well, and it is hoped he will entirely recover.

Decrease in Infant Mortality.—A well-nigh incredible decrease in the deaths and the death rates of the two most dreaded diseases of childhood was demonstrated during the week, says the department of health.

Briefly stated, the records for sixteen years show that there were 2,152 deaths reported from scarlet fever during the eight years, 1887 to 1894 inclusive, while there were but 1,648 such deaths reported during the last eight years, 1895-1902 inclusive. In the first period there were 11,251 deaths from diphtheria and croup; in the second period only 7,093. The average yearly population of the first period was 1,050,000; of the second period it was 1,610,000—or 53.3 per cent. greater. In proportion to the increased population, the scarlet fever deaths decreased exactly 50 per cent. and the diphtheria and croup deaths decreased 59 per cent.

Reforms at Dunning.—The citizens' advisory board appointed several months ago to assist in the management of the county insane asylum, consumptive hospital and the infirmary, accompanied the County Board to Dunning October 14, and considered matters of scientific administration reform, and the new buildings and improvements needed. The plans as outlined by President Foreman, are as follows:

Erection of three new cottages for insane patients at an expense of $60,000.

Erection of five cottages for consumptive patients, with a central administration building, all structures to be connected by enclosed corridors, at an expense of $125,000.

Erection of a modern morgue and pathologic laboratory, with an amphitheater for lectures.

Erection of a training school for nurses and attendants.

The present consumption hospital to be converted into a hospital for the sick insane.

Erection in Chicago of a branch hospital for consumptives, where incurable cases may be treated.

Erection of a central power house, surrounded by shops, where the patients may be provided with light employment, such as making clothing, brushes and brooms for the use of the institution.

Installation of a vacuum system of steam heating in all institutions.

Light manual labor provided for all patients in good physical condition.

Books and games provided patients in the wards.

Baseball games, band concerts and other amusements to be provided for the patients in an enclosed space on the lawn in seasonable weather.

Clubrooms to be opened for the use of the nurses and attendants of the institutions.

Better protection against fire to be supplied.

The adoption of the latest scientific methods of treatment for insane patients.

A complete reclassification of insane patients by grouping along scientific lines.

Internes to be employed to assist the physicians in keeping a complete record of the history of cases.

MARYLAND.

Baltimore.

Deaths of the Week.—The deaths for the week ended October 17 were 168, an annual death rate per 1,000 of 15.61. Those from pneumonia rose to 18.

Bequests.—Mrs. Elizabeth A. Innes' will makes the following bequests: $4,000 to Church Home and Infirmary for the establishment of two beds; $500 to the Nursery and Child's Hospital.

Death in Narcosis.—A death occurred at the University Hospital, October 14, during the administration of ether for anesthesia. The patient, aged 22, had a severe cut in the palm of his hand. Shortly after administration was begun he began to vomit, the windpipe became clogged with food and he choked to death, notwithstanding an immediate tracheotomy.

Hospital Building Secured.—The faculty of Baltimore University School of Medicine has rented a building for hospital purposes. Drs. I. B. Kellar and E. C. Moriarty are resident physicians. Heretofore the school and hospital have been in the same building, the laboratory and dissecting room being elsewhere, but in the new arrangement everything will be concentrated in the college building except the hospital.

Personal.—On October 16 Dr. John D. Blake was elected chairman, and Dr. W. Edward Magruder secretary, of the Section on Clinical Medicine and Surgery of the Medical and Chirurgical Faculty of Maryland.——Drs. Hugh H. Young and Thomas Shearer have returned from Europe.——Dr. William Hewson, Baltzell, has returned from summering in Canada and Pennsylvania.——The friends of Dr. J. C. Hummer entertained him, October 11, on the occasion of his seventieth anniversary.

The Hebrew Hospital.—At the thirty-sixth annual Succoth festival banquet, October 11, $2,200 was raised for the Hebrew Hospital; $1,500 in legacies was reported during the year, and $1,735 in memorial gifts. The expenses for the year were $18,720, and the receipts $14,301. There were 296 inmates during the year, of whom 168 were discharged cured, 58 improved, 12 died; 127 operations were performed; 7,795 persons were treated in the dispensary; 8,692 prescriptions were compounded for the dispensary and 9,125 for the hospital.

MICHIGAN.

Personal.—Dr. James H. Reed, Battle Creek, has been reappointed lecturer of the third district of the state by the president of the state medical society.——Dr. N. Dudley Kean, Ishpeming, moved to Michigamme, succeeding Dr. Horace H. Loveland, who has gone East.

Lapeer County Society Election.—At the annual meeting of Lapeer County Medical Society the following officers were elected: Dr. Hugh D. McColl, Lapeer, president; Dr. Sparrow A. Snow, North Branch, vice-president; Dr. Peter Stewart, Hadley, treasurer, and Dr. Herbert E. Randall Lapeer, secretary.
